In the course of this trial every attempt was made to evaluate the toxic manifestations of streptomycin both clinically and biochemically. Fourteen patients, aged 2-60 years, served as subjects. The total doses of streptomycin varied from 0.4 g. given in 9 hours to 108 g. given in 90 days. All of the fourteen patients received streptomycin by intermittent intramuscular injection at four-hour intervals; in addition four of the fourteen patients received a daily dose of 0.2 g. intrathecally by the lumbar route, or into the cisterna magna. Preliminary intramuscular injection in one of us (G. B.) proved the streptomycin to be painful; hence at the start of the trial, and subsequently in those patients who complained of pain, streptomycin was administered in the presence of 0.5 per cent procaine hydrochloride. Animal protein enzymic hydrolysate and glucose, of each 1 g. per kg. of body-weight, were given by mouth to all patients on streptomycin to reduce liability to renal and hepatic damage.

Most patients were so seriously ill as to preclude systematic pathological investigations, but in most cases complete blood-counts (including differential leucocyte counts), hæmoglobin estimations, and urine

analysis were done at short intervals before, during, and after the experimental trial. The quantity of streptomycin circulating in the blood at four hours after the intramuscular injection of 0.2 g. of streptomycin was estimated from time to time throughout the trial by the slide technique with a strain of *Bact. coli*, c. n. 1360. Mean blood concentrations of 8 g. per ml. (minimum 4, maximum 16) were found. In cerebrospinal fluid twenty-four hours after intrathecal injection of 0.2 g. (two specimens), the concentration was 3.2 and 6.4 g. per ml.; after intramuscular injection alone no streptomycin could be detected in the cerebrospinal fluid.

No evidence of toxic effects on the hæmatopoietic system was observed and the total and differential blood-counts revealed no fluctuations outside the normal limits. The urines of five subjects showed the presence of leucocytes and epithelial cells during the experimental period; hæmaturias were not seen but red corpuscles were found in two cases. Albuminuria was recorded in one case. Casts were not found on any occasion.

No facial flushing or headache or any other evidence of histamine-like reaction such as described by Hettig and Adcock was seen.

One observation was made which seemed to us to be associated with the toxicity of pure streptomycin. This took the form of an increase of the normal diurnal excursion of the temperature range relative to the pyrexia. It was clearly demonstrated in three of the fourteen cases and showed no obvious relationship to any particular batch. It was not associated with myalgia or arthralgia; nor did any symptom appear with it.

In one case of advanced miliary tuberculosis with peritonitis and meningitis which came to necropsy a diffuse fatty degeneration of the liver was found. This may have been due to the tuberculosis or to the streptomycin. No dermatoses were encountered except a transient erythematous reaction on the dorsum of the hands of a worker ex-prisoner of war. It is doubtful if this condition was due to streptomycin. No toxic effects on the auditory nerve appeared.

On two occasions swelling and pain round the site of injection with regional adenitis developed after intramuscular injection but settled down with conservative treatment in three or four days.

Streptomycin in Experimental Plague

By J. W. HORNIBROOK

(From the *Public Health Reports*, Vol. 61, 12th April, 1946, p. 535. As abstracted in the *International Medical Digest*, Vol. 49, July 1946, p. 38)

THERE has recently been isolated from an organism resembling *Actinomyces griseus* a substance streptomycin which is more active against several organisms than is streptothrycin. Its toxicity is low (LD 0-35 mg.; LD 100-135 mg. per 20 gm. mouse with a preparation containing 30,000 units per gm.). In view of its possibilities as a therapeutic agent in human plague the following tests were made:

'The material used in these experiments contained approximately 200,000 units of streptomycin per gm.'

'The toxicity of this preparation was not properly tested because of a shortage of material. However, one 14 gm. mouse given 20 mg. as a 5 per cent solution intraperitoneally died in 20 minutes while one 15 gm. mouse receiving 10 mg. survived. A 16 gm. mouse given subcutaneously 40 mg. as a 5 per cent solution in distilled water survived.'

'Serial dilutions of the material were made in a liquid medium consisting of tryptose 1.5 per cent, sodium chloride 0.5 per cent and glucose 0.1 per cent. Dilutions were threefold and ran from 1/4,000 to 1/972,000. All tubes were inoculated with a broth culture of *Pasteurella* and incubated 3 days at 37°C. The turbidity was determined by turbidity.'

'In animal experiments mice weighing about 18 gm. were inoculated subcutaneously in the groin with 0.2 c.c. of a suspension of *Past. pestis* in 1 per cent peptone water. The inoculum contained up to 6,000 organisms as determined by plating methods. The streptomycin was inoculated intraperitoneally as a 1 per cent solution at various times and in varying amounts controls were given the same volume of normal saline at the time the test animals received the drug.'

'In two tests treatment was started 3 and 2 days respectively following inoculation with live organisms. Visible swelling at the site of inoculation was considered one of the signs of infection; therefore, at the time treatment was started animals not showing visible swelling in the groin (and those that had died) were excluded from the experiment. The remainder were treated. Sulfadiazine was also used for purposes of comparison.'

'At the end of 14 days from the time of inoculation all surviving animals were killed autopsied and the spleens cultured (circumstances prevented spleen culture in the last experiment). Animals dying during test were autopsied but spleen cultures were not made as decomposition made the isolation of pure cultures difficult. Spleen smears were made on all animals in which the post-mortem appearance was not typically that of plague in all its details. When typical bipolar organisms were found the spleen smears were considered positive. In diagnosing plague by post-mortem appearance the following signs were looked for: local lesions; enlarged lymph nodes; infected skin; soft, dark, enlarged spleen; lesions in the liver, lungs, and spleen. Spleen cultures were made by rubbing the cut surface of the spleen on the surface of a tryptose-glucose agar plate. A number of the positive cultures were checked by transfer of the typical colonies to tubes where fermentation of the various sugars was checked.'

'Streptomycin (both unheated and heated) inhibits the growth of *Past. pestis* in broth.'

'To test the prophylactic action of the drug mice were inoculated with plague subcutaneously, and varying amounts of streptomycin given intraperitoneally $\frac{1}{2}$ hour before and 17 and 24 hours after challenge. It seemed justifiable to consider mice dead 14 days following plague inoculation to have died from plague. However, autopsies were done with the following results: All of the animals which died showed evidence of plague on the basis of either gross pathology or spleen smears or both. Two of the four controls killed at the end of 14 days had local lesions and one had a bubo on the side opposite to the site of injection. One of the mice receiving dosage of 1 mg. and one receiving 0.5 mg. had enlarged inguinal nodes. The remainder were essentially normal. Spleens of all of the mice killed were negative on culture.'

'The above test was repeated, but the drug was given $\frac{1}{2}$ hour before and 24 hours after infection (making two instead of three doses). In addition, in one group treatment was not started until 2 days following infection. Results found at autopsy were as follows: All animals which died showed evidence of plague on the basis of either gross pathology or spleen smears or both. Surviving animals were killed on the fourteenth day. Three of the controls showed enlarged inguinal glands. One mouse receiving 1 mg. and one receiving 0.5 mg. had local lesions. One mouse given 0.5 mg. had both local and splenic lesions. One mouse given delayed treatment had local lesions. Spleen cultures of one mouse receiving 2 mg. and one receiving 0.5 mg. were positive for plague. All other spleen cultures from killed mice were negative.'

'In order to determine the effectiveness of streptomycin after the infection had developed 30 mice were challenged with live organisms. At 72 hours, 2 were dead and 3 showed no swelling at the site of inoculation; these were discarded. The remainder were treated. Two doses were given with a 24-hour interval between. All animals that died showed evidence of plague on the basis of gross pathology or spleen smears or both. All surviving animals killed on the fourteenth day

had enlarged nodes and one had a local lesion; the cultures from the spleens were negative.'

'The test appeared a bit drastic as several of the mice had died before treatment had started. In the following test treatment was started 48 hours after infection and a dose given daily for 6 days. In addition, a control was run with sodium sulfadiazine in the same dosage except for the first dose which was 5 mg. rather than 2 mg. Thirty-six mice were given live organisms and 48 hours later six were discarded as they showed no inguinal swelling. The remainder were treated. All mice which died showed evidence of plague on the basis of gross pathology or spleen smears or both. All mice killed on the fourteenth day showed swollen inguinal glands. Spleen smears were negative except for one streptomycin-treated mouse which showed an occasional organism.'

Traumatic Pulmonary Oedema Treated with Concentrated Plasma

By G. CLELAND

(Abstracted from the *Lancet*, ii, 9th November, 1946, p. 667)

PULMONARY oedema due to trauma carries a grave prognosis. Its causes include blast, petrol explosions, chest wounds, fat-embolism, accidental inhalation of noxious gases in industry and accidental overtransfusion with either blood or saline. Except in overtransfusion, accepted methods of treatment are not very successful.

Pulmonary oedema is characterized by severe respiratory distress and pronounced cyanosis. Large quantities of frothy mucus are thrown up into the trachea and well up through the larynx. Auscultation of chest detects coarse crepitations throughout which sound very close to the stethoscope. Danger to life lies in drowning through vast quantities of mucus in the alveoli and bronchial tree.

RATIONALE

The writer observed on many occasions that concentrated plasma administered intravenously reduces oedema in second-degree burns, apparently by its direct action in raising the osmotic pressure in the capillaries. If this can be done in traumatic oedema in other parts of the body, it should be possible in pulmonary oedema due to trauma, though not in pulmonary oedema produced by circulatory failure as a terminal event or due to overtransfusion.

METHOD

Many of the recognized methods of treatment for pulmonary oedema of traumatic origin are used, and concentrated plasma intravenously administered, is an addition to them, not a replacement of them.

Atropine gr. 1/50 is administered intravenously to diminish bronchial secretion to a minimum as soon as possible. It is considered that the atropine can have no direct bearing on the pulmonary condition.

So that maximal oxygenation may take place, as much of the mucus in the bronchial tree as possible must be removed. If the condition has only recently developed and consciousness has not been lost, the patient is encouraged to cough up as much of the mucus as possible. If the patient is either comatose or semi-comatose, the patient is laid supine, and the foot of the bed raised to encourage the mucus to flow towards the larynx. A tube is passed, under direct vision, into the trachea, and the mucus is sucked out. The injection of 'Coramine' 3-5 c.c.m. intravenously at this stage will often produce a temporary return of the cough reflex. This will bring still more of the mucus into the scope of the suction tube.

Oxygen is given continuously by a method which ensures the maximal concentration of that gas in the nasopharynx. The administration of concentrated plasma intravenously is begun coincidentally. In the

HAEMORRHOIDS

*No false
security in treatment.*

No narcotic, analgesic or local anaesthetic drugs enter into the composition of Anusol Haemorrhoidal Ointment, so that it may safely be prescribed for patients of all ages without fear of rectal

absorption of any toxic substance. Anusol Ointment contains mildly astringent medicaments in an emollient base. It relieves rectal congestion, allays irritation, and soothes inflamed tissues.

Convalescence

The building up of the system after illness, especially when anaemia and emaciation are present is definitely aided by the tonic—reconstructive action of Waterbury's Compound. This preparation presents products obtained by the enzymatic action of pancreatic ferments on cod liver oil, livers and spleens, malt extract and hypophosphites in a palatable form suited to the most fastidious palate. Waterbury's Compound improves the appetite and strengthens the digestive functions.

WATERBURY'S COMPOUND

Effective and Low Dosage Sulphonamide Therapy

with

IRGAFEN

(N-3, 4-Dimethylbenzoyl Sulphanilamide)

A well tolerated chemotherapeutic agent with definite action.
Total dosage 30-50% lower than that of other sulphonamides.

Indications :

Pneumonia, meningitis, B. coli infections, strepto- and staphylococcal infections, dysenteric enterocolitis, etc.

Tablets — Ampoules

VITAPHOR

**indicated in all cases of
VITAMIN DEFICIENCY**

VITAPHOR—the perfect TONIC is standardised to contain the following active Vitamins in each fluid ounce.

B₁ 450 International Units
C 1300 International Units
D₂ 1650 International Units
Plus
Glycerophosphate of Sodium,
Potassium Strychnine and
Magnesium

All combined with a suitable base which gives to this Tonic a pleasant and agreeable taste.

Prescribe Vitaphor in all cases of Convalescence from acute illness, in cases of undevelopment, faulty Nutrition and all "run down" conditions when the body is in a low state of health.

SMITH STANISTREET & CO. LTD.

MANUFACTURING CHEMISTS
(ESTABLISHED IN 1821 IN INDIA)

CALCUTTA BOMBAY MADRAS LUCKNOW AMRITSAR KARACHI

above-mentioned measures originally, double-strength plasma was used (the dried equivalent of 800 c.cm. of human plasma dissolved in 400 c.cm. of sterile water), latterly, triple-strength plasma has been used. The plasma is administered at a rate of about 80 drops a minute, and little difficulty is experienced in maintaining the flow if slight pressure is used. A dose of 400 c.cm. is usually adequate, but occasionally up to 800 c.cm. is required.

Other fluid intake should be limited.

Should it be proposed to use the method in accelerating recovery from pulmonary oedema as a result of overtransfusion, an adequate venesection is a necessary preliminary to the infusion of the concentrated plasma.

ILLUSTRATIVE CASE RECORDS

The five illustrative cases of pulmonary oedema due to various kinds of trauma showing the wide application of the method are described.

COMMENT

It appears clear that the initial improvement in these cases can be attributed to the standard measures applied. The outstanding advantage which appears to result from the use of concentrated plasma is the tendency for progressive improvement and the remarkable absence of any tendency for the condition to recur. No case has required more than one clearing of the trachea by suction.

DANGERS OF CONCENTRATED PLASMA

Reactions of various degrees of intensity may arise, but these do not differ from the reactions which may arise when normal plasma is used to replace plasma loss. Reactions only appear to be really dangerous when a serious hyperpyrexia develops. By careful observation this may be anticipated and the infusion stopped. If, on the other hand, it appears that death is a certainty from the pulmonary oedema unless administration of the plasma is continued, a fresh amount of plasma may be given through a fresh giving set and the pyrexia controlled by the usual cooling measures.

The Eye Bank

(Abstracted from the *Journal of American Medical Association*, 7th December, 1946, p. S62)

THE Eye Bank for Sight Restoration, Inc., established in 1944 in New York City, was conceived as a centralized agency where eyes could be systematically salvaged, preserved and redistributed to doctors who perform the corneal grafting operation. From twenty leading ophthalmologists originally to over two hundred and thirty-seven doctors at present are serving throughout the nation. Fifty-six hospitals participate in the project. Transportation has been made available through the co-operation of the American Red Cross and various airlines. In addition to supplying corneas for surgical procedures, the eye bank has carried on a widespread programme of education both of the public and of physicians through the press, magazines, the radio and the distribution of literature. During the first year of activity nine scholarships were awarded, two fellowships have been granted. The facilities of the Ayer Laboratory for Corneal Research have been made available for routine and investigative work. Here the eyes are received, given a prompt and careful examination to determine the condition of the corneal tissue, put under a twenty-four hour culture test and then sent with directions to doctors for grafting operations. Research problems include studies on corneal preservation, techniques of transplanting the vitreous humour and investigations of the metabolic and histologic properties of the eye. An information kit of educational material may be obtained by writing to the Eye Bank for Sight Restoration, Inc., 210, East 64th Street, New York 21.

LEUKÆMIA AND WAR SERVICE

(Abstracted from the *British Medical Journal*, 21st. December, 1946, p. 970)

A DRIVER in the Royal Army Service Corps was posted to Belsen Camp soon after it was discovered. He stayed there for a few days, and seven days later, he fell ill with an acute type of leukemia. He was flown to England but died in about four weeks. His widow claimed a pension. Before 1944, she would have had to prove that the death had been attributable to war service, but by the Royal Warrant, which came into force at the end of 1943, claimants are in a much stronger position, for the Minister must now prove that the prescribed conditions have not been fulfilled, i.e. that the death must have been due to or hastened by a wound, injury, or disease attributable to war service, or the aggravation by war service of a pre-existing trouble. The claimant is given the benefit of all reasonable doubt. Moreover, as leukemia was not noted in any medical report on the driver at the beginning of his service, the widow had a presumption in her favour that it was attributable to his service. The Minister and the Pensions Appeal Tribunal both found against her and she took the case to the High Court.

The Medical Services Division of the Ministry had stated that leukemia was a condition in which there was an overgrowth of the white cells of the blood; there was no evidence that the disease was caused by any known organism; the changes which occurred were generally regarded as neoplastic, affecting the white-blood-cell-forming tissues; and the disease ran a characteristic course which in the acute type was rapidly fatal. This, said the judge Mr. Justice Denning, told the court nothing about the cause. The Division concluded that leukemia was not a condition of which the onset or progress could be regarded as affected by conditions of service, including those which the widow alleged. If, said the judge, the earlier part of this opinion had contained material sufficient to warrant such a conclusion, he would have been unable to interfere with that evidence, but he found nothing to do so in any way. Considering that the disease had shown itself after the man had stayed in Belsen Camp, and in view of the strong presumption created by the absence of any mention of it in an initial medical report, the medical evidence against the claim must be particularly cogent in order to defeat it, and must establish clearly that all external causes could be excluded. This it had not done. He therefore reversed the finding of the tribunal and granted the pension.

Reviews

MEDICAL ELECTRICITY FOR MASSAGE STUDENTS.

—By Hugh Morris, M.D., D.M.R.E. Third Edition. 1946. J. and A. Churchill Limited, London. Pp. viii plus 348, with 114 illustrations. Price, 2s.

THE third edition of Dr. Morris' book will be welcomed by students taking courses in massage and physiotherapy.

The first twelve chapters contain a concise and lucidly written account of the underlying principles of electricity. Chapters 13 to 20 deal very adequately with the use of galvanic and faradic currents. The section on muscle testing is particularly well done.

Latter chapters deal with diathermy, including an adequate account of short-wave therapy.

The final sections of the book deal with ultra-violet and infra-red radiation. A useful section at the end deals with individual diseases and their treatment by electro-therapeutic methods.

The book is quite one of the best that has appeared on the subject. It is written in very simple language, and will be much appreciated by physiotherapists.

G. G.

PROCEEDINGS OF THE ALL-INDIA OPHTHALMOLOGICAL SOCIETY. Volume VIII. Session 1945. Printed at the Madras Publishing House, 19, Mount Road, Madras. Pp. xx plus 176. Illustrated

THIS is the report of the more important papers and discussions sent to, or delivered at, the meeting of the All-India Ophthalmological Society, held in Hyderabad, Deccan, in March 1945. The main section deals with a Symposium on Glaucoma. Among the more interesting of the other papers are: 'A Type of Conjunctival Affection associated with Staphylococcus Citreus', by B. N. Bhaduri; 'Detachment of the Retina with Involvement of the Macula'—Report of Two Cases, by K. Sen; 'Local Use of Sulfapyridine Powder in Eye Affections', by C. N. Shroff; and 'Sub-Conjunctival Sulphonamide Therapy in Ocular Infections', by H. D. Dastoor.

E. J. S.

AN INTRODUCTION TO BIOCHEMISTRY.—By W. R. Fearon, M.A., Sc.D., M.B. Third Edition. 1946. William Heinemann (Medical Books) Limited, London. Pp. x plus 569. Price, 21s. net

It delights us to handle the new edition of Fearon's Introduction to Biochemistry, the predecessor of which we had the pleasure of reviewing several years ago.

One of the first things which strike the reviewer is that in the present edition the author has revised the book in a very thorough manner and has brought before the students the recent advances in some of the important and interesting subjects, like food absorption, acid-base balance, carbon-dioxide transport, amino acids, blood chemistry, etc. Chapter 14, dealing with Nutrients, has almost completely been rewritten and its sub-section on vitamins and pro-vitamins has been brought up on the lines of our up-to-date knowledge on the subject. A new chapter on Tissue Chemistry has been added.

The book appears to us to be admirably suitable for students going up for higher studies on the subject. It has been written in an excellent style and the author has comprehensively dealt with the fundamental processes going on in the human body, avoiding lengthy discussions on debated points which are often confusing to the student.

As an admirable summary of the recent advances in biochemistry, the book would be helpful not only to medical students but also to all who want to be introduced to the subject of modern biochemistry.

J. P. B.

TEXTBOOK OF MIDWIFERY.—By W. Shaw, M.A., M.D. (Cantab.), F.R.C.S. (Eng.), F.R.C.O.G. Second Edition. 1947. J. and A. Churchill Limited, London. Pp. xiv plus 649, with 4 plates and 235 text-figures. Price, 21s.

THIS is another excellent publication by Messrs. J. and A. Churchill Limited, London. Mr. Shaw's productions have a special feature of their own. They are written from the personal experience of a veteran professor working in an institution hoary with the best traditions of scientific medicine.

Recent works on such important subjects like 'Erythroblastosis Foetalis'—Penicillin Therapy, etc., have been incorporated for the benefit of students going up for examinations. At the same time the usual paraphernalia of a textbook of obstetrics, viz, the description of the mechanism of labour, discussion on the

toxæmias of pregnancy, prevention and treatment of puerperal infections have also found their places.

In the preface, the author says, 'I have also endeavoured to point out the different and often conflicting opinions which are held in various forms of treatment'. His endeavour will be well appreciated not only by those for whom the book is meant but also by others who try to follow his times in their routine work of teaching.

It is difficult to single out any chapter for special praise. For brevity of description without sacrificing the completeness of details, the section on Analgesia and Anaesthesia during child birth may be mentioned. This is perhaps the first textbook written in English to write about the use of 'Pethidin', a very recent acquisition in the obstetrician's armamentarium.

A new nomenclature 'Pathology of Pregnancy' has been used. The toxæmias of pregnancy should be included under this head, though they have been dealt with in a separate chapter.

It is difficult to overpraise this book. In the chapter on Operative Midwifery 'Forceps Application' has been elaborately dealt with. This is what it should be. Destructive Operations on the Fœtus have been dealt with rather sparingly. Better and detailed description of the management of such operations will be appreciated by those of us who may have to tackle cases where there have been no antenatal care and improper conduction of the early stages of labour.

The get-up and printing of the book is in the best way of Messrs. Churchills' publications.

M. S.

DISEASES OF THE SKIN.—By James H. Sequiera, John T. Ingram, and Reginald T. Brain. Fifth Edition. 1947. J. and A. Churchill Limited, London. Pp. xii plus 782, with 63 coloured plates and 380 text-figures. Price, 63s.

MEDICAL men interested in diseases of the skin have grown grey while waiting for a new edition of this famous book. It has appeared at last, after 20 years! In this time two of the original authors' students have become his colleagues and collaborators.

The old ground has been covered as thoroughly as ever before and with the same mastery in summing up controversies and the same boldness in giving the verdict. The information on newer fields, however, cannot be said to be as complete. For instance, Reiter's syndrome and Beheet's syndrome are not in the index; the newly described infective agent of Granuloma Venereum has not replaced the inclusion body; malaria therapy of Pemphigus has not been given; and lesions of the tongue in Hodgkin's disease have not been mentioned.

The first 31 pages dealing with Introduction, Histology and Physiology of Normal Skin, and Morphology of Skin Diseases condense admirably the basic facts which although well known in pre-clinical days grow hazy steadily, with the passage of time, in a busy medical man's life. The last 17 pages give an equally admirably condensed account of physiotherapy.

The tropical diseases of the skin continue to be well represented. This fact makes the book particularly useful to medical men in India.

The 380 black-and-white illustrations and 63 coloured plates are excellent.

The book remains a standard English work on dermatology and can be recommended confidently to anyone requiring information on the subject.

S. D. S. G.

HERMAPHRODITOS: THE HUMAN INTERSEX.—By A. P. Cawadlas. Second Edition, Revised and Enlarged. William Heinemann (Medical Books) Limited, London. Pp. x plus 81. Illustrated. Price, 15s.

THE theme of this book is that feminized men and masculinized women are often seen but hermaphrodites hardly ever; that in fact all human beings are intersexual possessing both gonads, one developed and the

other rudimentary; that all men secrete the female hormone, oestrin; and that only imbalances of intersexuality constitute a morbid state. The theme is stated after a composite atmosphere of classics, history and biology has been created.

We are told that the libido, at its appearance slightly before puberty, is bisexual. There are, therefore, such considerations to engage one's attention as the Balance Sheet of Sexual Characters, the Genetic Sex and the Pragmatic Sex.

Accidental hormonal imbalance has been considered. Cirrhosis of the liver may cause gynecomastia as the oestrin secreted by the male is destroyed by that organ (p. 50): the undestroyed hormone builds up a female breast.

The institution of homosexuality amongst the ancient Greeks has merely been mentioned. In view of the recent comment on this human failing, in the British and American current medical literature, more was expected in a book with such a title. The statue of this name, frank in conception and perfect in execution, is essentially an embodiment of the Greek sentiment.

Examples of male and female inter-sexual biotypes with imbalance have been given from old records.

Therapeutics of imbalance include hormone, vitamins, suggestion and surgery.

The book which is in its second edition is an expansion of the author's Thomas Vicary Lecture on Hermaphroditism.

S. D. S. G.

MEDICAL RESEARCH COUNCIL. SPECIAL REPORT SERIES NO. 254. AN EXPERIMENTAL STUDY OF RATIONING.—By R. A. McCance and E. M. Widdowson. 1946. Published by His Majesty's Stationery Office, London. Pp. 61. Price, 1s.

THIS is the account of an interesting experiment which was carried out by the authors at the outbreak of war in September 1939 to discover whether English men and women could live and thrive mentally and physically if they were subjected to a feeding regime in which fat, sugar, flesh foods and other rationed articles of diet were severely restricted. The experimental diets were planned to meet much more serious blockade conditions than were actually experienced in the war. The calories were not limited, and they had enough proteins, though low in essential proteins, large amounts of carbohydrate and sufficient minerals, but had very little fat in them. It was found that the subjects of the experiment, who were all young people, required a little time to adapt themselves to the changed conditions. This they did by increasing their consumption of unrationed foods which were essentially potatoes, green and root vegetables, bread of 92 per cent extraction and fortified with calcium carbonate. The majority of the subjects made satisfactory adjustments, and once they had done so they were content. Their health remained good during three months' period of the experiment at the end of which they were able to take prolonged and severe physical exercise without undue fatigue.

The report is a valuable contribution to our basic knowledge of nutrition and should be widely read. It shows how in times of stress and qualitative restriction of food a diet can remain compatible with good health, so long as it conforms to certain well-defined nutritional principles.

R. N. C.

MEDICAL RESEARCH COUNCIL. SPECIAL REPORT SERIES NO. 255. 'CHEMOTHERAPEUTIC AND OTHER STUDIES OF TYPHUS.'—By M. Van Den Ende et al. 1946. Published by His Majesty's Stationery Office, London. Pp. 246. Illustrated. Price, 12s. 6d.

THIS report records the result of clinical and laboratory studies of typhus fever, carried out in relation to investigation on the chemotherapy of the disease. Out of some 238 drugs (listed in Appendix B)

which have been tested against experimental infection in mice two compounds designated V147 and V186 were selected for special investigation as these were found to be very promising in laboratory animals. They belong to sulphonamide group of drugs but differ from them in some respects. Section I describes studies of the toxicity of these two drugs. The account of an expedition to North Africa and Italy forms the largest part of the report (section II) and it was in these two areas that clinical trials were carried out during the war by a British Army Typhus Research Team with the co-operation of various authorities. Though, unfortunately, the drugs did not prove effective, an admirable opportunity was obtained for making detailed clinical and pathological observations which are recorded in the report, giving a picture of louse-borne typhus as seen in North Africa and Naples. The case reports of typical typhus patients are given in Appendix A to this monograph. The last three sections describe a number of important studies on the immunology of typhus fever which were made at the National Institute for Medical Research and the R.A.M.C. Emergency Vaccine Laboratory.

This is a valuable monograph on typhus.

R. N. C.

BULLETIN OF THE HEALTH ORGANIZATION. Volume XI, 1945. Published by the Health Organization, League of Nations, Geneva. Pp. 235. Price, 6s. or \$1.50

THIS is a complete bibliography covering not merely the period during which the Bulletin has appeared but the whole of 25 years of existence of the Health Organization. It will serve as a record of the work of the Organization and as a tribute to the many collaborators all over the world as well as a guide to technical studies on varied subjects carried out under the auspices of the Health Organization of the League of Nations.

R. N. C.

THE TREATMENT OF BRONCHIAL ASTHMA.—By Vincent J. Derbes, M.D., and Hugo T. Engelhardt, M.D., F.A.C.P. With chapters by a panel of contributors. 1946. J. B. Lippincott Company, Philadelphia and London. Pp. xv plus 466, with 61 illustrations. Price, 48s.

THAT it should be necessary to get 19 contributors to write a book on bronchial asthma covering about 450 pages shows the enormous importance which the disease has attained. As it appears from the historical introduction, asthma was recognized by the ancient Greek physicians as a distinct clinical entity, and it is interesting to know that Jerome Carden in 1552 cured the Archbishop of St. Andrews of asthma by insisting on, among other things, avoidance of feather beds—a forecast of allergy, and that three centuries ago Thomas Willis described bronchial spasm as one of the causes of asthmatic attacks. The book is divided into two parts. The first has eight chapters devoted to basic fundamentals, viz. ætiological factors, anatomy and physiology of the respiratory tract, pathology, immunology, climate and weather effects, etc., while the fifteen chapters of the second part deal with clinical aspects, diagnosis and treatment. There is hardly any aspect of the disease which has been left untouched by the authors, and all our knowledge on the subject has been assembled and presented from the general practitioner's point of view. The book can certainly be recommended to all interested in the field.

R. N. C.

FORENSIC CHEMISTRY.—By Henry T. F. Rhodes. (Second Edition, Revised.) Chapman and Hall Ltd., 37 Essex Street, W.C.2, London. Pp. 164. Price, 15s.

THIS is the second edition of a little book in Forensic Chemistry in English by a worker in France. It is much more than toxicology which is usually associated with forensic medicine.

Certain suggestions for the next edition offered in the review of the last edition (1940) can be repeated: (1) Removal of certain obscurities (page 11, para 2; page 70, last para; page 81, para 6; page 154, para 3) and unnecessary restrictions (page 155, para 4, not keeping sulphuric acid in glass bottles). (2) Differentiation between blood groups and blood types. (3) Clarification of descriptions by re-arranging types of headings. A sub-heading in *capital* letters should not fall under a heading in *small* letters as occurs on p. 112, under (g). The Examination of the Forged Documents, on page 106 falls 'The Date of the Document' on page 112. (4) Inclusion of sweat analysis undertaken for turf clubs. Samples used to be sent to France from all over the world in suspected drugging of horses.

The number of pages in this edition has been reduced by 50, by reducing the margin. The text now appears rather overcrowded and therefore overwhelming.

A useful addition to the library of forensic literature.

S. D. S. G.

ESSENTIALS OF ALLERGY.—By Leo H. Crlep, M.D. J. B. Lippincott Co., Philadelphia, London and Montreal. Pp. 381. Price, 30s.

THIS little book provides an ideal introduction to the intriguing subject of Allergy. This condition is responsible for about 10 per cent of cases in a physician's practice in America and there is no reason to suppose that the percentage is less in India.

The simple procedures of testing and treating the allergic states are given in detail and case reports provided. The account avoids scrupulously the metaphysics of immunology which even a man of leisure finds dull and which is never likely to interest busy practitioners. The bibliography for the interested readers is not wanting.

The recipes for special diets are so good that the latter are not likely to be suspected as special. Here and there the cookery book language might have been paraphrased (e.g. '2 eggs separated', 'Beat egg white until stiff and dry', 'Fold white into egg yolk mixtures', page 131).

The get-up is excellent. The price could be lower.

Abstracts from Reports

ANNUAL REPORT OF THE PENDRA ROAD SANATORIUM, PENDRA ROAD, BILASPUR DISTRICT, CENTRAL PROVINCES, FOR THE YEAR, 1945-46

The sanatorium is two and a half miles from Pendra Road Railway Station of the Bengal Nagpur Railway. It offers treatment to consumptive patients on modern scientific basis. The number of beds available in 1916 when it was opened was 12. At present, it has accommodation for 160 patients, 66 are in separate cottages and 94 in 5 general wards. Of the latter, 49 are free beds reserved by the Central Provinces Government, various donors and associations.

The number of patients admitted during the year was 195. The daily average number of patients treated

has been 160. 58.7 per cent of the patients on admission were advanced cases of tuberculosis. Out of 207 patients discharged, 162 patients were found to be suffering from pulmonary tuberculosis. 120 or 74.1 per cent were discharged with positive results, viz, 26 as 'arrested', 78 as 'much improved' and 16 as 'improved'. Among the patients discharged with negative results, 13 were discharged as 'stationary', 14 as 'worse' and 15 as 'dead'.

There is an after-care colony for poor ex-patients of the sanatorium. It is now only in its infant stage but with financial support it is hoped to extend its usefulness.

A REPORT OF THE SEVENTY-SECOND YEAR'S WORK IN INDIA AND BURMA OF THE MISSION TO LEPROS FOR THE YEAR SEPTEMBER 1945 TO AUGUST 1946

THE Mission has many Homes and aided Houses all over India, in which the total number of leper inmates, at the end of December 1945, was 9,221 excluding 854 healthy children. In addition, well over 11,000 out-patients received treatment. The report is illustrated with photographs and gives some details which show the fine work that is being done in the various Homes. The Mission has also leprosy homes and hospitals in Burma and Ceylon and supports work for sufferers from leprosy in China, several countries in Africa and in other lands. The expenditure for all purposes in 1945 was approximately Rs. 16,22,046.

INADEQUACY OF MEDICAL EDUCATION IN INDIA

SIR,—On graduation one finds that when confronted with first few cases all that was taught and emphasized in medical colleges is hardly sufficient and necessary for equipping one for general practice. In fact, the knowledge that is being imparted these days in the medical institutions makes it necessary for every fresh graduate to put in quite some time to acquaint himself with the requirements of general practice. This is not only my view: it is shared by graduates from Agra, Lucknow and other places as well.

Things being so, I might suggest a few points for the consideration of those who are now actively planning to improve the medical education.—

(1) That in every subject half of the examiners should be general practitioners. This is worth considering because the highly qualified staff in the colleges while teaching their subjects always try to (may be unconsciously) make out of their pupils specialists, which is unfair. Most of these highly qualified teachers are appointed examiners and to put below a few of the questions asked by them will not be out of place here:—

1. Retinitis pigmentosa in ophthalmology.
2. Types of joints in sewage pipes and their construction in hygiene.
3. Pneumonic plague and its treatment in medicine.
4. Arsenical dermatitis in medicine.

The appointment of general practitioners, as half the number of examiners will serve as a deterrent to the specialists doing injustice to the students in the degree examinations.

(2) In order to prevent further and avoidable wastage of man-hours, a series of lectures in every subject and practical demonstrations by general practitioners should be instituted in colleges so that the graduates may have some ideas of the rôle he is to

play as a general practitioner and the problems he has to confront after graduation.

(3) The suggestion of imparting instructions in a practical manner about general nursing should also carefully be considered.

Yours, etc.,

H. C. JAIN, M.B., B.S.

CHANDAN NIWAS,
AJMER,
26th March, 1947.

[Note.—Probably by every subject the writer means every clinical subject. The general practitioners are and will remain the back-bone of the profession. To force them, however, to examine in non-clinical subjects will not be fair.—EDITOR, I.M.G.]

Any Questions

POTENCY OF PENICILLIN

SIR,—I am to say that penicillin sodium is usually found in the form of dry powder or lumps. But in some phials it is found as a firm cake adherent to the bottle. As it is said to be very hygroscopic, and from the appearance of the cake it appears that it has absorbed some moisture and has been turned into a firm and adherent cake, it may be considered to have lost its efficacy. I request you to kindly let me know precisely the therapeutic value of such a stuff.

Yours, etc.,

BALWANT SINGH BAJWAH, L.S.M.F.

CIVIL HOSPITAL,
TEHRAN (U. P.).

[Commercial penicillin vials contain penicillin in a 'lyophilized' state, which means that the watery portion has been removed from the antibiotic filtrate by a special process involving drying under a state of refrigeration. This method leaves the material sometimes in the form of a shell adhering to the glass sides of a vial or a foam with minute pores on the surface. This is therefore no indication that the material has lost potency or absorbed moisture. Provided the seal of the vial is intact and the material inside is freely soluble in distilled water or saline, it can be safely used in therapeutics.—B. M.]

Service Notes

APPOINTMENTS AND TRANSFERS

LIEUTENANT-COLONEL M. K. AFRI, C.B.E., Deputy Director, Malaria Institute of India, Delhi, is appointed to officiate as Director of the Institute, with effect from the 1st March, 1947, *vice* Major-General Sir Gordon Covell on leave.

Lieutenant-Colonel C. Mani, on return from deputation to Europe and Egypt, assumed charge of the post of Additional Deputy Public Health Commissioner with the Government of India on the forenoon of the 1st May, 1947.

Lieutenant-Colonel A. S. Garewal, Inspector-General of Prisons, Central Provinces and Berar, is appointed to hold the charge of the current duties of the office of the Inspector-General of Civil Hospitals, C.P. and Berar, in addition to his own duties with effect from 12th May, 1947.

Major J. N. Ghosh, M.C., has been appointed as Medical Adviser (Pensions) (D.A.D.M.S.), Defence Department (Pensions Branch). Dated 20th November, 1946.

Major T. Somerville is appointed to officiate as Assistant Director, Central Research Institute, Kasauli, with effect from the 1st January, 1947, *vice* Lieutenant-Colonel W. J. Webster, C.B.E., M.C., granted leave pending retirement.

Major P. V. Krishnamurti is appointed Medical Adviser (Pensions) D.A.D.M.S., Defence Department (Pensions Branch). Dated 31st March, 1947.

Major G. H. K. Niazi, Deputy Assistant Director-General (Medical Stores), Medical Store Depot, Raipur, is transferred as Deputy Assistant Director-General (Medical Stores), Medical Store Depot, Bombay, with effect from the afternoon of 2nd April, 1947.

Major R. B. Sule, M.C., is appointed as Medical Adviser (Pensions) (D.A.D.M.S.), Defence Department (Pensions Branch). Dated 5th April, 1947.

The undermentioned officers of the I.M.S. (E.C.), revert from the I.A.M.C. and are seconded for service in the Royal Indian Air Force :—

Captain D. M. Marker. Dated 23rd December, 1946.

Captain P. R. Kutty. Dated 31st December, 1946.

Captain (A./Major) H. K. Khalil. Dated 7th January, 1947.

Captain P. R. Govind. Dated 7th January, 1947.

Captain P. Dharmaraju. Dated 8th January, 1947.

Captain Z. Khan. Dated 3rd February, 1947.

Captain S. B. H. Gardezi. Dated 7th February, 1947.

8th February, 1947

Captain M. A. Khan. Captain R. Arunchalam.

LEAVE

Major-General Sir Gordon Covell, C.B.E., K.H.F., Director, Malaria Institute of India, Delhi, is granted leave *ex-India* from the 1st March, 1947 to the 19th October, 1947, preparatory to retirement.

Lieutenant-Colonel H. W. Mulligan, Director, Central Research Institute, Kasauli, is granted combined leave *ex-India* for 12 months, with effect from the 14th April, 1947.

SECONDED TO THE INDIAN ARMY MEDICAL CORPS
(Emergency Commissions)

Captain P. K. Das. Dated 3rd April, 1946.

Captain Dossabhoy Bomanji Parakh. Dated 16th April, 1946.

Captain Naunihal Singh. Dated 23rd April, 1946.

Captain P. N. Rama Chandra Setty. Dated 25th April, 1946.

Captain Brajamadhab De. Dated 26th April, 1946.

Captain Jagdish Chandra Sharma. Dated 1st May, 1946.

Captain Arulappan Paul Devadoss. Dated 6th May, 1946.

Captain Bibhuti Bhushan Sarkar. Dated 6th May, 1946.

Captain Vadakkedath Krishnankutty Menon. Dated 10th May, 1946.

Captain Syed Ghaus Mohammad Shah. Dated 21st May, 1946.

Captain Arani Parthasarathy Babu. Dated 29th May, 1946.

Captain Nerur Gopala Aiyangar Raghavan. Dated 31st May, 1946.

Captain Poosapati Ragliunadharaju. Dated 4th June, 1946.

Captain Varnasi Peddavadhani Somayazulu Sarma. Dated 4th June, 1946.

Captain Natwarlal Chamanlal Mehta. Dated 10th June, 1946.

Captain Homi Ardeshir Press. Dated 17th June, 1946.

Captain Taher Trebally Harianavala. Dated 22nd June, 1946.

Captain Hem Chandra Sen Gupta. Dated 30th June, 1946.

Captain Priya Gopal Bhattacharya. Dated 8th July, 1946.

Captain Sukomal Roy Chowdhury. Dated 17th July, 1946.

Captain Ambalavatath Koitayi Haridass. Dated 29th July, 1946.

Captain Muhamad Husain Qamar. Dated 29th July, 1946.

Captain Bibhas Chandra Mitra. Dated 8th August, 1946.

Captain Radhicanranjan Chaudhuri. Dated 21st August, 1946.

Captain Sanatan Nandi. Dated 26th August, 1946.

Captain Albert Bernard Rustom. Dated 28th August, 1946.

Captain Sachi Kanta Sen. Dated 31st August, 1946.

Captain Kuruganti Narayana Sastri. Dated 25th September, 1946.

Captain Ouseph Francis. Dated 25th September, 1946.

Captain Suraj Prakash. Dated 27th September, 1946.

Captain Harris Arthur Satya Joseph. Dated 30th September, 1946.

Captain Bashir Ahmad Butt. Dated 6th October, 1946.

Captain Kadayam Sreenivasa Iyer Sankaran. Dated 10th October, 1946.

Captain R. C. Mitra. Dated 10th October, 1946.

Captain Mangudi Kailasa Swaminathan. Dated 14th October, 1946.

Captain Mohammad Abdur Rahman Azhar. Dated 27th October, 1946.
 Captain Murugappa Somasundaram. Dated 27th October, 1946.
 Captain Radha Krishan Arora. Dated 27th October, 1946.
 Captain Syed Balaghat Hosain. Dated 27th October, 1946.
 Captain Sonri Rajan. Dated 30th October, 1946.
 Captain Rustom Mervanji Dastur. Dated 31st October, 1946.
 Captain Balkrishna Govind Sarnobat. Dated 1st November, 1946.
 Captain H. P. Rao. Dated 2nd November, 1946.
 Captain Padinjariil Zachariah Abraham. Dated 3rd November, 1946.
 Captain Dilip Kumar Sen. Dated 4th November, 1946.
 Captain Balwant Singh Sachdev. Dated 5th November, 1946.
 Captain Akshoy Kumar Ray. Dated 21st November, 1946.
 Captain Jhamandas Nichani. Dated 24th November, 1946.
 Captain Mohammad Qasim Ali. Dated 24th November, 1946.
 Captain Sevilimedu Krishnamachari Srinivasan. Dated 24th November, 1946.
 Captain Hari Laxman Marathe. Dated 25th November, 1946.
 Captain M. A. Hamid. Dated 26th November, 1946.
 Captain S. K. Menon. Dated 27th November, 1946.
 Captain Dibakar Manna. Dated 1st December, 1946.
 Captain Nand Gopal Mukerjee. Dated 1st December, 1946.
 Captain Chintaman Ramchandra Shringapur. Dated 2nd December, 1946.
 Captain Hem Chandra Bhattacharyya. Dated 7th December, 1946.
 Captain Nagaratnam Rajasekharan. Dated 12th December, 1946.
 Captain Subodh Kumar Rana. Dated 13th December, 1946.
 Captain Iswar Chandra Misra. Dated 14th December, 1946.
 Captain Krishnaswami Kalyana Sundaram. Dated 15th December, 1946.
 Captain Ganesh Pandurang Sathie. Dated 16th December, 1946.
 Captain B. S. Suxena. Dated 17th December, 1946.
 Captain Sahdev Virmani. Dated 19th December, 1946.
 Captain Umapati Mazumder. Dated 19th December, 1946.
 Captain Mangudi Kailasa Tyagarajan. Dated 20th December, 1946.
 Captain N. L. Jha. Dated 20th December, 1946.
 Captain Sunil Kumar Ray. Dated 22nd December, 1946.
 Captain Khurshid Alam Malik. Dated 23rd December, 1946.
 Captain Khagendra Nath Sen Gupta. Dated 24th December, 1946.
 Captain Nand Kisore Khanna. Dated 25th December, 1946.
 Captain Ram Ekbal Sinha. Dated 25th December, 1946.
 Captain Sunil Chandra Datta. Dated 25th December, 1946.
 Captain D. P. Chakrabartty. Dated 27th December, 1946.
 Captain V. N. Chaturvedi. Dated 30th December, 1946.
 Captain Naresh Chandra Talapatra. Dated 1st January, 1947.
 Captain Sham Singh Sekhon. Dated 3rd January, 1947.

4th January, 1947

Captain J. A. Thomas.
 Captain Satya Parkash.
 Captain A. G. Rao. Dated 5th January, 1947.
 Captain Puttige Ramchandra Sastry. Dated 6th January, 1947.
 Captain D. S. Pathre. Dated 7th January, 1947.
 Captain Kandasamy Minakshi Sundaram. Dated 8th January, 1947.
 Captain M. B. Kekre. Dated 8th January, 1947.
 Captain P. K. K. Menon. Dated 9th January, 1947.

11th January, 1947

Captain M. De Azavedo.
 Captain Gurbachan Singh Lamba.
 Captain Shaikh Mohamed Yousuf.
 Captain Ramrao Vinayak Waingankar. Dated 14th January, 1947.

15th January, 1947

Captain Birendra Narayan Ray.
 Captain S. S. Muthanadam.
 Captain Thayamballi Payyanadan Balkrishnan.
 Captain Anpingsingh Khengzari Jadeja. Dated 17th January, 1947.
 Captain Jagannath Prasad Shrivastava. Dated 18th January, 1947.
 Captain Francis Chandra Das. Dated 21st January, 1947.
 Captain Man Singh. Dated 21st January, 1947.
 Captain T. S. R. Murti. Dated 25th January, 1947.
 Captain Gopala Krishna Iyer Ramachandran. Dated 26th January, 1947.
 Captain Hemanta Kumar Ray. Dated 28th January, 1947.
 Bhasker Rao Karnad. Dated 28th January, 1947.
 Captain N. Chandrasekharan. Dated 29th January, 1947.
 Captain Salem Ramakrishnan Sarvothaman. Dated 30th January, 1947.
 Captain Himangshu Jyoti Kar. Dated 1st February, 1947.
 Captain Pramod Kumar Pannalal Trivedi. Dated 1st February, 1947.
 Captain Sukhdev Bhatia. Dated 2nd February, 1947.
 Captain Mahmood Ali Khan. Dated 4th February, 1947.
 Captain Varaguna Kulasekara Pandyan. Dated 4th February, 1947.
 Captain Parayil Madhavan. Dated 5th February, 1947.
 Captain Phanindra Nath Ray Chaudhuri. Dated 5th February, 1947.
 Captain Man Mohan Singh. Dated 6th February, 1947.

8th February, 1947

Captain M. A. Narayana Iyengar.
 Captain Alexander Kaniantharai Thomas.
 Captain Riaz-Ud-Din Quraishy.
 Captain Hafiz-ur-Rahman.
 Captain K. N. S. Nair.
 Captain Kurichety Somayya.
 Captain Krishna Kali Bose. Dated 9th February, 1947.

11th February, 1947

Captain Bagh Singh Dhillon.
 Captain Jatindra Kumar Roy.
 Captain Jamshed Bakht.
 Captain Sudhamay Bhattacharyya.
 Captain Sardar Ahmed. Dated 13th February, 1947.
 Captain T. R. Seshadri. Dated 14th February, 1947.
 Captain Ghulam Mohy-ud-Din. Dated 15th February, 1947.

16th February, 1947

Captain Hari Chand.
 Captain Bhattachandra Vinayak Shiroikar.

Captain Basant Krishan Vaid.
 Captain Abdul Hakim Klokhar. Dated 17th February, 1947.
 Captain Autar Singh Bhasin. Dated 17th February, 1947.
 Captain Daya Shanker Kaichker. Dated 17th February, 1947.
 Captain Dady Framji Vachha. Dated 20th February, 1947.
 Captain Om Prakash. Dated 20th February, 1947.

22nd February, 1947

Captain Nirmal Kumar Sen.
 Captain Shuja-Ud-Din Butt.
 Captain Haneef Ahmad Ansari. Dated 23rd February, 1947.
 Captain Abdus Samad. Dated 24th February, 1947.
 Captain Padma Nava Bose. Dated 24th February, 1947.
 Captain Nripendra Nath Das. Dated 25th February, 1947.

26th February, 1947

Captain Asoka Kumar Bose.
 Captain Kalyan Kumar Dhar.
 Captain Diptiman Bose.
 Captain Gurbaksh Singh Grewal.
 Captain Jayanty Krishnamurty.
 Captain Mohd. Shafqat Ali Wasty.
 Captain Gurpur Narasimha Prabhu. Dated 28th February, 1947.
 Captain Sudhireswar Banerjee. Dated 1st March, 1947.
 Captain Victor Selvaraj. Dated 2nd March, 1947.
 Captain Ram Kumar Saksena. Dated 4th March, 1947.
 Captain Prithpal Singh. Dated 4th March, 1947.
 Captain Chidambra Manikka Muthu. Dated 5th March, 1947.
 Captain Girijakanta Chakravarty. Dated 6th March, 1947.
 Captain Altaf Husain. Dated 7th March, 1947.
 Captain Shivaram Vishwanath Tilak. Dated 7th March, 1947.

11th March, 1947

Captain Sukomal Sen.
 Captain Harmand Singh Dhillon.
 Captain Narayan Chandra Bhowal.
 Captain Homi Framji Daroga. Dated 14th March, 1947.
 Captain Edgar Joseph D'Netto. Dated 16th March, 1947.
 Captain Thomas Harcourt Emmanuel Henry Gnanaiya. Dated 14th March, 1947.
 Captain Kshitindra Nath Sen Gupta. Dated 16th March, 1947.
 Captain Tara Singh Grewal. Dated 18th March, 1947.
 Captain Sachindra Kumar Bhattacharya. Dated 19th March, 1947.
 Captain Khurshed Nussarwanji Gubbar. Dated 20th March, 1947.
 Captain Hrishikesh Dutt. Dated 21st March, 1947.
 Captain Dwarka Das Singhi. Dated 24th March, 1947.
 Captain Laxmi Narayan. Dated 26th March, 1947.
 Captain Pandit Ramanjulu Naidu. Dated 29th March, 1947.
 Captain Raghuvesh Prasad. Dated 29th March, 1947.
 Aetg. Major Cherukat Padmanabhan Nair. Dated 31st March, 1947.
 Captain Mario De-Menezes. Dated 4th April, 1947.
 Captain Abdul Walid Fazlur Rahman. Dated 8th April, 1947.
 Captain Govind Shamrao Vingle. Dated 8th April, 1947.
 Captain Dharendra Nath Bhattacharya. Dated 9th April, 1947.
 Captain Niranjan Sen Gupta. Dated 9th April, 1947.

Captain Jagadish Narain Sinha. Dated 12th April, 1947.
 Captain Susil Kumar Neogy. Dated 18th April, 1947.
 Captain Sudhansu Kumar Mitra. Dated 16th May, 1947.

(WITHIN INDIAN LIMITS)

Captain B. Singh. Dated 13th November, 1946.
 Captain B. A. Sreenivasa Iyengar. Dated 17th February, 1947.

(WOMEN'S BRANCH)

Captain (Miss) Margaret Therese D'Silva. Dated 7th June, 1946.
 Captain (Miss) Shireen Ardesbir Lal. Dated 14th August, 1946.
 Captain (Miss) Catherine Beemer. Dated 19th August, 1946.
 Captain (Miss) Mary Thomas. Dated 19th October, 1946.
 Captain (Mrs.) K. Pasricha (nee Irani). Dated 16th December, 1946.
 Captain (Miss) Lourda D'Cunha. Dated 17th December, 1946.
 Captain (Miss) Tanjore Vaidyanathan Sitalakshmi. Dated 14th January, 1947.
 Captain (Miss) Nivedita Sen. Dated 18th January, 1947.
 Captain (Miss) Charlotte Depuadros. Dated 5th February, 1947.

Publishers' Notice

SCIENTIFIC Articles and Notes of interest to the profession in India are solicited. Contributors of Original Articles are entitled to receive 25 reprints *gratis*; additional reprints can be obtained on payment. No reprints will be supplied unless contributors ask for them at the time of submitting their manuscripts.

The preparation of reprints entails rearranging the type, so that there is often a delay of a month or more, after the publication of the *Gazette*, before the reprints are ready. If reprints are not received within two months of publication of the *Gazette*, contributors should write to the Publishers.

Papers and articles forwarded for publication are understood to be offered to *The Indian Medical Gazette* alone, and any breach of this rule will be followed by non-publication. When any such article appears in *The Indian Medical Gazette*, the copyright automatically becomes the joint property of the author or authors and of the publishers.

Communications on Editorial Matters, Articles, Letters and Books for Review should be addressed to THE EDITOR, *The Indian Medical Gazette*, c/o The Calcutta School of Tropical Medicine, Central Avenue, Calcutta.

Communications for the Publishers relating to Subscriptions and Advertisements should be addressed to THE PUBLISHERS, *The Indian Medical Gazette*, P. O. Box No. 54, Calcutta.

Annual Subscription to 'The Indian Medical Gazette', Rs. 16 including postage, in India. Rs. 19-8 including postage, abroad. Single copies Re. 1-8 each. Back numbers (if available) for the previous year Rs. 2-8 each, and all other back numbers Rs. 5 each.

The Editors of *The Indian Medical Gazette* cannot advise correspondents with regard to prescriptions, diagnosis, etc., nor can they recommend individual practitioners by name, as any such action would constitute a breach of professional etiquette.

TREATMENT OF AMOEBIC LIVER ABSCESS WITH SECONDARY INFECTION

By R. N. CHAUDHURI, M.B., M.R.C.P. (Edin.),
T.D.D. (Wales)

Professor of Tropical Medicine
and

H. CHAKRAVARTI, M.B. (Cal.)

Assistant Research Worker

(From the Department of Tropical Medicine, School of
Tropical Medicine, Calcutta)

THE recognized treatment of amoebic liver abscess is a full course of emetine hydrochloride in single daily doses combined with closed aspiration of the cavity, which is repeated as required. The total dose of emetine in one course should not usually exceed 1 grain per stone body weight. Such conservative treatment is attended by a very low mortality rate and a considerable short period of disability. When, however, the abscess is secondarily infected with bacteria of various types open operation is regarded as the only treatment that is likely to do any good (Napier, 1943). But the results have been unsatisfactory and associated with a high mortality in practically all hands even in recent years. For instance, Berne (1942) treated 26 patients with open drainage, and 14 of them died. Ochsner and DeBakey (1943) reported a mortality of 3.6 per cent in a series of 83 cases in which emetine with or without aspiration was employed and a mortality of 22.1 per cent when open drainage was performed. Recently we had a case of amoebic liver abscess with secondary infection operated on, and he died.

In view of the high fatality rates associated with open drainage, there had been attempts to treat infected liver abscess cases with aspiration combined with sulphonamide or penicillin therapy. Alport and Ghalioungui (1939) reported a case of amoebic liver abscess, secondarily infected with *B. pyocyaneus*, in which recovery followed repeated aspirations and the local and systemic use of sulphonamide compounds. Noth and Hirshfeld (1944) reported a case of infected amoebic liver abscess treated successfully with aspiration and local instillation of penicillin. In view of these observations the following case is reported, the chief point of interest being the use of penicillin systemically as well as locally into the cavity of liver abscess secondarily infected with anaerobic streptococci.

Case report

The patient, a Hindu male, aged 32 years, was admitted to the Carmichael Hospital for

Tropical Diseases on the 17th June, 1946, for pain in the right side of the chest and abdomen with fever of seven weeks' duration. Prior to admission, the diagnosis of amoebic liver abscess had been made and he was given 15 injections of emetine, 1 grain each and was aspirated twice, about half a pint of chocolate coloured pus having been drawn on each occasion. He had suffered from dysentery a year ago and was treated with emetine at the time. On admission, he was very ill, toxic, running an irregular temperature with rapid pulse, and having night sweats. The liver was found enlarged from the right third intercostal space to two and a half inches below the costal margin and was very tender. The base of the right lung was dull on percussion, while auscultation revealed much diminished breath sounds and râles. Fluoroscopic examination showed the right dome of the diaphragm considerably raised and fixed. The white cell count was 16,000 per c.mm. with 81 per cent polymorphonuclear cells. Total plasma proteins was 9.2 grammes (albumin 3.3 grammes and globulin 5.9 grammes) per 100 c.c. The urine was clear; no ova or protozoa were found in stools. An exploratory puncture showed chocolate coloured pus with a faecal foul smell. The smear showed numerous pus cells and streptococci but the culture was sterile. A later culture of the pus under anaerobic conditions revealed streptococci. No *E. histolytica* was found.

In view of the previous experience and in consultation with Major Andreassen we decided to avoid open drainage in this patient and instituted penicillin therapy to combat the secondary infection along with aspiration.

In the first aspiration about one pint of pus was withdrawn and 50,000 units of penicillin in 20 c.c. of normal saline were introduced locally in the cavity. Some air was also injected at the same time and a skiagram of the liver was taken, which showed a fairly big abscess cavity with a fluid level (unfortunately the skiagram was lost). After this aspiration there was some amelioration of the local symptoms and the liver became smaller but the fever persisted. After three days the size of the liver and the local tenderness somewhat increased apparently due to further accumulation of pus in the cavity. He was then given penicillin injections, 20,000 units three hourly for seven days, and the cavity was aspirated repeatedly on alternate days at first and later at an interval of several days, being guided by the rise of temperature and local tenderness. Penicillin (50,000 units) was injected into the abscess cavity after each aspiration. During a period of five weeks he was aspirated ten times and six pints of pus were withdrawn. Thereafter the patient became gradually afebrile and his appetite improved. The white cell count gradually came down, and the serum albumin level increased while globulin decreased (see table).

Table showing leucocyte counts and plasma proteins

Date	W.B.C. c.mm. (in 1,000)	Polymorpho- nuclear cell (%)	PLASMA PROTEINS (GRAMMES %)		
			Total	Albumin	Globulin
18-6-46	16.0	81	9.2	3.3	5.9
2-7-46	11.5	76	8.9	3.8	5.1
19-7-46	13.0	68	7.5	3.45	4.05
6-8-46	10.5	64	7.9	3.95	3.95
16-8-46	8.0	65	7.5	3.9	3.6

The general condition of the patient steadily improved and he gained 8 pounds in weight. There was no more rise of temperature, no sweating, and though the liver could be just palpated, there was no tenderness. A fluoroscopic examination showed absence of any upward enlargement and the movement of the diaphragm was fairly good. During convalescence he complained of a slight catchy pain and discomfort in the right iliac fossa. The cæcum and ascending colon which could now be palpated with ease were slightly thickened and definitely tender; so he was given a course of six 1 grain emetine injections along with enterovioform by mouth with relief of these symptoms. He was discharged from the hospital on 21st August and was followed up as an out-patient for a month, and during that period he kept very well indeed and gained 5 pounds more.

Discussion

Clinically and radiologically this was a typical case of amoebic liver abscess. The faecal odour of the pus was due to secondary infection with anaerobic streptococci. Invasion of the liver might have occurred by portal infection, by direct spread from the adjacent structure, by blood-borne infection or by aspirations done outside before admission. The patient was seriously ill, and the general outlook seemed bad from the standpoint of therapy and prognosis. Considering the high fatality rate usually associated with surgical drainage mainly because of the unavoidable post-operative bacterial invasion of the abscess, and the value of the local penicillin therapy in such cases, it was decided to treat this patient by repeated aspiration combined with injection of penicillin locally and systemically. The result was so successful in this case that this method of treatment is recommended before considering open drainage in secondarily infected amoebic abscess of the liver.

Our grateful thanks are due to Major Andreasen, I.M.S., Professor of Surgery, Medical College, Calcutta, for valuable suggestions.

A NEW TREATMENT OF SCABIES

By D. N. ROY

and

S. M. GHOSH

(From the Department of Medical Entomology, School of Tropical Medicine, Calcutta)

WHEN it was discovered that a synthetic preparation which has been given the trade name phenyl cellosolve possessed marked sarcopticidal properties, the outcome was a natural desire to use it for the treatment of scabies, but before this was done it became necessary to determine any harmful side effects it might produce when applied to the skin of man.

Phenyl cellosolve* (monophenyl ether of ethylene glycol) is a liquid preparation, with an aromatic odour and has a bitter taste producing no tingling sensation of the tongue. It is mainly used as a solvent in industry. It is freely miscible with absolute alcohol and vegetable oil but not with mineral oil, e.g. liquid paraffin and kerosene oil. The oily mixture does not excite any appreciable irritation or burning when applied to a scratched or abraded skin. It is also well tolerated by babies and children. The oily mixture is innocuous to the eyes. It does not produce any ill effect when applied externally even over the whole body for days together.

Except for the treatment of pediculosis, it has not yet been employed for any other medical purposes. It can readily kill not only the adult louse but also the egg (Davis *et al.*, 1944; Hansens, 1945; Roy and Ghosh, 1947). When used for this purpose it is prepared with alcohol as follows :—

Phenyl cellosolve ..	5 per cent
Absolute alcohol ..	37.5 per cent
Water ..	57.5 per cent

When prepared with ground-nut oil it acts on the post-embryonic stages only and not on the eggs.

For the purpose of evaluating its action on *Sarcoptes scabiei* of man, the following methods were employed :

* We are particularly grateful to Messrs. Carbide and Carbon Chemical Corporation, manufacturers of synthetic organic chemicals, 30, East Forty-Second Street, New York 17, N.Y., U.S.A., for supplying us, free of charge, with a generous quantity of phenyl cellosolve.

(a) A minute drop of the oily mixture in groundnut oil was put on the freshly extracted mite placed on a glass slide and the excess of oil wiped off from its body with filter paper.

(b) The mite was released from the point of a needle on to the dorsum of the hand previously smeared very lightly with the oil. The mite was next removed to a glass slide as quickly as possible.

Only when all activities ceased, the mite was regarded as dead.

The results of tests carried out in the way stated above are shown below :

	Strength of the oily mixture	Duration of contact	Interval till death
Tests performed on glass slide.	5 per cent	15 seconds	12-18 minutes
	10 "	5-10 seconds	2-3 "
	15 "	5-10 "	Less than 1 minute.
Tests performed on hand.	10 "	15-30 "	1 minute
	10 "	1 minute	Immediate
	15 "	15-30 seconds	"

It will thus be evident that for destroying the mite on the body all that is necessary is to establish contact between the mite and the oily mixture (either 10 or 15 per cent) for a few seconds only. As a preliminary to this the burrows have to be opened and the mite exposed to the action of phenyl cellosolve and this is best done by scrubbing with soap and hot water while taking a bath.

Laboratory tests also reveal that for practical purposes the 10 per cent mixture can be regarded as efficient as the 15 per cent. We have therefore used the former in the treatment of all our cases.

This preliminary report includes the treatment of 35 cases of scabies amongst Indians only. Some of them were chronic cases suffering for more than a year. Many had thickened skin on the hands, axillary folds and inner surface of the thighs. Quite a large proportion of the patients treated had impetigo. The lowest age was 6 months. This was regarded as a particularly severe case. The highest age was 70 and the case had also a very severe type of the disease.

The following procedure for its use has been applied :

(a) Whenever possible a bath with soap and hot water was advised in the morning. Sometimes only sponging was done. Some outside patients had a very poor bath and did not take bath regularly.

(b) After drying the body, the oil was applied by means of cotton-wool over the entire body or over the affected parts only.

(c) Septic ulcers were cleaned and treated with the oil.

Only a little oil should be used as a thick application is not only unnecessary but also wasteful.

(d) The oil is applied again at night before going to bed and at any other time whenever there is itching. Scratching will cause the burrows to become exposed.

The oily preparation is quite stable and it is not necessary to prepare it fresh every time before use.

The details of treatment with the oily mixture of phenyl cellosolve will be published later when more clinical material has been obtained.

Phenyl cellosolve is marketed at a cost of \$0.76 per pound, f.a.s. New York. The cheapest vegetable oil available may be used for preparing the mixture.

EARLY DIAGNOSIS OF TSUTSUGAMUSHI*

By NAJIB KHAN, M.D. (Dunelm)
LIEUTENANT-COLONEL

Physician Incharge, Tata Main Hospital, Jamshedpur,
Late Officer Incharge of the Medical Division of a
General Hospital, Late of R.A.M.C.

EARLY diagnosis of tsutsugamushi (OXK typhus) often offers a serious problem to the clinician. The difficulty mainly arises in sporadic cases which are seen from time to time and in the first cases in an epidemic. This is because, firstly, no definite early clinical features of this disease have been described and, secondly, there is usually a striking general resemblance between tsutsugamushi and fevers of the dengue group as well as malaria. Of a series of 135 cases admitted to our hospital over 62 per cent had been diagnosed and treated as malaria for first 3 to 5 days before admission.

Most writers on scrub typhus emphasize that the diagnosis should be based on eschar, rash, adenopathy and Weil-Felix test. But a study of the table reveals that these symptoms may not be present according to some observers while their incidence according to others may vary greatly over a wide range.

Agglutination to OXK proteus strain in dilutions of 1 in 320 is considered by Stitt, Clough and Clough (1938) to be 'usually but not invariably diagnostic'. However, Megaw (1945) in his recent article on scrub typhus writes that 'occasionally reaction does not become positive till convalescence has set in. In patients who die

* Being a paper read at the Medical Section of the 34th Session of the Indian Science Congress.

Eu = Europeans.

I = Indians.

before the 4th day the reaction often remains negative till death, otherwise it becomes positive in a very high proportion of cases'. In Davidas's series a titre of 1 to 160 was reached on the 10th day; in Tattersall's (1945) series 80 per cent of the cases gave OXK agglutination of 1 in 200 between 11th and 13th day of illness; in Menon's (1945) cases the titre of OXK agglutination on the 17th day of illness was 1 in 250 and in my series a titre of 250 of OXK proteus was reached between the 11th and 22nd day of illness. The highest titre was reached on the 22nd and 28th days. Thus if the diagnosis of scrub typhus is to be based on Weil-Felix test, in most of the cases it will be in the state of convalescence that the diagnosis will be made.

Early diagnosis of tsutsugamushi is not only important from the epidemiological point of view, but also from the viewpoint of the patient who should not be moved after the 5th day. Thus the question arises: On what is the diagnosis of scrub typhus to be based? The clinical aspect of the case often presents some important signs and symptoms which can prove to be helpful to the physician in the early diagnosis. These are outlined below and were noticed in practically all my cases but the observation of these points was not the only criterion of the diagnosis; careful records were also kept and the diagnosis finally checked by the OXK titre rising and eventually being over 1 to 250.

1. *Headache*.—It was complained of by all the patients. It is frontal in type, severe, intractable and unrelieved by aspirin or other analgesics. The character of the headache is typical and is often described by patients as 'boring' or 'piercing', which 'moves from one temple to the other and back again'.

2. *Asthenia*.—This is out of proportion to the physical signs and the duration of the illness and is seen from the very beginning. The patients themselves feel the sudden loss of energy so much that talking is a severe exertion to them.

3. *Lethargy and apathy*.—They are a constant feature of the disease. After recovery some of the intelligent patients described their state during their illness as not wishing to be disturbed or make any effort but sink in the bed, no matter how uncomfortable, and take no interest in the surroundings no matter how annoying or dirty.

4. *Delayed reaction time*.—It is another feature of scrub typhus. Even simple questions are understood by the patient very much more slowly than normally. Patient is usually fully conscious, but understanding is slow. This fact is often attributed to deafness, but talking to patients after their recovery has elicited that they heard but took a long time to understand.

5. *Vacant expression*.—It was found in all the patients. This expression with fully sensible mentality is always striking.

6. *Eyes* have a peculiar state and that is accentuated by unwillingness on the part of the patient to move his eyes. When the patient is asked to look towards the side, he will rather move his head than the eyes. After recovery the patients often said that they were tired of looking at the objects opposite to them in their beds, but they could not move their eyes and the only way to avoid looking on the monotonous objects, like the face of the patient on the bed opposite to them, was to shut their eyes.

7. *Deafness* of the nerve type was present in more than half of our cases and in 35 per cent of Tattersall's cases.

8. The combination of asthenia, lethargy, apathy and increased reaction time presents a typical picture of the patient who lies in the bed with half closed eyes and takes no interest in the surroundings and is loath to make any movements. At one time when a great number of patients were being admitted to the hospital and we were on the look out for scrub typhus it was found that if a patient with fever who was suspected of scrub typhus was asked to sit up, and he did sit up, he was found not to be a case of scrub typhus. This rough

test was found reliable time and time again as checked by other observations and investigations.

9. *Hypopiesis* was a significant fact in all our cases and evident fairly early in the disease. In the Europeans the systolic blood pressure was between 100 and 115 mm. of mercury and in the Indians between 90 and 105 mm. of mercury. This low blood pressure persisted for a considerable time after recovery. This is not to be wondered at when we know that Davidas found in 9 of his 15 post mortems of scrub typhus severe myocarditis while the other six had similar affection of the heart, but less severe.

10. *Fundal changes* were seen in over two-thirds of our cases. The usual picture was papillitis, but in some optic neuritis was seen. Papillitis was of $\frac{1}{2}$ to 1 D. In some of the cases acute retinitis was also present. Major Y. K. C. Pundit reports that a rare phenomenon is uveitis. In this condition the muscae volitantes caused by mild degeneration of the vitreous persists for a long time. In some cases after the fever had subsided and the patient was well enough to sit up Captain T. Donogon, the Ophthalmologist, found central scotoma. This seems to clear up after complete convalescence. Therefore examination of the fundus oculi is often helpful in the diagnosis.

11. *Blood picture*.—The total white cell count gives no help in the diagnosis, but the blood picture is often helpful. There are usually present 'peculiar' non-granular cells. These cells could not be classified in any known type, but appear to be a cross between lymphocytes and monocytes. They appear fairly early in the disease and were present in most of our cases. They were found to be 15 to 50 per cent in different cases. In some cases these 'peculiar' cells mislead to the diagnosis of infective mononucleosis.

12. Early morning remissions of fever were seen in the 4-hourly charts in all our cases. The fever comes down 3 to 5 degrees between the hours of 2 a.m. and 6 a.m. without there being any great alteration in the pulse rate.

These twelve points, if carefully observed, help the clinician to come to an early diagnosis in case of tsutsugamushi.

Summary

The difficulties in the early diagnosis of scrub typhus are emphasized but certain signs and symptoms, viz, headache, lethargy and apathy; vacant expression; stare of the eyes; deafness of the nerve type; hypopiesis, fundal changes and blood picture and early morning remissions are helpful.

LEUCOCYTES IN NORMAL RHESUS MONKEYS

By S. LAL KALRA

Field Typhus Research Det., Jalahalli

DURING a study of experimental measles in rhesus monkeys the available literature was consulted for the normal figures of total and differential white cell counts in these animals. It was found that the results reported by 11 different authors (table I) varied within a wide range. The differential count was always mentioned in percentages which either gives no idea of the absolute numbers, or can even present a wrong picture. In table III with a percentage of 43.8 the total number of lymphocytes is 7,670, and with a higher percentage of 52.7 the total number is actually reduced to 6,352.

The present study was undertaken to find out the reason for these vastly different results reported by various authors. Twenty-two animals were examined daily for 4 to 12 days until a steady level was obtained. All the animals were apparently healthy, considering their daily temperature, body weight, activity, appetite and stools.

The counts were made at the same time daily before feeding. The animal was caught without being much excited and the blood was drawn when it was calm. Freely flowing blood was drawn from a razor blade cut over the marginal ear vein directly into a pipette. Smears made by the coverslip method were stained with Wright's stain. Two hundred cells were counted, from each smear, but if unusual results were noted, an additional 200 cells were counted. Our data are appended at the end in table I.

Total white cells.—These were found to vary from 10,650 to 29,400; average 18,490, standard deviation 5,200. The animals running high counts between 20,000 and 30,000 had proportionately greater daily fluctuations, while those between 10,000 and 14,000 showed a steadier level. When some of the counts were arranged in order of magnitude of the mean value, the standard deviation of these means increased with the value of the mean, but the coefficient of variation remained more or less the same (table II). It indicated a greater scatter in the daily counts of the former series, which

raised the mean value. In spite of these fluctuations, which were due to some unrecognized external or internal stimuli, the animals were apparently healthy. But the significant fact was that these fluctuations affected mainly the neutrophils. A similar observation has been made on kittens by Hammon (1940).

In table III, the total leucocytes are grouped according to magnitude in four categories. The

leucocyte count, an increase or decrease in neutrophils being entirely responsible for this change. It explained the divergent figures for these cells reported by different workers as shown in table I.

Conclusions

In any experiment on monkeys little importance can be attached to a change or daily

* Modified from Scarborough (1931).

TABLE II

Total mean count	Standard deviation	Coefficient of variation	Total mean count	Standard deviation	Coefficient of variation
10,650	1,640	15.0	22,000	2,940	13.1
10,700	1,460	13.6	22,940	3,390	14.8
12,200	1,440	11.8	27,000	2,560	9.4
12,600	1,330	12.5	29,300	4,130	15.0
14,280	1,820	12.7	29,400	2,160	7.3

TABLE III

Number of counts	..	51	43	24	17
Limits	9,000-15,000	15,000-20,000	20,000-25,000	25,000-30,000
Average total leucocytes	12,040	17,500	22,320	28,630
Neutrophils, per cent	43.2	53.0	62.4	71.2
Lymphocytes, per cent	52.7	43.8	34.9	25.4
Total neutrophils	5,203	9,287	13,941	20,384
Total lymphocytes	6,352	7,670	7,807	7,272

neutrophils showed an increase in the percentage and total number relative to the rise in the total leucocytes. The lymphocytes showed a fall in the percentage with the rise of total cell count, but their total number was fairly constant. The standard deviation and coefficient of variation for the neutrophils were 5,200 and 48.05 respectively, and for the lymphocytes 1,500 and 21.4. These figures, again, indicated that lymphocytes remained relatively constant and fluctuated less than the neutrophils. Moreover in a monkey running a low leucocyte count the lymphocytes were higher in percentage and total number than neutrophils, with the reverse picture in an animal with a high

fluctuation in the total leucocyte count and neutrophils unless the character of the base line has been studied before the experiment, while a change in the lymphocytes is always significant.

The lymphocytes in the series varied between the extreme limits of 4,100 and 13,450; average 7,100; 79 per cent of the counts were within a range of 4,000 to 9,000. A fairly constant level was maintained in a particular animal and a change could be considered of pathological significance.

The limits for neutrophils were from 2,540 to 21,000, average 10,820; only 67.4 per cent of the counts were within a range of 3,000 to 12,000. Marked daily fluctuations were present

in some apparently healthy animals without any recognizable cause.

SEROLOGICAL TECHNIQUE (contd.)

By S. D. S. GREVAL

LIEUTENANT-COLONEL, late I.M.S.

(From the Laboratory of the Imperial Serologist and Chemical Examiner to the Government of India, School of Tropical Medicine, Calcutta)

Dilutions of complement containing required MHD of complement.—If the titre, as given in the example, is 1 in 60, then a 1 in 60 dilution contains 1 MHD. Two MHD will be contained in a 2 in 60 or 1 in 30 dilution. Similarly, 3 MHD, 4 MHD and 5 MHD will be contained in 3 in 60 ($= 1$ in 20), 4 in 60 ($= 1$ in 15) and 5 in 60 ($= 1$ in 12) respectively.

The restriction in the quantity of the complement used in the reaction is effected by restricting the MHD in the dilution used.

DETAILS OF LECITHIN COMPLEMENT FIXATION (LCF) FOR SYPHILIS, COMMONLY CALLED WASSERMANN REACTION (WR)

Rows and Columns of Tubes in a Rack

The diagram gives the arrangement of the tubes in rows from left to right (illustrated by

the 2nd row in the diagram) and in columns from front backwards (illustrated by the 6th column in the diagram).

For titration of reagents metal racks like the one depicted are used while for the routine tests wooden racks carrying single rows of tubes may be used. The wooden racks are placed four deep to form columns like the metal racks.

The Antigens

The writer uses 4 antigens, namely, plain alcoholic liquid heart extract antigen, antigen from the same extract cholesterolized, the cholesterolized extract phenolized in dilution, and antigen from Bordet's extract cholesterolized.

The plain alcoholic liquid heart extract.—Ten grammes of human heart muscle free from fat are ground up into paste with clean sand and added to 100 c.c. of absolute alcohol in a wide mouthed bottle. The bottle is stoppered, shaken vigorously and left in a cupboard for 24 hours. Next day the extract after another vigorous shaking is filtered into a narrow mouthed reagent bottle. (The funnel carrying the filter paper is covered with a Petri dish.) The filtrate is the extract. When several extracts are prepared (and stored in a cupboard) they are tested together for suitability concerning: (1) *Turbidity.* A 1 in 15 dilution in normal saline should be obviously turbid or at least as turbid as the one made from a satisfactory extract in use. For making the dilution a measured quantity of the extract is put into one tube and the required quantity of saline into another. The saline is poured into the extract, shaken and the mixture poured into the 2nd and back into the 1st tube. The dilution is the antigen. (2) *Hemolytic power.* 3 volumes

Rows and Columns of Tubes in a Rack.

of the dilution are left in contact with 1 volume of sensitized and standardized sheep rbc (dilution 0.75 c.c. + rbc 0.25 c.c.) at 37°C. for half an hour. There should be no trace of hæmolysis. The tube is left overnight at ice box temperature and examined next morning when the rbc have settled down. The hæmolysis occurs only occasionally. Excess of antigen is used to make certain of the hæmolysis. (3) *Anticomplementary power*. 1 volume added to 1 volume of complement dilution containing 1 MHD should not depress the hæmolytic power of the complement (complement dilution 0.25 c.c. + normal saline 0.25 c.c. . . . incubated . . . + sensitized rbc 0.25 c.c. . . . incubated = complete hæmolysis). (4) *Complement fixing power*. The dilutions are put up with a pooled serum from 6 cases (also see *the known positive serum*) of untreated florid secondary syphilis, diluted 1 in 10, 1 in 25 and 1 in 50 and 4 MHD of complement, as shown in the TABLE OF TITRATION OF HEART EXTRACT.

of hæmolysis, due to the serum being anticomplementary, in this tube.) After the mixtures have been left at room temperature for half an hour and in the incubator for half an hour the sensitized rbc suspension is added and the tubes reincubated. Negative (—) and doubtful (±) reactions are read the same day while positive reaction (+) and traces of hæmolysis (T) are read the next day. Serum control must be —. 1st row in all columns must be +, 2nd row in all columns must be T, 3rd row in all columns must be — or ?— (almost negative, tube of full colour and without coloured deposit next day). The extracts giving the required fixation are selected for pooling. A fixation lower than the one given by the extract already in use is never accepted. At least six extracts should be pooled to provide the antigen.

The extracts giving higher fixation are also selected but kept aside (for mixing with weaker extracts). Such extracts are met with occasionally only.

TABLE OF TITRATION OF HEART EXTRACT

Column number	I	II	III	IV	
(Rows of tubes, running like this \rightarrow , are grouped into columns, running like this \downarrow , see sketch.)	From front backwards \downarrow containing: comp. dil. 4 MHD per vol. 1 vol., and 1 vol. of 1 in 15 dil. in saline of				
	heart ext. 1	heart ext. 2	heart ext. 3	heart ext. 4	
Third row, from left to right \rightarrow . For serum dil., 1 vol. of 1 in :	50	50	50	50	
Second row, from left to right \rightarrow . For serum dil., 1 vol. of 1 in :	25	25	25	25	
First row, from left to right \rightarrow . For serum dil., 1 vol. of 1 in :	10	10	10	10	
					An extra tube (serum control) for :— — Serum dil., 1 in 10, 1 vol. — Comp., 2 MHD per vol. 1 vol. — Saline 1 vol.

For 4 extracts 13 tubes are required: four columns from front backwards, 3 rows from side to side and 1 extra tube (see TABLE OF TITRATION OF HEART EXTRACT).

Into each column is put dilution from a different extract.

More columns are added for more extracts. A suitable extract already in use is always included for comparison. Each column has the same extract. Each row has the same dilution of serum. The extra tube is the serum control for the whole rack. (There should be no inhibition

The extracts giving lower fixation are corrected by concentration. A 1 in 10 dilution in saline (instead of 1 in 15) is tested for hæmolytic power, anticomplementary power and complement fixing power. If it comes up to the standard 15 c.c. of the alcoholic extract are evaporated to 10 c.c. An intermediate concentration (15 c.c. evaporated to 12½ c.c.) or mixing with a strong extract (kept aside for the purpose) may suffice for some extracts. Weak extracts are frequently found. An extract which cannot be corrected (does not improve

Bordet's antigen.—(1) One hundred grammes of human heart muscle cut into pieces (not minced) are left in contact with 125 c.c. of absolute alcohol for a week. (2) The alcohol is poured off and the muscle dried in an incubator for several days (should be like pieces of wood). (3) The dried muscle is left in 200 c.c. of acetone for a week. (4) The acetone is

Titration of the complement in the presence of antigens.—The complement is titrated in the presence of (a) antigen 1, from plain alcoholic cholesterolized extract; (b) antigen 3, the same dilution prepared with phenolized saline; and (c) antigen 4, dilution of cholesterolized Bordet's extract, as shown in the TABLE OF TITRATION OF THE COMPLEMENT IN THE PRESENCE OF ANTIGENS, in a slightly different order.

Column number	I	II	III	IV	V	VI	VII	VIII
(Rows of tubes, running like this →, are grouped into columns running like this ↓.)	For complement dilutions of 1 in:—							
	20	30	40	50	60	70	80	90

Ant. 1 1 vol.
Saline 1 vol.

1st and 3rd rows have only 1 volume of complement while 2nd and 4th rows have 2 volumes.

1st row will give the titre of the complement acting alone while 2nd, 3rd and 4th rows give the titre when the complement is acting in the presence of the antigens. Antigen 2 is not used in the titration.

All tubes have up to this stage three volumes of total fluid (conveniently a volume = 0.25 c.c.).

The tubes are left at room temperature $\frac{1}{2}$ hour and in the incubator $\frac{1}{2}$ hour. 1 volume of sensitized rbe is then added and the tubes re-incubated for $\frac{1}{2}$ hour. In the 1st row the last crystal clear and ruby red tube from the left gives the MHD of the complement when acting alone, while in the other rows a tube *just falling short* of this clarity and redness will give the MHD when the complement is acting in the presence of antigen.

Qualitative and quantitative differences in complement.—Ideally and typically the 1st row should give the MHD in 1 in 40, 1 in 50 and 1 in 60 dilutions of complement. This is the *optimal titre*. A titre below 1 in 40 is *low* while that above 1 in 60 is *high*.

The 3rd row (with Bordet's cholesterolized antigen, Ant. 4) usually gives the same titre. Antigen 4 is not anticomplementary, that is why the volume of complement dilution in the 1st and 3rd rows is the same. When doubt arises as to whether the right or left of the two tubes in the 1st row should be taken for the MHD the one agreeing with the tube selected in this row should be preferred.

Again ideally and typically the 2nd row which contains *double* the quantity of complement contained in the 1st row (the antigen being anticomplementary to the extent of 1 MHD) should give the MHD in the same column as the 1st row. This is the *optimal reaction*. If the 2nd row lags behind, the complement is *cholesterol shy*. More than 2 MHD of it is needed for the complete lysis of rbe in the presence of the cholesterol contained in the antigen. If the 2nd row is ahead of the 1st, the complement is *cholesterol fast*. Less than 2 MHD of it is needed for the complete lysis of rbe in the presence of the antigen.

A combination of optimal titre and optimal reaction gives the best results in LCF (WR). If possible standardization of the heart extracts (by selection or correction) should be undertaken on a day when such a complement is available.

The reaction remaining optimal when the titre is high or low the fixation is excessive or poor respectively. Adjustment of the MHD is necessary in the test proper.

A cholesterol fast complement gives less fixation. Adjustment in the antigen-complement system is needed in the test proper.

A cholesterol shy complement gives more fixation. Another adjustment in the antigen-complement system is needed in the test proper.

Adjustments in the MHD. 1. *For complement of optimal reaction.*—(1) When the titre is high reduce the reading of MHD by 10 : for 1 in 90, 1 in 80 and 1 in 70 take 1 in 80, 1 in 70 and 1 in 60 respectively. The excess in fixation will be balanced by the excess in the MHD. (2) When the titre is low do not insist on a crystal clear and ruby red tube in the 1st row : one falling short of it will suffice. The corresponding tube in the 2nd row may be correspondingly imperfect.

2. *For cholesterol fast complement.*—(1) When the MHD in the 2nd row is ahead of that in the 1st row by a convenient fraction, reduce the MHD in the test proper by that fraction. Example one : 1st row tube in column 1 in 60 and 2nd row tube in column 1 in 90; the difference is $\frac{1}{2}$ of 60; work with 1 in 60 and reduce the 3 MHD and 5 MHD of the test proper (*vide infra*) to $2\frac{1}{2}$ MHD and $4\frac{1}{2}$ MHD. The deficiency in fixation will be balanced by the deficiency in the MHD. Example two : 1st row tube in column 1 in 40 and 2nd row tube in column 1 in 80 : the difference is equal to 40; work with 1 in 40 and reduce the 3 MHD and 5 MHD of the test proper to 2 MHD and 4 MHD. Intermediate figures may be taken, always erring on the side of having a slight excess of complement. (2) When the fraction is not convenient and the difference is not much, do not adjust. Example : 1st row tube in column 1 in 60 and 2nd row tube in column 1 in 70; work with 1 in 60. (3) When the fraction is not known and the titre is high, reduce 3 MHD and 5 MHD to 2 MHD and 4 MHD. Example one : 1st row tube in column 1 in 90, 2nd row tube all clear and the extra tube fully or almost fully haemolysed; work with 1 in 90 and reduce 3 MHD and 5 MHD to 2 MHD and 4 MHD. Example two : 1st row tube in column 1 in 80, 2nd row all clear and the extra tube fully or almost fully haemolysed; work with 1 in 80 and reduce as before. Example three : 1st row tube in column 1 in 70, 2nd row all clear and the extra tube substantially haemolysed; work with 1 in 70 and reduce as before. (4) When the titre is not high and none of the devices so far described fits in, attempt a fit along the lines of devices (1), (2) and (3) with phenolized antigen (no. 3) and use this antigen in the test.

The MHD is not adjusted for Bordet's antigen.

3. *For cholesterol shy complement.*—(1) When there is a lag of one or two tubes only, take that tube in the 1st row which corresponds to the clear tube in the 2nd row. Example : 1st row tube in column 1 in 60 and 2nd row tube in column 1 in 40; work with 1 in 40. The excess in fixation will be balanced by the excess in the MHD. The lag is usually confined to this limit. (2) When the 2nd row tubes follow the 1st row tubes but are less clear than usual, mix the cholesterolized extract two parts with uncholesterolized extract one part and dilute the mixture in the usual way. (3) When the 2nd row tubes are only half lysed, mix the

cholesterolized extract one part with uncholesterolized extract one part. (4) When the 2nd row tubes are hardly lysed but the 3rd row tubes, with Bordet's antigen, are lysed, mix the cholesterolized extract one part with uncholesterolized extract two parts. Antigen controls with 2 MHD of complement will be necessary for (2), (3) and (4). When even the 3rd row tubes are hardly lysed reject the complement.

RHEUMATIC DISEASES AND MOUTH INFECTION

By ARUN GANGULI, Z.D.S. (Vienna), F.D.I.

Visiting Dental Surgeon, Carmichael Medical College Hospitals, Calcutta

THE problem of focal infection in relation to rheumatic diseases has received too little critical consideration. The subject must be approached first from the standpoint of the nature of systemic diseases. In other words we have got to know what rheumatism and arthritis are.

The term 'rheumatic diseases' embraces a big group of various illnesses which have their chief characteristic pain in and around joints. 'Rheumatism' is not a disease but a generic term for many illnesses. These illnesses can be divided into two main divisions: (1) articular and (2) non-articular. In this paper I will discuss only rheumatoid arthritis and osteoarthritis which occur with about equal frequency, but they differ greatly in aetiology, clinical, pathological and therapeutic considerations.

Rheumatoid arthritis

It is a general progressive systemic disease, the chief manifestations being the articular changes. At the onset the patient usually complains of malaise, fatigue, poor appetite and loss of weight. Then several joints begin to ache and become increasingly painful, swollen, tender and sometimes red: when the finger joints are involved they become fusiform in shape as a result of the capsular swelling of the proximal interphalangeal joint. If unchecked great destruction and deformity result. The primary and characteristic pathologic change is inflammation of synovia which lines the capsule and of the fibrous capsule of the joint, and then secondary changes with destruction of the cartilage, atrophy of the bone, deformity, dislocations and ankylosis.

The cause of rheumatoid arthritis is unknown. The four most popular theories are: (1) infectious, (2) metabolic and nutritional, (3) neurogenic, and (4) endocrine. I will discuss the first theory here.

There is more evidence to support this theory than any other. In the first place many patients give history that the disease started shortly after infection. The laboratory

changes that accompany this disease, such as leukocytosis and increased sedimentation rate, support this infection theory. The theory of 'focal infection' started long ago, was popularized by F. B. Billings of U.S.A. and Priv. Dozent Stein of Vienna, and was warmly received because it suggested a reasonable approach to the disease. As years passed the enthusiasm gradually died down.

Attempts made to produce the disease in animals by the use of all sorts of organisms were not very encouraging. Arthritis has been produced repeatedly in animals by the injection of organisms removed from persons suffering from rheumatoid arthritis but it was unlike the characteristic inflammation in human beings. While working in the house staff at the focal infection department of the jaw department of the University Hospital, Vienna, under Professor Pichler and Priv. Dozent Stein (focal infection abtiefung der kiefer station der Universitat Zü Wien) I have witnessed many cases of arthritis in animals produced by sealing the organisms in teeth to stimulate a focus of infection, but at the same time I must confess that it was not the counterpart of rheumatoid arthritis in man. To prove that a focus of infection really causes arthritis we have got to find out whether the following evidence does exist: (1) a focus must always be found, (2) some substance, such as bacteria, host cell products of inflammation, must get from that focus to the infected parts, (3) the inflammation in the joints must be proved as a result of some specific substance that gets from a focus to the affected parts. But as these evidences cannot be obtained, the problem remains a theory. After all these one is naturally left without proof and with many questions as to whether focal infection accounts for this disease.

In spite of the above arguments my personal 'clinical impression' is that the patients benefited by the removal of infected teeth. I must hasten to add at the same time that the teeth should not be removed just because they are still in the head of the patient suffering from rheumatoid arthritis. This practice should never be encouraged. I advocate that abscessed teeth should be scarified and infected gums should be properly treated. This will also indirectly help the patient, as by such procedures the patient's general health may be improved and thereby his ability to combat the disease. I feel very strongly that rheumatoid arthritis results from alteration of host's tissue as a result of 'trigger mechanism' that in very many cases probably is localized infection at the roots of teeth, tonsils or elsewhere. Host tissue damaged by any such irritating illness may liberate antigenic substances which react with antibodies in joint synovia and capsule causing inflammation. Once initiated in this way, rheumatoid arthritis may continue, recur or become exacerbated without continuation or recurrence of the original trigger mechanism.

Case history

Miss S. C., age 22. Before the onset of the disease, the patient was very active, but gradually began to feel tired. Loss of appetite and weight. Pain in the spinal column joint and ultimately several joints began to ache and swell especially the fingers. General condition: irregular menstruation; pain and tenderness of the head; antrum and tonsils good.

Laboratory findings.—Increased sedimentation rate of the R.B.C., mild anæmia and leukocytosis.

Gums.—Healthy.

Teeth.—Upper right canine and first molar (right) filled with amalgam.

X-ray.—Examination of teeth revealed imperfect root canal treatment in both. An apical abscess in the molar and some degenerative changes in the apical portion of the canine.

Upper first molar was extracted. Old filling of the canine was removed, apicoectomy performed on it and the pulp canal was filled with silver point. The patient recovered amazingly in a very short period.

Case history

Mrs. S. D., age 38. The patient was overweight, a great pan-chewer (about 100 a day). She felt pain practically in all joints. History of low and intermittent fever, sub-maxillary glands swollen.

Laboratory findings.—Showed increased sedimentation rates of the red blood cells and leukocytosis.

Gums and teeth.—Gums extremely unhealthy, upper right and left first and second molar teeth loose, formation of gum boil on the palatal aspect, pus coming out on pressure, the entire area swollen and painful. My first duty was to extract gradually all the upper molars on both sides. It is to be noted that the patient was so bad that I was called at her house for extraction. One week after my last visit the patient was brought to my office. I found her definitely better, the rest of the gums were treated in the routine manner. Vitamins B and C were prescribed in an intensive dosage. Four weeks after the patient was as normal as most of us.

Osteo-arthritis

It is a degenerative condition of middle age and old age which affects the articular cartilages and weight-bearing surfaces of the larger joints, such as knee and hips and articulations of spinal column. The pathologic changes differ from rheumatoid arthritis and there is no inflammation of the capsules as in other case. There are degenerative changes with fibrillation of the articular cartilage at the place of the greatest weight, bearing or use, usually in the central portion of the joint. These degenerative changes advance with the progress of the disease, the cartilage becomes thinned and the surface irregular. Further progress of the

disease leads to increased articular and osseous changes and irregularity of joint surface.

There is no evidence that oral sepsis is primarily concerned with the aetiology of this type of arthritis. However it is my clinical experience that a patient who complains of pain in the shoulders or knees is generally found to have infected teeth or tonsils, and they should be dealt with on their merits.

Conclusion

In appraising the problem of infection in relation to arthritis, the first consideration is to know whether the patient has arthritis, secondly, if he has, what kind of arthritis. Thirdly, whether a focus of infection is present, if so, whether the infection can reasonably be the cause of that type of arthritis. It is illogical to expect a cure of gonococcal arthritis by extracting the teeth even if they are infected. It is my clinical experience (though very limited) that patients with rheumatoid arthritis having abscessed teeth as the focus of infection have been cured by their removal. In osteo-arthritis the removal of the infected teeth was of no great help to the patient.

Lastly, I would like to appeal in this connection to the authorities responsible for the medical research that fresh attempts be encouraged for careful reconsideration and further clinical evaluation of this problem in our research institutes in Calcutta.

ULTRA-SHORT-WAVE THERAPY IN MEDICAL PRACTICE

By A. N. K. MENON, M.B., B.S., D.M.R. (Mad.)
Radiologist, Stanley Hospital, Madras

Short wave and its mode of action.—All electromagnetic waves are due to the rapid to and fro movements of electrical charges and are propagated as transverse oscillations in ether, while extraordinary rapid reactions in the atom are the basis of visible and still shorter wave radiations. The electric waves in the narrow sense of the Hertzian waves occur as the result of oscillations of fairly large electric charges in oscillatory circuits.

With a frequency of 10^8 cycles per second the wave-length is 3 metres and with 10^7 cycles per second it is 30 metres. The wave-lengths we are now concerned with are generally between 3 and 30 metres. Waves under 100 metres are called short while those under 10 metres are termed very short or ultra-short. Generally speaking, it is the electric field, as it exists between the condenser plates of a closed oscillatory circuit, and not the electromagnetic waves that is more used and as such it is not quite correct to name it 'Short-Wave Therapy' or 'Ultra-Short-Wave Therapy'. But the expression has become generally current and the division according to wave-length has proved very convenient.

Mode of action.—Under the influence of the electric field force between the condenser plates,

movements of molecules and ions take place and the energy becomes mostly changed into heat. The fundamental difference in the working of the short-wave field as compared with any of the usual currents hitherto used (e.g. diathermy) is that the energy does not flow through the dielectric as a purely conductive current but attacks the smallest particles themselves in the interior of the dielectric as a field force so that the nature and strength of the action depends on the composition of the dielectric. Two current components may be imagined to occur in the dielectric. (1) A conduction current component which results in producing heat. (2) A capacity component or displacement current which induces the deep-seated effect. This latter component comes into play when the frequency reaches to 10 million cycles or more corresponding to a wave-length of 30 metres or more.

There are two methods by which high frequency electric oscillations can be started. (1) Impulse production—spark gap method. The frequency by this method is about 1 million cycles corresponding to 300 to 500 metres. This is not used. (2) Valve transmission method. In this method undamped oscillations with high output can be started with electronic valves. An ultra-short-wave apparatus for general use must give an output of at least 300 watts with 4 to 6 metres effective wave-length. With a two-valve transmitter it is possible to change the wave-lengths between 3.25 and 7.2 metres. A transmitter with 350 watt output can be used for the production of wave-lengths of 6 to 12 metres. The apparatus used by me is a dual-wave generator, Model S.W. 55 of Westinghouse Electrical International Company, working in U.S.A., at 230 volts and at 6 amperage.

Technical detail of the apparatus and its working is omitted due to lack of space.

Effects of short-wave-condenser field in liquids, tissues and organs

Every tissue has an optimum wave-length, the application of which would produce the maximum warming effect. When equal quantities of full blood, serum and clot from the same specimen were subjected to a field of 3 metres wave-length, it was found that the full blood was heated to about 10.5°C., the serum to about 8.5°C. and the clot to 11.5°C. The R.B.C. even in undiluted blood resist heat more strongly than the serum.

Human tissues.—Within a piece of tissue in the body single or group of cells or even parts of cells behave differently from those in their close proximity. A selective heating of individual part takes place depending on the composition of the part. Bacteria may also react independently of their nutrient reaction of the tissue attacked by them.

Field exposures over 20 minutes have been found to produce decrease in the viscosity in colloids in human serum and produces changes

in surface tension. Toxicity was found much lowered when diphtheria toxins were exposed to condenser fields. Phagocytic power of the leucocytes was influenced by the condenser field, with a moderate dose, phagocytosis was greatly stimulated and the phagocytic index increased. In the living body there is an increase of the antitoxin formation by ultra-short-wave treatment. A 15-metre wave reduces the blood pressure. Some asthmatics react excellently to 12 metres while some others show improvement only with 4-metre waves. In therapeutic measures the bacteria are not completely destroyed but their destruction is hastened by the improvement of protective powers and by the weakening of the bacteria themselves. Blood clotting is markedly increased by the treatment. A rise in cholesterol is noticed after irradiation of spleen. Radiation in the testis causes good spermatogenesis. Short-wave treatment lowers the tone of the sympathetic system and stimulates the parasympathetic system. A stronger heating is noticed in inflamed tissues. Even though Schereschewsky noticed a decline in the growth of inoculation sarcoma in rats, the treatment of malignant disease should go to the province of x-rays and radium and a distinct warning against any premature optimism regarding treatment by short waves in these cases should be given.

Treatment of human diseases

Ettingen and Schliepake, after a series of experiments on animals and on themselves for about two years, found that injuries occurred only after very heavy doses such as were given to small animals in powerful field concentrations. The well-known injuries due to x-rays were always in their minds. Pain occurred when certain field strengths were exceeded and generally between the occurrence of unpleasant sensation and the administration of a really injurious dosage there was found to be always a sufficiently long interval.

Technique.—The patient should be in a comfortable position. Changing should not involve much trouble. With modern apparatus, the secondary circuit with the electrodes can be easily applied to the patient in various positions. If lying, the patient should be placed on a steady table made of wood or some insulating material with as few metal parts as possible. The best underlay for the patient is rubber sponge. The patient should be as free as possible. It will be an advantage if the table is provided with rollers so that the patient can be easily adjusted by the side of the transmitter. In arranging the electrodes it is important to see that they are made fast in the correct position and the right distance from the body. The body must be held as firmly as possible between the plates.

Results of treatment

Furuncles.—The first case treated and cured was an extremely painful furuncle on the nose

of Schliepake himself in March 1929 at the medical clinic of Jena. The seat of trouble was close to the point of the nose and the condenser plates were each of a diameter of 5 cm. and were placed on either side of the affected part at a distance of about 5 mm. The treatment was continued for about 5 minutes by which time the very unpleasant sensation of tension and pain disappeared. The following day the furuncle was much smaller and by the second day it was completely absorbed. In 500 cases of furuncles treated by Schliepake there was only one failure and that was due to the patient not following the instructions but continuing his own treatment with the application of ointments, etc. These included furuncles in all stages of development.

The electrodes applied must be at least as large as the inflamed area. It is generally advisable to use 10 cm. electrodes. For a single treatment 10 to 15 minutes is as a rule sufficient. The effect of waves under 6 cm. is the best. One sitting per day is enough. The average time required for a complete cure of the furuncle was 4 to 6 days. The majority of simple furuncles take only 2 to 3 days.

I treated two cases of furuncles and both were cured in 4 days. Time used was 10 minutes. Case 1 had a bad furuncle in the nose with cellulitis all around and was sent to me by the E. N. T. Surgeon for infra-red therapy. He was given ultra-short-wave therapy instead. The patient was in great distress and on the first day he was given a sitting for 10 minutes. The pain was greatly relieved on the first day itself but swelling persisted for two days more. On the fourth day the swelling completely disappeared and there was no sign of the furuncle.

Whitlows and paronychia.—In these groups of cases the treatment is simple for the finger is just placed in between the two condenser plates, the treatment lasting for about 20 to 30 minutes. Schliepake had treated cases in all stages of the disease. None of the cases required surgical intervention. Recently two cases were treated by me by ultra-short-wave. Case 1, a nurse, had injured her index finger while closing a door which rapidly developed into tenosynovitis and lymphangitis. The finger and the corresponding part of the hand were infiltrated with pus. There was great relief of pain after the first day's treatment and the swelling also subsided to a very great extent. The condition completely cleared up after treatment for two more days.

Carbuncles.—Schliepake had treated carbuncles of various sizes with good results in all the cases. The treatment adopted was more or less the same as that adopted for furuncles excepting for the fact that each sitting was of half an hour's duration with 6-metre waves. In very large carbuncles it took 2 to 3 weeks.

Hidradenitis.—The results are good in the treatment of abscesses of the axilla. Sitzings of 20 minutes' duration a day were enough and

most of the cases were cured in four sittings, the longest being 8 sittings.

Dental diseases.—In dental and oral diseases (as dental sinus, root abscess, gingivitis, stomatitis, etc.) the treatment is best carried out by placing a 10 cm. plate on each side of the face. The duration of the treatment varies from 10 to 30 minutes depending on the nature and severity of the disease. According to Heisse, gingivitis and stomatitis in 75 specially long cases were cured after 6 to 8 radiations. Osteomyelitis of the jaw is dealt with especially in children. The discharge from the sinus almost always increases at first and the extrusion of the sequestrum and drying up of the sinus follow.

Empyema of nasal sinus.—Especially in the treatment of empyema of Highmore's antrum 10 cm. plates are best placed laterally on each cheek so that the eye does not come into the line of fire between the electrodes. The distance of the plates is 3 cm. being less on the affected side— $\frac{1}{2}$ to 2 cm. with 3 to 6-metre waves. Acute and sub-acute cases react very quickly. Usually there is an increase in the headache and fatigue after the first application or two, but this is relieved after three sittings.

Catarrh of the upper air passages.—The effects of short wave on catarrhal diseases are singular. With colds all the symptoms completely disappear the day after the treatment and often in 2 or 3 hours. The results are also very satisfactory in cases of laryngitis and tonsillitis.

Arthritic or joint diseases and lumbago (fibrositis).—A thorough examination of the case has to be made and decision arrived at as to whether a local treatment would suffice and if so when it should be applied. The deciding factor in these cases is to find out whether one is dealing with a disease which is self-limited or has a focal infection elsewhere. If the latter, the treatment must first be applied to the focus and subsequently to the diseased organ. The treatment at each sitting lasts from 10 to 20 minutes and the energy should be sufficient to produce a great feeling of warmth. The course in individual cases varies. Sometimes the pain which disappears for several hours after the first sitting returns. Large effusions have been absorbed after five or six sittings. In muscular rheumatism, relief often comes with dramatic suddenness. In the four cases treated by me (cases of arthritis), all were relieved of their pain and were able to use their affected joint actively. In one case of a lady lecturer, aged 32 years, there was great pain and the patient was unable to use her left hip joint. She had lightning pains in her cervical vertebral region. She was bedridden and the history went back as far as twelve years. Radiographs did not reveal any definite bony lesion excepting a slight narrowing of the joint spaces. She has had fifteen sittings of ultra-short-wave therapy of 10 minutes each to her left hip joint and cervical region. She has at present no pain, sleeps well and can freely use her left hip joint

and move her neck without any pain or discomfort. She is still continuing her treatment.

Abdominal diseases.—Chronic appendicitis and adhesions in the abdomen due to previous peritonitis or pelvic cellulitis are the types of cases which are admirably suited for ultra-short-wave therapy.

A 30-year-old girl who had pain in the lower abdomen with marked tenderness in the right iliac region accompanied by dyspepsia and emaciation was given fourteen sittings of ultra-short-wave therapy to the lower abdomen, each sitting being of 15 minutes' duration. This completely relieved her condition.

Gynaecological cases.—Diseases of the adnexa are very suitable for ultra-short-wave therapy. Two cases were treated by me and both have completely recovered. One case, a nurse, was frequently getting attacks of salpingitis and on the last occasion the pain was so intense that she fainted. She was given ten sittings of 10 minutes each, which resolved the condition completely. She has had no further attacks for the last four months.

Lung diseases.—The treatment of focal lung disease by ultra-short-wave therapy is very promising. With local foci we have very favourable dielectric conditions. As the lung tissue is full of air, dielectric losses must be comparatively less than in compact masses of tissues. The removal of the heat which is only produced in the interalveolar septi is very greatly facilitated by the freely circulating large quantities of blood in the lungs. It is therefore possible to use very powerful energies without fear of injury to the lung tissue (healthy).

Mode of treatment.—Plates of a diameter of 20 cm. are placed in front and behind the diseased side of the patient. This can also be done with the patient lying on his side or back, and in the latter case one of the electrodes can be placed under the table. There is no absolute standard for the strength of the condenser field. Generally, the strength is so adjusted that the patient feels a pleasant warmth in the inside of his chest. To start with the sittings can be of 10 minutes' duration with medium energy. The patient must be under observation and the treatment can be increased up to 20 minutes. If the patient gets a feeling of increased pressure inside his chest with mild dyspnoea setting in about 2 to 3 hours after treatment, as a result of pulmonary hyperæmia, the field strength and the duration of each sitting should on no account be increased further. I have had no experience of acute pneumonia being treated with ultra-short-waves but in my hands chronic unresolved pneumonias and abscesses of the lungs have responded favourably. Cases of bronchiectasis also give good results provided they are not too far advanced.

Case 1.—N., aged 40, had an attack of pneumonic involving the upper and mid-zones of the right lung field. He was treated by a

private medical practitioner for about a month. It is said that all available remedies including sulphonamides were tried to no purpose. The temperature ranged between 100° and 101°F. with cough and expectoration. Repeated examination of the sputum did not reveal any Koch's bacillus. In this condition he was admitted to hospital on 29th May, 1946, and sent for ultra-short-wave therapy. An x-ray photograph was taken which showed opacity at the upper and mid-zones (see figure 1, plate XIV). His pulse rate and temperature were 110 per minute and 101°F., respectively. On the first day ultra-short-wave therapy was given for 10 minutes, the condenser plates being placed in front and behind the affected side of the chest. Next day the time was increased to 15 minutes. On the third day the temperature touched normal. After 20 sittings the patient was discharged cured, subsequent radiographs showing the pneumonic patches completely cleared up (see figure 2, plate XIV).

Case 2.—C., a boy, aged 10 years, was treated for unresolved pneumonia at the right base for 10 days with a 10 minutes' sitting per day. The pneumonic area completely cleared up and he was discharged cured. But two weeks later the patient was reported to have died of some unknown cause.

Case 3.—A., aged 49, was sent for ultra-short-wave treatment with a history of cough for two months bringing forth foul-smelling sputum. On percussion there was a resonant area in the upper one-third of the right lung and on auscultation amphoric breathing with a few crepitations was heard over this area. Sputum was negative for Koch's bacilli but showed pus cells. A radiograph of the chest was taken which showed a thick-walled cavity with a fluid level on the upper zone of the right lung field with consolidation around (see figure 3, plate XIV). This confirmed the diagnosis of abscess of the lung. His temperature was 101.5°F. Ultra-short-wave therapy was given to the upper half of the right lung field, starting with a sitting of 10 minutes' duration for the first day. It was increased to 15 minutes on the second day. The temperature touched normal on the 4th day. The patient became more and more cheerful and altogether twenty sittings of 15 minutes each were given to him. A radiograph taken on the 20th day showed that the pneumonic area around the cavity had cleared up, there was no fluid level within the cavity and the cavity walls were very thin and disappearing (see figure 4, plate XIV). The patient discontinued treatment even though he was advised to continue it.

Diseases of the pleura.—Pleurisy with effusion, pleural empyema and dry pleurisy respond very favourably to ultra-short-wave therapy. Two cases of pleurisy with effusion were treated by me—Munuswamy and Ahmed Khan. They were both given ultra-short-wave sittings for 15 days with 15 minutes' duration per day. In both

cases the results were good, the effusions were practically absorbed.

Two cases of dry pleurisy. Ahmed Khan and Raju were given 14 and 25 sittings respectively of ultra-short-wave for 10 minutes at each sitting. In both cases the results were good. The case of Raju is interesting.

Raju, aged 35 years, male, Hindu, police constable by profession.

Complaint.—Cough with sometimes blood-stained sputum for the last three months and with pain on the left side for the last one week. He was admitted into the Pentland Ward on 6th May, 1946. X-ray of the chest showed diffused irregular opacity in the base and lower zones of the left lung field (see figure 5, plate XIV).

Urine.—No albumin nor sugar.

Respiratory system.—Movement of the left side of the chest is less than that of the right. Breath sounds much diminished at the left base with tenderness on percussion over this area.

Heart.—Nil abnormal.

Liver and spleen.—Not palpable.

About ten days of intensive medical treatment did not give any relief to the pain and so he was sent for ultra-short-wave therapy. He was given sittings of 10 minutes' duration for 25 days when the opacity at the left base cleared up and the pain disappeared (see figure 6, plate XIV).

Osteomyelitis, erysipelas, chronic eczema of the skin, diseases of the eye as abscesses of the lids, phlegmons of the lachrymal sac, inflammations of the orbit with ophthalmos and ulcus serpens are all supposed to respond very favourably to ultra-short-wave therapy according to Schliepake. Short ultra-wave therapy has come to stay and has a definite place in modern medical practice. In the hands of an expert it is a powerful weapon in the fight against disease. As is always the case in therapy of this kind it is the man behind the machine that is more important than the machine itself and it will be a real boon to suffering mankind only if it is used by experts, that is, by those who know how to use it.

I thank Rao Bahadur Capt. M. G. Kini, M.C., F.R.C.S., M.Ch. (Ortho.), etc., Superintendent, Government Stanley Hospital, Madras, for his invaluable help and encouragement.

AN UNUSUAL PHENOMENON IN STRYCHNINE CONVULSIONS

By A. M. J. SHIRAZI, M.Sc., M.B., B.S.

IN the Pharmacology Department, Stanley Medical College, Madras, it was considered worth while to test the margin of safety claimed by the British Pharmacopœia for the maximum dose of some of the toxic drugs; amongst the many toxic substances that suggested themselves, strychnine was considered the safest, as the antidote is well known and its action almost quantitative. After consideration of all factors it was considered reasonable that I personally should become the subject of study since it would be advantageous from the point of view noting the symptoms and signs, their order of occurrence and their relative severity.

The train of symptoms and signs of strychnine poisoning are very well described in textbooks of pharmacology (Sollmann, 1942). It is stated that, with 6 to 7 mg. in man, tautness of muscles and twitchings occur; and that with toxic doses, convulsions and other phenomena appear. The British Pharmacopœia maximum dose is well below the toxic dose, and therefore it was considered safe to take the maximum B. P. dose + 25 per cent; as a safeguard it was proposed to keep ready an ampoule of any one of the barbiturates, so that if the train of untoward symptoms set in it may be administered.

With the above object in view a capsule was filled with 10 mg. of strychnine hydrochloride (pure quality recrystallized) and swallowed at 7.45 p.m. By oversight the ampoule of sodium amytal was left behind in the laboratory, and at 8.45 p.m., while I was at dinner, the following symptoms and signs of toxicity were observed.

They began with short sudden attacks of a peculiar sensation in the throat which was not exactly painful nor choking but a combination of both, specially when the mouth was opened. Within about three minutes the act of swallowing was slightly painful, and the masseters were felt to be taut. In another minute or two attacks of dizziness affecting both the eyes were observed. These were very transitory in the beginning, but were soon replaced by more lasting but interrupted attacks, occurring at intervals of a minute or thereabouts.

Till now the other voluntary muscles had not been involved; but from now on (that is, from about ten minutes from the onset of the symptoms) these began to twitch and then became taut one by one, and within five minutes all voluntary muscles had been involved. The first group of muscles were those of the neck which became taut. It was then observed that the elbow could not be extended easily to lift a spoon because of the hypertonicity of the flexors. I got up from my seat and walked to the bed. While walking it was observed

that there was a tingling sensation in the soles of the feet and the extensors were felt to be taut. After a few paces I found it necessary to drag the feet as the flexion at the knee gave rise to tremors in both of the antagonistic groups of thigh muscles. There were no more attacks of dizziness, but the room appeared to be dim. In the eyelids I could feel the orbicularis oculi contracting in rings. While I was lying in the bed and waiting for the doctor, a number of reflexes were tried as the body lay in the 'bear' position, the elbows flexed over the chest, and also the wrists; the thighs extended, adducted, and internally rotated, the knee and ankle joints extended, with plantar flexion of the great toe. A sudden stimulus of light, sound or touch gave rise to an exaggeration of the position of the lower limbs, while the upper limbs went into athetoid movements at the elbows and twitchings of the muscles of the forearm and the fingers. A continuous non-varying stimulus had no effect. There was one constant feature throughout, namely, that with determination it was possible to inhibit a response to a stimulus. For instance an attack was expected when an injection of apomorphine was given an hour and a half after swallowing the drug (the attending physician's suggestion; in my opinion this was too late), but while vomiting it was possible to inhibit to a considerable extent the convulsions. Moreover, deliberate movements such as deep breathing, forced yawning were tried to note if an acute attack would be precipitated, and the diaphragm would contract. This did not occur.

During this period there were attacks followed by periods of rest. The rest did not consist of complete relaxation, but of a definitely more comfortable state than that of convulsions, the body still being in the 'bear' position.

I was removed to the General Hospital Outpatients Department, and there, while waiting for the sodium amytal ampoule from the dispensary, a sudden and complete relaxation of all the muscles took place so as to permit free movements at all joints, the 'rings' that were felt in the eyelids disappeared, and the vision became normal. I tried to get out of the stretcher, but the housemen would not let me do so and insisted on the sodium amytal being administered. Three minutes later, the barbiturate was administered subcutaneously, but there was no difference whatsoever between the state prior to and after the injection. This last phenomenon of sudden and complete relaxation was permanent; it seems to be unusual and does not seem to have been recorded in the literature. I have failed to find any reference in the available books, and hence the paper.

Discussion

Dose.—It has been reported (Sollmann, 1942) that 5 to 10 mg. may produce convulsions

and that with 20 to 30 mg. they definitely occur. The British Pharmacopœia's maximum dose is $1/8$ grain or 8 mg. The dose administered was only 25 per cent more than this maximum dose, and the British Pharmacopœia claims a greater margin with toxic substances. However, 10 mg. seems to be sufficient to produce convulsions; the convulsive dose for a frog is 0.75 mg./kg., and that for man is $1/6$ of that for frogs (both convulsive and fatal), that is 0.125 mg./kg. In this particular case the convulsive dose seems to be 0.1 mg./kg., and most probably this explains why untoward symptoms and signs such as involvement of the diaphragm and cyanosis did not take place. Therefore, the British Pharmacopœia's maximum therapeutic dose may be well below the toxic limits, but the margin of safety is not very wide.

Symptoms and signs.—The peculiar sensation in the throat is not mentioned in the available literature; this was the first thing to attract my attention; of course, there have been descriptions of a 'mechanical cry' in the literature. It cannot be explained by fixation of the cords of adduction or abduction; I did not find any change in my voice with all the acuity of hearing that I possessed, neither could those surrounding me appreciate any.

Secondly, there seemed to be an order of involvement of the voluntary muscles, in addition to the order in which the special senses were involved; that is if the peculiar sensation in the throat and dizziness is considered an involvement. The order of involvement of the voluntary muscles was the masseters, the neck muscles, the arm muscles and then the leg muscles.

Thirdly, the position of the limbs described in the literature and above was the 'bear position'; it is known that this is the position of the body after decerebration. There is no doubt that there is a response to a sudden stimulus and not to a continuous one, as with any other physiological reflex. Cushny (1920) considered the response to be a homologue of the start reflex. The 'start reflex' is considered a protective one, and hence there will be a flexor tone rather than an extensor one. The cerebral inhibition over the muscles seems to be removed. Sollmann mentions that in patients suffering from cerebral lesions, the paralysed muscles are the first to be involved after strychnine administration. This further supports the above contention; the group of muscles without the cortical inhibition become relatively hyperactive.

Fourthly, it is a fact that the Sherrington's reciprocal inhibition is lost, and hence the simultaneous contractions in the antagonistic groups of muscles, but this is only after the body assumes the 'bear position'. It is in this position that one observes the fact that the antagonists are not reciprocally relaxing, thus causing tremors and athetoid movements; but

this does not explain why the upper limbs occupied this position of flexion, or why the lower limbs took up a position of extension, adduction and internal rotation. The position of the body and the absence of Sherrington's reciprocal inhibition indicate that the inhibitory control of the cortex, as well as that of the cord, is lost. Hence it is an abolition of the inhibitory reflexes of the central nervous system but not including the autonomic.

The only unusual phenomenon was the sudden release of all the muscles from their position and tone before administration of barbiturates. A reference to this I have failed to find in the available literature.

EVALUATION OF PROTHROMBIN RESPONSE TO VITAMIN K AS LIVER FUNCTION TEST

By P. N. WAHI, M.D., M.R.C.P. (Lond.)

Department of Pathology, Medical College, Agra

THE prothrombin of the blood is elaborated in the liver. Andrus *et al.* (1939), and Warren and Rhoads (1939) produced experimental evidence in support of this hypothesis. By total and partial hepatectomy in animals they produced a profound reduction in plasma prothrombin concentration which was unaffected by treatment with vitamin K and bile salts. It has been found essential to have vitamin K for the production of prothrombin, the level of which falls in subjects with vitamin K deficiency. The exact rôle which vitamin K plays in the formation of prothrombin is yet to be decided. Is it a necessary constituent of prothrombin or does it act as a stimulus to the liver for the formation of prothrombin? Evidence is against the former contention, since pure prothrombin preparations do not have a naphthaquinone structure. Quick (1943) described prothrombin as composed of calcium and two separate components, one of which is stable and is probably related to the oxidation-reduction systems of the blood, and the other is heat labile and inactivated by decumarol.

Bile is essential for the proper absorption of natural vitamin K. Synthetic vitamin K analogues, particularly those which are water soluble, do not need bile salts for their absorption, if given in adequate doses. It is not certain as to the exact place of absorption from the bowel. Butt and Snell (1941) believe that it is absorbed through the upper part of small intestine. Javert and Macri (1941) mention that mineral oils taken internally inhibit the absorption of vitamin K. They dissolve vitamin K, and not being absorbed, are voided

with faeces, taking with them the vitamin K. Liver acts as a store-house for vitamin K though only small amounts are stored. Increased prothrombin time may be due to inadequate intake of vitamin K or the failure to absorb this fat soluble vitamin, specially in the absence of bile which is necessary for the absorption of fats (Wilson, 1940). The prothrombin response to vitamin K has been claimed to be highly sensitive test of liver function, since the hypoprothrombinæmia associated with severe liver damage does not respond to vitamin K therapy. Lucia and Aggeler (1941) disclaimed this view pointing that although hypoprothrombinæmia in cases of acute diseases of liver did not respond well to vitamin K there was no significant correlation between the hippuric acid excretion and plasma prothrombin either before or after administration of vitamin K. The findings of Kark *et al.* (1941) also support this view. However, it is an accepted fact that in acute and chronic affections of liver, there is generally an initial prothrombopenia which is not corrected appreciably after the administration of vitamin K. It is also helpful in differentiating obstructive from intrahepatic jaundice as in the former the prothrombin time usually returns towards normal following the administration of the vitamin K (Simmons and Gentzkow, 1944). Lord and Andrus (1941) found that there was a rise of from 10 to 62 per cent in the plasma prothrombin following intramuscular injection of 2-methyl-1:4-naphthaquinone in extrahepatic jaundice (common duct stricture, cholangitis, carcinoma of the head of the pancreas, etc.), while in cases of intrahepatic jaundice the response was 10 per cent or less. Kark and Souter (1941) also came to the conclusion that in patients with intense jaundice the return of low prothrombin level to normal after vitamin K therapy is in favour of a diagnosis of obstructive extrahepatic jaundice.

The observations noted in this paper are a result of my studies to correlate the hepatic function tests with liver biopsy findings. During these studies which included all types of liver affections, it became obvious that all such cases had hypoprothrombinæmia, which showed a varying response to parenteral administration of vitamin K. To correctly evaluate the response to vitamin K, hippuric acid synthesis test was done in all cases. In all these cases histological examination of the needle biopsy material was also done to correctly diagnose the nature of liver involvement.

The vitamin used in the work was 2-methyl-1:4-naphthaquinone (Menaphthone B.P.)-Prokayvit, (B.D.H.) in doses of 10 mg. injections intramuscularly. The prothrombin time was determined before and after 24 hours of injection of vitamin K. The method used was the modified technique of Iyengar *et al.* (1942). Hippuric acid test was done by the intravenous technique of Quick. Liver biopsy was performed with the Vim-Silverman needle (Wahi, 1946).

Thirty cases of liver disease have been investigated. Among these cases were patients of portal and biliary cirrhosis, malignant growths of liver, subacute hepatitis, amyloidosis and reticulo-endotheliosis of liver, jaundice and congestive heart failure. In all these cases plasma prothrombin level before and after administration of vitamin K and hippuric acid excretion was determined. The results are charted in the table.

Discussion

From the detailed analysis of the above cases, some interesting conclusions can be derived. Cases 2, 6 and 18 had jaundice, as the presenting symptom. They all had marked hypoprothrombinemia; but on the administration of synthetic vitamin K, they showed a very good response. This implies that these cases had no gross liver parenchymatous

TABLE

Comparative studies of response to vitamin K and hippuric acid in patients with liver disease

30. K.	Do.	Do.	40	50	0.35

lesion and the low prothrombin level was therefore not due to failure of formation of prothrombin, but to failure of absorption from bowel due to absence of bile. With the administration of synthetic vitamin K (which does not require bile for its absorption) the prothrombin level went up. The jaundice was therefore obstructive in type. This was confirmed by the liver biopsy findings. Jaundice in case 18 was probably due to obstruction of the common bile duct at the porta hepatis. These cases conform to group I of Kark and Souter (1941).

Cases 1, 3, 5, 8, 9 and 10 also had jaundice and initial hypoprothrombinæmia. But the response to vitamin K was poor and prothrombin level never reached normal. This group of jaundiced cases had chronic parenchymatous lesion of the liver of long standing. This is confirmed by the histological findings of the biopsy material from the liver. Hypoprothrombinæmia was due to non-formation of prothrombin and not to deficient supply of vitamin K. These two different types of response to vitamin K therapy in cases of jaundice thus help to differentiate between obstructive jaundice and jaundice due to parenchymatous lesion. This, I think, is the greatest use of this test.

Another group of cases (20, 21, 22, 23, 27 and 28), clinically diagnosed as congestive heart failure and histologically showing dilatation of capillaries, cloudy swelling and fatty degeneration of liver cells, showed marked initial prothrombinopænia, but the vitamin K response was good, though the prothrombin level never reached normal figures. These cases had parenchymatous liver damage of a moderate degree. The hypoprothrombinæmia was due to pressure on the interhepatic biliary ducts by the swollen cells and dilated capillaries, leading to diminished flow of bile and consequent diminished absorption of vitamin K from bowel. Besides due to moderate degree of parenchymatous lesion (cloudy swelling and fatty degeneration in the cells) there was also deficient production of prothrombin; and hence after the administration of synthetic vitamin K the prothrombin level never reached normal range. These cases correspond to group II of Kark and Souter (1941). When such cases (24, 25, 26, 29 and 30) develop chronic hepatitis (as shown by patches of necrosis and fibrosis), they show very poor response to vitamin K. The vitamin K response test may be useful to the cardiologist in finding the possibility of enlarged liver of heart failure, returning to normal. Cases with poor response where level of prothrombin fluctuates within certain subnormal limits irrespective of vitamin K administration show that the patient is developing cardiac cirrhosis and the liver will not return to its normal size.

Cases 1, 3, 4, 9, 10, 11, 14 and 17 had initial prothrombinopænia which did not appreciably respond to vitamin K; the final level of prothrombin always remaining subnormal. These

are the cases of chronic and long-standing liver affection; where liver cells were markedly damaged resulting in deficient formation of prothrombin (group IV of Kark and Souter).

From these findings it is evident that initial hypoprothrombinæmia may be due either to defective formation of prothrombin in the liver or to defective absorption of vitamin K from bowel. In the latter cases administration of synthetic vitamin K will correct the initial hypoprothrombinæmia and raise the prothrombin level to normal. In the former cases the vitamin K therapy will not produce any appreciable change. The vitamin K response is thus of great use in differentiating between obstructive jaundice and one due to parenchymatous liver lesion. Besides, the reaction is also helpful in pointing out the presence or absence of liver damage when jaundice is not present. Cases 12 and 13 were both clinically diagnosed as cirrhosis liver. The prothrombin response to vitamin K was very good, the concentration reaching normal. This showed that liver was not damaged and this conclusion was confirmed by the liver biopsy findings, which showed the liver histology as normal. In contrast to this is case 10 which was diagnosed as endemic ascites (the underlying liver condition being doubtful), showed poor vitamin K response indicating liver damage. On liver biopsy it was found to be a case of portal cirrhosis.

In all these cases, hippuric acid excretion was also estimated and the table shows a comparative study of hippuric acid excretion and plasma prothrombin level. It is clear that in all the cases of liver disease (as proved by liver biopsy), the plasma prothrombin level determination before and after vitamin K therapy was as sensitive a test of liver dysfunction as hippuric acid excretion. But there is no correlation between the two in showing the extent of the liver damage.

Summary

Patients with liver damage show an initial hypoprothrombinemia and a poor response after vitamin K therapy.

In cases with intense jaundice there is a low level of plasma prothrombin. If after administration of vitamin K there is a rapid return of the prothrombin level to normal, the jaundice is likely to be obstructive, while if the response is poor, there is liver parenchymatous lesion present.

In the comparative study of cases, the vitamin K response has been found to be as good a test of liver damage as hippuric acid, but no correlation exists between the two in showing the extent of liver damage.

I wish to thank Prof. G. N. Vyas and Dr. K. N. Gaur, Dr. K. S. Mathur and B. K. Dube for giving me facilities to work on their cases. I am particularly grateful to Dr. Kashi Nath for his constant help.

The vitamin K used in this work was Prokayvit (Menaphthone B.D.H.) supplied free by the British

Drug Houses Ltd., London, and I am grateful to them.

PROGNOSTIC SIGNIFICANCE OF LEUCOCYTIC COUNT IN BUBONIC PLAGUE

By P. M. WAGLE, M.D., D.P.H.

and

R. B. M. COLAH, M.Sc.

(From the Haffkine Institute, Bombay)

THE leucocytic reaction and its significance from the prognostic point of view have been worked out in several infectious diseases, particularly in pneumonia in adults and children, and it has been recognized that in human beings a high leucocytic level during the course of pneumococcal infection is associated with a more favourable prognosis. Several workers, Middleton and Gibbon (1930), Meyer (1931) and Tilghman and Finland (1937), have found that a leucocytic count of between 15,000 to 35,000 cells is attended with a more favourable prognosis than either a leucopenia or a very high count of over 40,000 cells. We are not aware of any work on similar lines having been done in human plague infections so far and we, therefore, give in the present communication, an analysis of the leucocytic reaction observed in 446 cases of human bubonic plague and its relationship to incidence of septicæmia and mortality. An opportunity for this study occurred when the various drugs of the sulphonamide series were being tried in the field by the senior author with a view to assessing their curative value in the treatment of human bubonic plague. It was noticed during these trials that those cases which showed a leucocytic count of over 40,000 cells per c.mm., either on admission or during the course of the acute

phase of the disease, almost always headed towards a fatal termination. This suggested that the total leucocytic count may serve as a rough index of the severity of plague infection and possibly as a guide to prognosis in bubonic plague. We have, therefore, analysed the records of 446 cases in which the total leucocytic count was done on admission and thereafter on alternate days till the temperature came to normal, or the case terminated fatally. The results are recorded below. The cases include those of all ages and all grades of severity including those that died within 24 hours. At least two counts have been done in each case except those which died too early to permit of more than one count. Thus in 73 cases which died in 24 hours or so only one count was done, in 97 cases two counts were done and in the remaining 276 cases three counts were done. The highest count obtained was taken into account for purposes of analysis. Table I shows the relation of the total leucocytic count to mortality in these 446 cases.

TABLE I

Relation of the leucocytic count to mortality in 446 plague cases

Leucocytic count, thousands	Number of cases	Deaths	Mortality, per cent
Less than 5 ..	6	3	50.0
5 to 10 ..	79	14	17.7
10 to 20 ..	216	39	18.0
20 to 30 ..	70	37	52.8
30 to 40 ..	37	27	72.9
Over 40 ..	38	37	97.3

It will be seen that cases having a leucocytic count of below 5,000 had a mortality of 50.0 per cent, while the mortality was 17.0 to 18.0 per cent in cases showing a leucocytic response of 5,000 to 20,000 cells. With increasing leucocytic response, the mortality increased. In cases with a leucocytic count of over 40,000 cells per c.mm., the mortality was extremely high, that is, 97.3 per cent.

The main factor which determines the severity of plague infection and the probable outcome in any plague case is the absence or presence of septicæmia and its degree. To detect the presence or absence of septicæmia, 0.5 c.c. of blood was drawn from a vein of the patient on admission and spread in equal quantities on two agar slopes. The cultures were seen after incubating the slopes for two days at room temperature (27°C.). If the culture was negative the case was taken as non-septicæmic and in these cases the prognosis was favourable and the mortality very low. If the culture was positive the case was called 'septicæmic' and the number of colonies on the agar slopes were noted. In septicæmic cases the outlook was more grave. It was found in the various trials that it was not merely the

presence of septicaemia that influenced the final outcome in any particular case but also the degree of septicaemia present at the commencement of treatment. Cases that showed a mild degree of septicaemia (1 to 10 colonies in 0.25 c.c. of blood) had a much lower mortality than those that showed a severe degree of septicaemia, i.e. a colony count of more than 10 colonies in 0.25 c.c. of blood. The mortality rate obtained in human plague cases of different severities is given in table II.

leucocytic count of 5,000 to 10,000, out of 79 cases, 35 or 44.3 per cent were septicaemic and in group 3, with 10,000 to 20,000 leucocytes, out of 216 cases, 105 or 48.6 per cent showed septicaemia. The mortality corresponded to the proportion of septicaemic cases in each group except in the group where the count was less than 5,000 (see chart). In cases in which the leucocytic count was less than 5,000, the death-rate was higher in comparison to the incidence of septicaemia.

TABLE II
Percentage mortality in plague cases of different severities

Treatment	Non-septicaemic cases	Septicaemic cases	Mild septicaemic case 1-10 colonies in 0.25 c.c. blood	Severe septicaemic cases. More than 10 colonies in 0.25 c.c. blood
Pasteur and Lister Institute sera. Plague Commission (1912).	25.9	91.2	74.5	100.0
Haffkine Institute serum. Naidu and Mackie (1931).	15.0	52.1	12.5	73.3
Haffkine Institute serum. Sokhey and Wagle (1940-41).	1.1	50.7	24.1	69.0
Sulphonamides. Sokhey and Wagle. (1940-41).	5.2	39.3	16.2	50.5

If the 446 cases that form the subject matter of the paper alone are considered the mortality rate worked at 7.0 per cent in non-septicaemic, 54.9 per cent in septicaemic, 21.8 per cent in mild septicaemic and 65.8 per cent in severe septicaemic cases. It is evident from this that although the mortality in plague cases of different severities has been reduced as a result of improvements in treatment, it has always remained considerably higher in septicaemic than in non-septicaemic cases, and in severe septicaemic than in mild septicaemic cases.

If the cases are grouped according to their leucocytic response and classified into septicaemic and non-septicaemic (table III), it will be observed that with the increase in the level of the leucocytic count, the percentage of septicaemic cases in that group also increased (table III, last column). Thus in group 2 showing a

CHART

TABLE III
Leucocytic count and its relation to septicaemia and mortality

Group	Leucocytic count, thousands	SEPTICAEMIC CASES			NON-SEPTICAEMIC CASES			Percentage of septicaemic cases in the group
		Number of cases	Deaths	Mortality, per cent	Number of cases	Deaths	Mortality, per cent	
1	Less than 5	2	2	100.0	4	1	25.0	33.3
2	5 to 10 ..	35	13	37.1	44	1	2.2	44.3
3	10 to 20 ..	105	32	30.4	111	7	6.3	48.6
4	20 to 30 ..	52	36	69.2	18	1	5.6	74.2
5	30 to 40 ..	30	24	80.0	7	3	42.8	81.0
6	Over 40 ..	38	37	97.3	100.0

The higher the leucocytic count, therefore, the greater the chances of septicæmia, and higher the mortality. Cases with a leucocytic count of over 40,000 cells were all septicæmic and, therefore, the mortality in these cases was almost cent per cent.

If we classify the septicæmic cases with different leucocytic levels into those showing mild septicæmia and severe septicæmia and study the distribution of severe septicæmic cases (table IV), we find that as the level of the leucocytic count rose the percentage of the mild septicæmic cases in the group decreased, while that of the severe septicæmic cases increased with the resultant increase in mortality. Exceptions were found in the severe septicæmic cases of groups 2 and 1 in which the mortality was disproportionately higher to the incidence of severe septicæmic cases, that is, 68.7 per cent and 100.0 per cent, respectively. It was also seen that the 38 cases which showed a leucocytic response of over 40,000 cells per c.mm., were all of severe septicæmic type.

that in a virulent infection like that of severe septicæmic plague, presence of normal count of 5,000 to 10,000 cells indicates lack of resistance on the part of the patient and thus a condition analogous to leucopænia. In cases which show leucopænia, that is, a count below 5,000, there is no correlation between the count, the incidence of septicæmia and mortality, but the number of such cases, however, is very small.

Sulphonamides are known to produce a leukæmoid reaction or a leucopænic condition by their toxic action, but all cases suspected to be showing these conditions as a result of the toxicity of the drugs have been excluded from the present series.

Summary

1. Four hundred and forty-six cases of bubonic plague treated with sulphonamides have been analysed with respect to leucocytic response, the incidence and degree of septicæmia, and the mortality.

TABLE IV

Table showing relation of leucocytic count to septicæmic cases of different degrees

Group	Leucocytic count, thousands	TOTAL SEPTICÆMIC CASES			MILD SEPTICÆMIC CASES			SEVERE SEPTICÆMIC CASES		
		Number of cases	Deaths	Mortality, per cent	Number of cases	Deaths	Mortality, per cent	Number of cases	Deaths	Mortality, per cent
1	Less than 5	2	2	100.0	1 (50.0%)	1	100.0	1 (50.0%)	1	100.0
2	5 to 10 ..	35	13	37.1	19 *(54.3%)	2	10.5	16 *(45.7%)	11	68.7
3	10 to 20 ..	105	32	30.4	34 (32.4%)	6	17.6	71 (67.6%)	26	36.6
4	20 to 30 ..	52	36	69.2	9 (17.3%)	5	55.5	43 (82.7%)	31	72.0
5	30 to 40 ..	30	24	80.0	1 (3.3%)	0	0.0	29 (97.7%)	24	82.7
6	Over 40 ..	38	37	97.3	38 (100.0%)	37	97.3

* Figures show in what percentage the mild and severe septicæmic cases are present in the total septicæmic cases in the group.

It is thus evident that in all cases in which the patient reacts to infection and the count rises over 10,000 cells per c.mm., the leucocytic count bears a close relation not only to the incidence and degree of septicæmia but also to mortality. In cases which show no response to infection and the count lies between 5,000 to 10,000 cells, the incidence of septicæmic and severe septicæmic cases is very low, that is, 44.3 per cent and 45.7 per cent, respectively, and, therefore, the mortality is also low in all cases except the severe septicæmic cases of this group, viz, 17.7 per cent in all cases, 37.1 per cent in septicæmic cases, and 10.5 per cent in mild septicæmic cases. In severe septicæmic cases of this group, the mortality is comparatively higher, that is, 68.7 per cent, and it is probable

2. The outcome of a case of bubonic plague is decided by the incidence of septicæmia and its degree. It was noted that progressively increasing leucocytosis indicated progressively increasing incidence of septicæmia and its increasing severity and consequently increasing mortality. With a leucocytic count of over 40,000 cells, all the cases showed extreme septicæmia and mortality was highest.

3. In cases which did not show leucocytosis and the count was between 5,000 to 10,000 cells, the incidence of septicæmia was lowest and prognosis favourable, but when severe septicæmic cases occurred, prognosis was unfavourable.

4. In cases which showed leucopænia, the prognosis was not favourable.

TROPICAL EOSINOPHILIA WITH MELÆNA AS COMPLICATION DURING ARSENICAL THERAPY

A CASE REPORT

By AMIR CHAND, F.R.C.P. (E.)

LIEUTENANT-COLONEL, I.M.S. (Retd.)

Professor of Medicine, Balak Ram Medical College, Lahore

and

DEVI CHAND GUPTA, M.B., B.S. (Pb.)

Clinical Assistant to the Professor of Medicine

THE patient R. R., aged 23 years, employed as a peon, was admitted on 2nd April, 1946, complaining of severe attacks of nocturnal dyspnoea and low-grade fever which had supervened since 2 months and cough with expectoration which he had for the previous 2 years. He was born and brought up at Gorakhpur (U. P.) and when 15 years old came to Lahore and stayed here for 3 years. He then had no symptoms. From here he went to Bombay and worked there as a chowkidar for nearly 2½ years. In the latter half of this stay he started getting dry cough in the mornings, with occasional attacks of sore throat and fever. He had two or three such attacks lasting 3 to 4 days each time and went to his native district where he got better. On returning to Bombay 2 months later his complaints recurred and increased in severity and paroxysms of respiratory distress also supervened. He felt feverish in the evenings, lost appetite and grew weak. Finding himself worse, he decided after a month to come to Lahore, where he tried various treatments with no relief. Ultimately thinking that he was getting tuberculosis he sought admission to Sir Ganga Ram Hospital for treatment. In his childhood he had suffered from cutaneous eruptions which might have been eczematous, otherwise he has suffered from no allergic complaints or any other notable illness in the past. His parents, who are dead, had no asthmatic trouble, nor has any of the 3 elder brothers and one sister suffered from this type of ailment. On admission he looked slightly wasted and sallow. He was getting bouts of persistent dry cough with asthmatic attacks at night during which moderate amount of mucoid sputum was expectorated. He ran a low-grade temperature, round about 99.5°F., in

the evenings. The average pulse rate was 84 to 90 p.m. The throat showed mild infection and voice was slightly husky. The chest was slightly hyper-resonant in all areas and showed medium rhonchi in both phases of respiration all over with occasional non-resonant crepitations of medium type at the bases. The spleen was 2 fingers below the costal margin. No other abnormality could be detected. Examination of the blood revealed the following picture:—

Hb.	100%
Total R.B.C.	4,750,000
Total W.B.C.	25,200
Differential count—			
Polymorphs	18%
Lymphocytes	8%
Large mononuclears	1%
Eosinophils	73%

Repeated stool examination revealed no abnormality nor any cause of allergy. The sputum showed large number of eosinophils and was persistently negative for acid-fast bacilli. It was examined for mites but none could be found. Urine was normal. Kahn's test of the blood was negative. E.S.R. was 62 mm., 1st hour. X-ray examination of the lungs showed fine mottling in the upper and middle zones and lymphatic congestion. It did not reveal the classical appearances of 'eosinophilic lung'. However, a provisional diagnosis of 'tropical eosinophilia' was made and he was given the first injection of N.A.B. 0.15 g. on 5th April, 1946. In the evening his temperature rose to 101.4. There were no other symptoms or signs of intolerance of the drug. That night the asthmatic attack was very mild and passed off soon. Next morning he looked very comfortable. His temperature was normal and cough was better. On the night following he had no attack of asthma and this was the first night since 2 months that he had had no such attack and did not get it subsequently. On 9th April, 1946, at 5 p.m., the second dose of N.A.B. 0.3 g. was given in the evening. About 3 hours later he expectorated a little blood-tinged sputum in two or three bouts of cough. At midnight he passed a motion consisting of frank blood, and four more such motions up to the next morning, each fairly large in quantity. His temperature rose to 101. The pulse rate was 96 and volume feeble and the blood pressure was 110/75. The abdomen was moderately tender all over, particularly on the right side and was somewhat rigid on palpation. Lungs were clear. The stool contained frank blood and no faecal matter. Microscopically large numbers of red blood cells were present with proportionate W.B.C. and a few epithelial cells. During the day melæna continued and he passed 12 motions of similar type containing frank blood. Marked circulatory depression occurred and the patient had to be supported with intravenous salines and glucose injections. He was given sedatives to check restlessness. Blood was examined again. It

contained no malarial parasites, its coagulation and bleeding times were normal and so was the thrombocytic count. On the following night there was intense pain in the abdomen and slight relief followed a starch opium enema. On the 11th he had 31 small motions containing frank blood and none of them showed any evidence of inflammation of the bowel. The blood pressure fell to 100/65 and intravenous transfusions had to be repeated. On the 12th the condition took a favourable turn. Motions decreased in frequency and pain abated considerably. Gradual progress was maintained for the next 3 or 4 days and things returned to normal after about 6 days. The patient had 53 bloody motions in all. They directly followed the arsenical injection though no other symptom of intolerance was exhibited. Urine was free of albumin. However, the respiratory symptoms were completely relieved and all this while the patient had no asthmatic attack. His cough also abated and the chest became clear. Subsequent blood counts were as follows :—

16-4-46 ..	Total count 16,000.	Polymorphs 28%
		Lymphocytes 40%
		Eosinophils 32%
22-4-46	Eosinophils 25%
27-4-46 ..	Total count 8,200.	Polymorphs 52%
		Lymphocytes 30%
		Eosinophils 18%

The patient was discharged on 29th April, 1946, and was instructed to report periodically, which he did. He kept completely free from respiratory symptoms for the following 6 months and did his work normally. During this period he had no abdominal symptoms, the chest and abdomen revealed no abnormality on examination and his blood counts were as follows :—

15-5-46 ..	Total count 9,600.	Eosinophils 13%
8-7-46 ..	Total count 10,200.	Eosinophils 12%

On 21st October, 1946, he got slight cough with expectoration which he attributed to taking bad ghee. There was no asthmatic attack. The chest showed a few medium-sized rhonchi. Blood counts were :—

Total W.B.C.	13,900
Differential count—		
Polymorphs	57%
Lymphocytes	10%
Large mononuclears	3%
Eosinophils	30%

An x-ray picture of the chest was again taken. It showed no abnormality. The patient was kept under observation and nothing was prescribed. The symptoms gradually abated and he kept free from them subsequently up to date.

On 9th December, 1946, he had slight cough, the chest was clear and the counts were as follows :—

Total W.B.C.	10,000
Eosinophils	18%

A check-up on 21st March, 1947, showed complete freedom from symptoms, no signs in the chest, no splenic enlargement, total leucocytes

8,500 per c.mm. and a differential count of polymorphonuclears 52 per cent, lymphocytes 36 per cent, large mononuclears 3 per cent, and eosinophils 9 per cent.

Discussion

The clinical features of this case including the paroxysms of expiratory dyspnoea with dry cough, low-grade fever, loss of weight, spasmodic signs in the lungs with a moderate enlargement of the spleen, moderate leucocytosis with high eosinophilia, *viz*, 73 per cent are highly suggestive of the presence of tropical eosinophilia. Even in the absence of typical radiological appearances, the dramatic response to arsenic confirms the diagnosis. The case exhibits a few points of interest.

Firstly, the severe hæmorrhagic complication which followed the second injection of 0.3 g. of N.A.B., 5 days later than the first dose of 0.15 g., deserves pointed attention. Slight hæmoptysis preceded the severe melæna which almost endangered the life of the patient and persisted for 3 days. This complication has not heretofore been recorded in such a frank form as it occurred in this case. Arsenic is a well-known endothelial poison and it has been observed that wall of the capillary is injured by arsphenamine as a result of which there occurs either diapedesis of blood cells through the vessel wall or frank hæmorrhage (Boyd, 1945). Hæmorrhagic encephalopathy and hæmorrhagic nephropathy have been described after its administration (Harrison, 1946). Colitis has also been observed. On post-mortem examination widespread ecchymosis and capillary hæmorrhages in all organs including the intestine have been noted. All the same such profuse melæna is not a common happening during arsenic therapy. Who has not given hundreds of N.A.B. injections to his syphilitic patients without noticing such frank hæmorrhages? This experience makes one wonder whether the eosinophilic condition had something to do with this profound hæmorrhagic reaction of the patient to a small dose of the arsenical.

Secondly, the complete amelioration of symptoms and stoppage of asthmatic attacks after the very first injection of arsenical should be noted. This patient received only 2 injections of N.A.B., first 0.15 g., and second after 5 days, 0.3 g. during April and except for a mild exacerbation in the month of October he kept completely free from symptoms in this period of one year. The leucocyte count had fallen to 8,000 with 18 per cent eosinophils nearly 3 weeks after the first injection. Eosinophils were 12 to 13 per cent in the subsequent 6 months. In October the total count rose to 13,900 with 30 per cent eosinophils and he had slight cough without any asthmatic attacks or temperature. No treatment was given and the condition settled of itself within a week's time. Eosinophils in December 1946 were 18 per cent and a check-up in March 1947 showed complete

freedom from symptoms, total leucocytes 8,500 with 9 per cent eosinophils. The usual course of arsenic suggested for the disease is 4 to 6 injections and subsidence of eosinophilia was observed by Weingarton (1943), Simeons (1943) and others after the 4th injection. This case, however, kept asymptomatic for 6 months after two small doses of N.A.B., and the slight recurrence subsided by itself. Subsequently the patient has been completely free from symptoms and eosinophilia has settled down to 9 per cent. Thus it will be observed that two small doses of N.A.B. were quite effective in checking the disease over this period of one year.

Thirdly, this case further supports the view that radiological changes in the lungs should not be insisted upon for a diagnosis of tropical eosinophilia.

Summary

In a case of tropical eosinophilia severe melæna has been reported as a complication during arsenical therapy. Follow-up of the case for one year showed that after two small doses of N.A.B. the disease was checked and no severe relapse occurred.

HETEROZYGOUS Rh TRANSMISSION IN A LARGE FAMILY WITH A CASE OF ERYTHROBLASTOSIS FOETALIS

By K. S. RANGANATHAN, M.R.C.S., L.R.C.P.

Officer on Special Duty (Blood Transfusion), Office of the Director-General, Indian Medical Service, New Delhi

A CASE of neonatal jaundice was referred to the writer on the 6th December, 1946, with the following history :—

The baby was born after an apparently normal pregnancy and labour on the 4th December, 1946, at 7-30 a.m. It was quite healthy and weighed 7½ lbs. A slight yellowish discoloration of the skin was noticed the same evening and by the next morning the jaundice was marked. An injection of mother's blood had been given. The death of the previous child from neonatal jaundice caused the prompt reference of the patient for investigation. This was the mother's third pregnancy. The first child was delivered by forceps and died within 15 minutes of delivery. The second pregnancy resulted in the birth of a full-term child in November 1945. The baby was healthy at birth and weighed 7 lbs. Jaundice appeared on the 2nd day and was complicated

by diarrhoea on the 4th day. The jaundice increased in severity and the infant died on the 9th day.

When the baby was first seen on the 6th December the skin was deeply jaundiced and shrunken, eyes tightly closed, lips and tongue somewhat dry, liver and spleen not palpable. The baby was dull and took the feeds poorly. The cry was feeble and hoarse.

Investigation.—Samples of blood were collected from the baby and its parents and from two brothers and four sisters of the mother. In addition the baby's hæmoglobin percentage was estimated and blood smears taken for examination.

The child's hæmoglobin was 80 per cent. The blood smear showed anisocytosis, poikilocytosis and polychromasia but no nucleated red blood cells. The blood belonged to group B and was Rh positive. The results of the blood grouping and Rh tests of the other members are shown below :—

	Blood group	Rh group (anti-Rh ₀ serum)
Father ..	O	Rh +
Mother ..	B	Rh -
Brother ..	B	Rh -
Brother ..	B	Rh +
Sister ..	B	Rh -
Sister ..	B	Rh -
Sister ..	B	Rh +
Sister ..	B	Rh +

Thus the father and baby were Rh positive and the mother Rh negative. The mother and child were of the same blood group B. The Rh heterospecificity of the mother and child was suggestive and so evidence for iso-immunization of the mother was looked for. The usual tests for Rh sensitization were done. For the test cells the five Rh positive bloods including the baby's were used, while the Rh negative bloods were utilized as negative controls.

The table shows the results of tests for Rh sensitization.

It will be seen that the three tests were positive against all the Rh positive bloods and negative against Rh negative bloods, thus demonstrating that the immune antibody in the mother's serum was an anti-Rh antibody. Chown's test was doubtful in one instance (no. 5) and this may probably be attributed to the test being performed with capillary tubes of unequal bore. It may be observed that the appearance of the pattern of the cell sediment in some of the tubes in the conglutination test suggested a positive test but on microscopical examination it was shown to be due to rouleaux formation.

Progress and treatment

7th December, 1946.—About 75 c.c. of blood from one of the Rh negative uncles were drawn in 10 c.c. of 3 per cent sodium citrate. The

TABLE
Tests for Rh sensitization

+ indicates presence of agglutination. — indicates absence of agglutination. ± indicates doubtful reaction.

blood was transfused through a scalp vein. After about 15 c.c. had run in, the flow of blood stopped, the needle probably having got displaced. Further attempts to needle a vein were unsuccessful. There was no reaction to the transfusion.

In spite of the small quantity of blood transfused the baby showed marked improvement. It looked brighter and took the feeds better. The jaundice cleared up within 4 or 5 days. The hæmoglobin level, however, continued to be at 80 per cent.

On the 14th December, 1946 (i.e. 10th day after delivery), samples of mother's serum and breast milk were titrated to determine the antibody content. The average titre of serum against five different group B Rh positive bloods was 16, while even neat breast milk failed to agglutinate the cells (Witebsky *et al.*, 1942 technique).

It was considered of interest to test the Rh group of the remaining brothers and sisters of the mother. Five, three brothers and two sisters, were available for study and only one of them was Rh negative. The grandmother, who was also tested, was group B Rh positive.

Further progress of the child

The general condition continued to be satisfactory and the hæmoglobin was maintained at 75 to 80 per cent. The baby had fever on the 19th and 20th (temperature 100° to 101°F.). The general condition deteriorated rapidly, the hæmoglobin dropping to 30 per cent and the R.B.C. count to 1.5 million per c.mm.

A transfusion of blood from the same Rh negative donor was attempted but only 10 c.c. could be given. A further transfusion of 40 c.c. was given on the following day. There was

marked improvement following the last transfusion. However, a blood smear taken for a study of the blood picture was reported to contain numerous B.T. malarial parasites and also nucleated red cells. There was also poikilocytosis, anisocytosis and polychromasia. The baby was promptly treated with quinine and apart from a persistent anæmia the child was otherwise well till 6th March, 1947, when last heard of. The hæmoglobin had risen to 60 per cent. Further blood transfusion was suggested but unfortunately refused.

Discussion

The first question that suggests itself is 'was it a case of congenital hæmolytic disease?' For an answer one has to take into consideration not merely the clinical picture and the hæmatological findings, but also the family history, the Rh group of the baby and its parents and the serological findings with the mother's blood.

The points in favour of the case being one of congenital hæmolytic disease are (Chown, 1944), history of death of the previous child from neonatal jaundice (Diamond and Abelson, 1945), Rh heterospecificity of the mother and baby (Polayes and Ohlbaum, 1945), presence of anti-Rh agglutinins in the mother's blood (Ranganathan *et al.*, 1946), their specificity to the baby's red cells (Wiener, 1945) and onset of jaundice on the day of birth and its progressive increase associated with anæmia. The points against are (Chown, 1944), absence of typical clinical features, enlargement of liver and spleen (Diamond and Abelson, 1945) and absence of nucleated red cells. It has to be remembered that the above are features of severe cases of erythroblastosis foetalis and that mild cases may not present the typical picture. Polayes and

Ohlbaum (1945) consider that in this disease marked polychromasia has the same significance as the nucleated red cells.

'Was blood transfusion indicated?' For an answer one could not do better than to quote Wiener (1946) who states that 'if an infant has congenital hæmolytic disease due to univalent Rh antibodies, the presence of a hæmoglobin concentration of 80 per cent is usually sufficient indication for transfusion.' If an infant has icterus gravis due to bivalent Rh antibodies (Rh agglutinins as in the present case), Wiener advocates completed exsanguination transfusion as the treatment of choice.

It is feared that malarial infection was transmitted to the baby by the blood transfusion. A careful inquiry later showed that the donor had had fever (malaria?) about 6 months previously. It is probable that the fever which the baby suffered from on the 19th and 20th, i.e. 12 days after the transfusion, was malarial and had a blood examination been done during the fever the diagnosis would have been made.

The donor in question was considered most suitable on account of his good general health and prominent arm veins. Thick blood smears taken from him on the 26th December showed no malarial parasites although the baby seems to have served as a culture medium to show up the latent malaria in him. The obvious lesson to be learnt is that donors with a history of malaria should not be accepted and that no reliance can be placed on the examination of the donor's blood to rule out malaria.

The case is of considerable interest from the genetic point of view. The grandmother is Rh positive and heterozygous (Rhrh). Twelve out of fourteen brothers and sisters were available for study and five of them including the baby patient's mother are Rh negative. The occurrence of no less than five Rh negative individuals in the same family is significant and helps to strengthen the impression that the seeming rarity of congenital hæmolytic disease in India is probably due to want of recognition rather than to lack of its occurrence. It also serves to illustrate another point emphasized by the author and his collaborators (1946) that the larger size of the average family in India may be expected to result in a larger number of affected children.

Lastly, attention may be drawn to the practice of giving the mother's whole blood to infants suffering from neonatal jaundice. That it is an improper treatment in cases of *erythroblastosis foetalis* will be appreciated from the fact that it is the maternal antibody which causes the disease and further injection of the mother's blood will only aggravate the condition.

Summary

(1) A case of heterozygous Rh Mendelian transmission in a large family with a case of congenital icterus gravis is reported.

(2) The accidental transmission of malaria by transfusion is recorded and the futility of examining blood smears to rule out malaria in donors is further confirmed.

(3) The possible danger of injecting the mother's blood indiscriminately to cases of neonatal jaundice is pointed out.

My thanks are due to Major M. H. Shah, I.M.S., Superintendent, Irwin Hospital, New Delhi, for affording facilities for investigation in the hospital laboratory and to Dr. Sher Singh, Pathologist to the hospital, for willing assistance and co-operation. My grateful thanks are due to Lieut.-General R. Hay, C.I.E., I.M.S., Director-General, Indian Medical Service, New Delhi, for permission to publish this article.

A Mirror of Hospital Practice

LOBECTOMY FOR GIANT CYST OF THE LUNG

By B. R. BILLIMORIA, F.R.C.S.

(Consulting Surgeon, Bel-air Sanatorium; Honorary Surgeon, Masina Hospital, Bombay, late Assistant Surgeon, Harefield Thoracic Surgical Unit, England)

THE interesting features of the following case merit its publication:—

Olive C., aged 18, was admitted to hospital for investigation of progressive dyspnoea. An x-ray of the chest was taken and a diagnosis was made of a right spontaneous pneumothorax. Needling of the chest showed that the pressures were +8 +3. Two hundred c.c. of air were withdrawn and the pressures reached $\pm 0 - 4$. Five days later the pressure readings were again taken and found to be +2. Four hundred c.c. of air were withdrawn and the pressures reduced to $\pm 0 - 1$. Four days later the chest was again needled and pressures found to be +2 +6.

A diagnosis of a persistent spontaneous pneumothorax was made and the patient referred to the Harefield Thoracic Surgical Unit for further investigation.

On admission to Harefield she was found to have, clinically, the signs and symptoms of a right pressure pneumothorax. Radiologically (figure 1, plate XV) the appearances were more in favour of a balloon cyst of the lung.

Fig. 1.

Fig. 2.

Fig. 3.

Fig. 4.

Fig. 5.

Fig. 6.

Fig. 1.

Fig. 2.

Fig. 3.

Fig. 4.

A bronchogram of both sides (figures 2, 3 and 4; plate XV) showed that no oil entered the cyst and on the left side there was no evidence of cyst formation and the bronchogram was normal apart from a slightly unusual distribution of the bronchi to the lower lobe.

Bronchoscopy showed that the right stem bronchus was a little widened. The orifice of the left stem bronchus was narrowed by a shift of the carina to the left.

The patient was treated expectantly at first, but in view of the progressive and disabling dyspnoea, thoracotomy was felt justifiable.

Operation.—A postero-lateral thoracotomy was undertaken through the bed of the sixth rib. An enormous thin-walled cyst was found occupying the greater part of the right chest. The cyst arose from the lower lobe and was lightly adherent to the chest wall, the mediastinum and the upper lobe. The lower lobe was emphysematous and the greater part of it was obliterated by the cyst. The upper lobe appeared normal; the middle lobe was divided by a horizontal fissure into an upper and lower segment, but was normal in other respects. The inferior and superior pulmonary veins united well outside the pericardium. A dissection of right lower lobectomy was performed. The lower lobe artery, the inferior pulmonary vein and the lower lobe bronchus were identified and dealt with, individually, in that order. The chest was closed without drainage.

She made a good recovery, and when seen in the outpatient department, three months later, was perfectly fit.

Pathological examination of the cyst showed it to be an enormous emphysematous bullous cyst.

Summary

As a rule, thoracotomy is not justifiable for emphysematous bullae as they are usually multiple and bilateral. In this case, however, progressive dyspnoea and the absence of any evidence of other cysts made thoracotomy justifiable.

I wish to thank Mr. T. Holmes-Sellers for allowing me to take charge of this patient and operate on her. I also wish to thank Dr. K. Stokes and Dr. L. G. Blair for their permission to publish this case and the x-ray plates.

IDIOPATHIC LUNG ABSCESS BURSTING INTO THE CHEST WALL

By K. M. MUCHRIKAR

Medical Officer, Dabra

A HINDU male cultivator, aged 30 years, consulted me for an operation on a big tumour which had grown over his left chest in fifteen days and which was causing stretching pain at the local site. It had also given rise to a slight dry cough for four days. There was no recent history of any acute illness and the swelling had grown gradually.

On examination, I found that the swelling was of the size of a small coconut, like a balloon distended with gas, by the side of the pectoralis muscle, very tense and slightly hot to touch. The percussion note was dull but on auscultation breath sounds were clearly heard. However, the heart sounds were accentuated over the precordia and an indefinite thrill was occasionally felt under the palm with no definite propagation.

At first sight it appeared to be like a cardiac aneurysm but because of the unusually big size and absence of other special features this diagnosis was ruled out.

A deep abscess underneath the pectoralis muscle was excluded due to the absence of dullness and fluctuation. A localized pneumothorax giving rise to such a ballooned swelling in the absence of any visible respiratory distress and expectoration was also an abnormal imagination.

Consequently an exploratory puncture was decided upon to arrive at a definite diagnosis. There was a forcible rush of air through the needle and a small streak of pus was left near its tip.

The next day, the patient was screened and, to one's astonishment, the radiologist reported a big abscess on left lung with a fluid level (left upper zone).

(a) Examination of blood.—Leucocytosis 21,200, poly 89 per cent, lympho 11 per cent.

(b) Examination of pus (slide).—Pus cells many. No micro-organism seen.

Three days later, the abscess suddenly and spontaneously burst at midnight, while the patient was asleep. This evacuation probably occurred, through the exploratory puncture, during some strain of coughing in sleep, and resulted in complete disappearance of the tumour. During this period the patient was having a little rise of temperature between 99 and 100°F., and the slight dry cough was persistent.

The screening of the chest after bursting of the abscess: Abscess on left upper zone, lung markings considerably increased, no fluid level seen.

After ten more days the patient was fit to go home.

Interesting points

1. All the conditions under which a lung abscess generally forms were more or less absent. Pulmonary distress was almost nil to account for its development.
2. There were no complications or sequelae and the recovery was quick and eventful.
3. There was no toxæmia at any stage of illness, nor any marked deterioration in health.

With kind permission from Dr. B. Sahai, M.D., Superintendent, J. A. Hospital, Lashkar (Gwalior).

A CASE OF APPENDICITIS AND CON- GENITAL INGUINAL HERNIA

By A. D. BHANDARI

Medical Officer Incharge, District Hospital, Bareilly

RAMPAL, aged 2 years, was admitted on 22nd January, 1947, in the District Hospital, Bareilly. The mother stated that when the child was 6 months' old she noticed a swelling in the right inguinal region which used to swell more whenever the child cried. It was noticed that the swelling was reducible. During the last six months she observed occasional sickness and fever which she attributed to teething.

Condition on admission.—Emaciated, peevish child, much rundown, tendency to vomit after feeds and slight fever. There was complete inguinal hernia on the right side. Hernia was reducible and there was marked tenderness in the hernial region.

Under ether anaesthesia the usual hernial incision was made. On exposing the sac it was found to contain omentum which was adherent to the walls of the sac, caecum and appendix which was about 2 inches long and inflamed. Appendectomy was done and after the usual hernial repair the wound was closed. The child was given 400,000 units of penicillin injections in divided doses for 6 days. He made an uneventful recovery and was discharged cured on 7th February, 1947.

It appears that this child got mild attacks of appendicitis not amounting to suppuration. Size of the appendix was fairly big for a child of his age.

GAS GANGRENE

By S. K. ROY, B.Sc., M.B.

Medical Officer, Barabil Hospital, Bara Jamda, Singhbhum District

BHUBNA, Hindu male, age 55, occupation gardener, reported to the hospital on 9th October, 1946, with a small sloughing ulcer on the dorsum of the middle finger, left hand. Duration of the ulcer two days. Complained that during the last twelve hours the oedema had spread from the hand up to the lower part of the arm.

I examined and found a sloughing ulcer present on the dorsum of the interphalangeal joint of the left middle finger. Fair amount of oedema of the left hand, forearm and lower half of the arm. It pitted on pressure. Pulse 120 p.m., resp. 24, temp. 101°F., tongue—coated, bowels—not moving.

Blood picture.—Hb. = 35 per cent, R.B.C. = 2,600,000 per c.mm., W.B.C. = 16,000 per c.mm.

The ulcer cleaned and dressed. Put on a course of sulphathiazole, 4 tablets stat and 2 tablets every 4 hours.

Next morning, i.e. after 24 hours, the oedema spread up to the left side of the chest, front and back. The swelling of the hand, forearm and arm also increased to a great extent and angry

looking. The lower half of the arm, forearm and dorsum of the hand were covered with blebs, containing serosanguineous fluid. Some of the blebs on the dorsum of the hand along with the underlying soft tissue started sloughing. Webs of the fingers were covered with sloughing ulcers. Pulse 132 p.m., temp. 102.4°F. Patient rather toxæmic. Started a course of penicillin at 11 a.m. on 10th October, 1946, initial dose 25,000 units and subsequent doses 12,500 units every 3 hours intramuscularly. On 12th October, 1946, the temperature came down to normal and the swelling started subsiding. On 13th October, 1946, two bottles of penicillin (100,000 units each), which were 5 months outdated but kept all the time in refrigerator were given in 5 doses at 3 hourly intervals. General condition of the patient seemed to improve. No more penicillin being immediately available, sulphathiazole was stopped and the patient was put on a course of sulphadiazine 1 gramme in 4 c.c. given intramuscularly thrice daily for 3 days, and 25 per cent 25 c.c. glucose solution intravenously twice daily, as the patient was very weak and prostrated.

The hand, forearm and the arm were being dressed with acriflavine after hot bath (eusol, later on saline). Later on the dressing was vaseline gauze.

During the course of the disease the inflammatory swelling of the hand and the forearm was so great that formation of deep pus was apprehended, the presence of fluctuation being vague and indefinite, due to enormous oedema. The hand and forearm were tapped in several places to localize pus, but it was absent.

The patient was cured and discharged from the hospital on 19th November, 1946, with slight atrophy of the left forearm and deficient movements of the fingers and the hand.

Conclusion

Sulphathiazole did not appear to check the progress of the disease during the first day. Penicillin was effective in the next 48 hours. Treatment was completed with further sulphadiazine injections.

I wish to express my thanks to Dr. Frank McCay, M.A., M.D., Chief Medical Officer, Messrs. Bird & Co., for kindly allowing me to publish this case.

Therapeutic Notes

NOTES ON SOME REMEDIES

X. ANTIMONY AND ITS DERIVATIVES (PART I)

By R. N. CHAUDHURI, M.B., M.R.C.P. (Edin.),
T.D.D. (Wales), F.S.M.F.

Professor of Tropical Medicine, School of Tropical Medicine, Calcutta

ANTIMONY has been used in medicine since very early times and became very popular in the sixteenth and seventeenth centuries when

tartar emetic (potassium antimonyl tartrate) and a number of other compounds were freely prescribed for diseases like syphilis, leprosy, plague and ague. Owing, however, to indiscriminate use so much harm was done that it fell into discredit and was prohibited in many places; the graduates in medicine of Heidelberg, for instance, were required to take an oath never to use it. In the early part of the present century it occupied an unimportant position in the list of drugs, being used chiefly for its expectorant action in the early stages of acute bronchitis when the secretion of bronchial mucous membrane is scanty. The revival of antimony dates from 1908 when it was found to have a remarkable effect on trypanosomes in animals. In the following year Kerandal reported having successfully treated himself for trypanosomiasis with intravenous injections of tartar emetic after atoxyl had failed, and in 1913 Vianna and Machado in Brazil reported the cure of mucocutaneous forms of leishmaniasis. In 1915 Di Cristina and Caronia successfully treated infantile kala-azar prevalent in the shores of the Mediterranean, and in the same year their results were confirmed by Rogers and Muir in India. Thus was found a cure for a disease which was once regarded as inevitably fatal and in which it is now possible to predict a cure in over 90 per cent of the cases.

This success with kala-azar led within a short time to another discovery, *viz.*, a cure of schistosomiasis, a disease in which no drug was known to have any effect thirty years ago. The main credit belongs to J. B. Christopherson who, while treating a case of kala-azar in the Sudan with tartar emetic, noticed improvement in the symptoms of bilharzial disease from which the patient also suffered. The beneficial effects of this method of treatment have since been abundantly confirmed except when the disease is very chronic and advanced.

Antimony has also proved more or less successful in granuloma venereum, lymphogranuloma inguinale and a few other affections which will be mentioned later in this article.

Discovery of new compounds

In the treatment of kala-azar the antimonyl tartrates were found to possess certain disadvantages. Being very toxic, not enough of the drug could be administered at a time, hence the course of the treatment was prolonged. Moreover, the fact that it can be administered only intravenously, makes it unsuitable for children, and many cases also are very resistant to it. In the search for a better drug certain pentavalent antimony compounds have been produced; these are salts of para-aminophenylstibinic acid or substitution products of the same. These compounds are much less toxic and more effective than tartar emetic, reducing the average duration of treatment from 2 to 3 months to about 2 to 4 weeks and giving more cure rates

and fewer relapses; also some of them are suitable for intramuscular injection. But it should be noted that they are not always superior to the trivalent compounds (of which tartar emetic and foudadin are examples) in conditions other than kala-azar.

The antimony compounds for therapy may thus be divided into two classes—trivalent and pentavalent. A host of preparations are on the market, and the following list, though not complete, includes many of them.

I. Trivalent compounds

1. Antimonyl tartrates (potassium or sodium).
2. Fouadin (neoantimosan).
3. Anthiomaline (May & Baker).

II. Pentavalent compounds

1. Stibosan (von Heyden 471).
2. Neostibosan (von Heyden 693 B).
3. Urea stibamine (Brahmachari) and homologues, *e.g.* aminostiburia (Union Drug Co.), and stiburamine (B. C. P. W.).
4. Solustibosan (Bayer 561) and Stibatin or sodium antimony gluconate (Glaxo).
5. Neostam or stibamine glucoside (B. W. & Co.).

Dosage and methods of administration

Most of the compounds are supplied in sealed ampoules in powder form or in solution ready for injection. The powder is freshly dissolved in sterile distilled water at the time of injection as the solutions are liable to undergo chemical changes on keeping. The dosage varies with the toxicity of the individual drugs, but treatment should always be commenced with small doses, gradually increasing the subsequent doses so that tolerance may be established. In debilitated patients the dose is reduced, but children tolerate antimony better than adults and require relatively larger doses. The total amount required of a drug to cure varies in different diseases and often in the same disease according to the condition of the patient. Most of the drugs are given intravenously, some are designed for intramuscular injection, while others can be given in both ways. Tartar emetic specially and to a less extent some of the pentavalents are irritant to the subcutaneous tissues, and it is most important that the needle of the syringe is actually in the vein before the injection. The injections are given at slow rate on consecutive or alternate days. They should not be given on a full stomach for fear of causing nausea and vomiting, and the patient should remain in bed for a while after the injection. Treatment, once commenced, must not be interrupted unless for grave complications, *e.g.* pneumonia, severe dysentery, jaundice, nephritis and hæmorrhage, and the aim should always be to give the full course, otherwise there will be a

relapse. Pregnancy is not a contra-indication for its use.

The dosage, etc., of the commonly used drugs are summarized in the table :—

of temperature after each injection. The febrile reaction may be due partly to the water used in making the solution, and it is always well to use fresh supply of distilled water. By careful

TABLE

Drug	Initial dose	Maximum dose	How given	Percentage of antimony	Frequency of injections	REMARKS
Antimony potas- sium tartrate.	$\frac{1}{2}$ gr.	2 to $2\frac{1}{2}$ gr.	I.V.	36	Alternate days	Used as 1 to 2% solu- tion.
Antimony sodium tartrate.	$\frac{1}{2}$ gr.	2 to $2\frac{1}{2}$ gr.	Do.	37.5	Do.	Do.
Fouadin ..	1.5 c.c.	5 c.c.	I.M.	13.5	Do.	Supplied in ampoules of 7% solution.

Second injection—0.10 gm.

Third injection—0.15 gm.

Subsequent injections—0.20 gm.

Children :

Maximum dose—0.15 gm.

Infants :

Weight less than 20 lb.—maximum dose 0.10 gm.

† Adults : 15 to 20 c.c.

Children : 10 to 15 c.c.

Infants : 5 to 10 c.c.

Mode of action

After injection antimony is quickly absorbed and evenly distributed in the body but is almost completely eliminated in two or three days, so that it never attains a high concentration in the blood. How it acts is not known, but in the protozoal diseases its action is certainly not a direct one. In schistosomiasis antimony appears to have a direct action on the adult parasites and to a less extent on the eggs. Fairley believes that it acts selectively on the reproductive organs of the female bilharzia and this brings about, firstly, the shrunken appearance of the egg and, secondly, cessation of egg-laying capacity (Manson-Bahr).

Toxic effects

After even a small therapeutic dose of tartar emetic certain toxic symptoms are to be expected. Immediately after the injection there is often a fit of coughing with, it may be, a feeling of constriction in the chest. Headache, nausea and vomiting may follow. In patients with only slight or no fever, febrile reactions are common; in some cases fever and rigors occur after the first injection, or there may be a temporary rise

regulation of the doses the toxic effects are abolished or reduced and tolerance is quickly established, but certain races are unduly susceptible to antimony; for instance, the Sudanese do not stand the tartrates well. Among the late symptoms may be mentioned diarrhoea, joint and muscular pains, jaundice and severe lung complications such as broncho-pneumonia.

With the pentavalent compounds these complications are rare. In a few cases anaphylactic symptoms occur, these set in suddenly after a few injections, especially when the injections have been rather widely spaced. The patient's face becomes puffy, the voice husky and an urticaria rash may appear all over the body. There is difficulty in breathing, the pulse is imperceptible and the patient may even go unconscious for a few minutes. Recovery, however, is rapid and is hastened by an injection of adrenaline ($\frac{1}{4}$ to $\frac{1}{2}$ c.c.). Another complication that may occur is hæmorrhage from the gums, nose and stomach.

If severe toxic symptoms arise, the drug should be temporarily discontinued; after an anaphylactic shock the best course is to employ another compound and to begin with very small doses.

PROTEIN DIGESTION RESTORED BY BOVRIL

Conclusive result of medical experiments

In many illnesses, when gastric secretion is impaired and is deficient in hydrochloric acid, Bovril corrects this condition by restoring the normal volume and activity of the gastric juice, thus aiding the peptic digestion and absorption of protein foods.

In 1911, the late Professor Thompson, of Dublin, established that Bovril had the power of ministering to nutrition by the assistance it gave to the assimilation of other foods. Recently a remarkable series of experiments has been conducted at an English University. A group of medical students volunteered to undergo the unpleasant experience of allowing the passage of an oesophageal tube into the stomach so that accurate studies might be made of the effect of certain beef preparations. One of the substances investigated was Bovril.

As a result of these experiments (described in detail in the *British Medical Journal* of August 28th 1937) Bovril emerged as 'the most effective stimulant.' Briefly, it was proved that Bovril increased the supply of gastric juices where there was a deficiency and restored it to normal. It is an accepted medical fact that people of sedentary habits generally suffer from a lowering of the essential gastric activity; Bovril rectifies this and, by facilitating the digestion of proteins, enables full nourishment to be gained.

Everyone, therefore, who is run down through strain or illness, or who feels in need of extra strength to cope with the demands of modern life, should take a cup of hot Bovril daily. It is a delicious and stimulating way of keeping fit and strong.

BOVRIL STIMULATES DIGESTION.

IN THE TREATMENT OF PEPTIC ULCER

Cal-Bis-Ma provides an efficient measure of prophylaxis in the treatment of peptic ulcer, effectively neutralising excess acidity—a paramount necessity if a re-occurrence of the trouble is to be avoided. Cal-Bis-Ma has definite protective and sedative action upon the mucosa of the digestive system. The preparation is extremely palatable, which simplifies its administration to children and adults.

B.D.H. MALE SEX HORMONES

Testosterone Propionate B.D.H. Methyl-testosterone B.D.H.

Androgen therapy is now established as the most satisfactory method of correcting hypogonadism and retarded sexual development in the male: provided treatment is instituted sufficiently early normal development can generally be produced by this means. Impotence, loss of libido and other manifestations of defective testicular activity, though they respond less certainly to androgen therapy, are further indications for its use.

Testosterone Propionate B.D.H. is the preparation of choice; administered by intramuscular injection it is approximately five times more effective than the same dose of methyl-testosterone by mouth. Tablets of Methyl-testosterone B.D.H. will be found useful, however, for the treatment of minor states of testicular hypofunction or for supplementing treatment by injection.

Stocks of B.D.H. Male Sex Hormones are held by leading chemists, and full particulars are available from—

WATSON X-RAY EQUIPMENT

gives unfailing service because....

- 1 it is designed by men of wide experience in every aspect of the electrical engineering involved, and possessing a practical knowledge of radiological requirements.
- 2 no design is based upon empiricism; the extensive research facilities of the G. E. C. Research Laboratories are employed to prove new theories—to investigate new methods and materials, and thus promote progress.
- 3 manufacture is conducted at Watson's Wembley factory by the aid of the most advanced precision machinery. Special jigs and tools ensure uniform accuracy and interchangeability.

BY APPOINTMENT
MANUFACTURERS OF
ELECTRO-MEDICAL
APPARATUS TO THE
LATE KING-EMPEROR
GEORGE V

4 tests at every stage of manufacture reduce the incidence of faults to the minimum. Nothing is allowed to leave the factory until it is as perfect as skill and knowledge can make it.

5 installation and servicing is carried out by fully-trained engineers most of whom have devoted the whole of their working lives to x-ray work.

Indian Medical Gazette

JULY

THE PASSING OF THE I.M.S.

Before these lines appear in print, in a delayed issue of this journal, a great service will have passed away.

THE BEGINNING

THE beginning of the Indian Medical Service can be traced to the 'Surgeons and Barbars' engaged by the East India Company for their ships, warehouses and factories in India and in the Far East. It was then a service as much for the Far East as for India.

The Company's first fleet sailed from England for the East in December 1600. It consisted of four ships. To each ship were appointed 'Surgeons twoe and a Barbar' (this journal, vol. XXXV, 1900; Crawford, D. G., *History of the Indian Medical Service, 1600-1913*, Thacker, Spink & Co., Calcutta, 1914).

For shore duties the surgeons were allotted to the various establishments: Bombay, including Surat and the West Coast up to Persia; Madras, including the East Coast; and Bengal, including the Bay.

Associated with this period there are several well-known names. The first one deserving mention is that of

Surgeon-General John Woodall

who in 1614 was 'sworn to provide competent surgeons and to fit up their chest properly'. He was practising in Wood Street, London, had made a name for himself in curing plague, had a secret remedy of his own called *aurum vite*, was a member of the London Company of Barbar Surgeons and was Surgeon to St. Bartholomew Hospital.

In the following year he was charged with gross abuses:

'Mr. Woodall's great abuses in the Chirurgeon's chest, putting divers boxes of one simple, whereas he writeth in their superscriptions to be diverse; drugs rotten, unguents made of kitchen stuff. Boys that have no skill thrust into places of chirurgeons. He is to be accounted guilty of the death of so many men as perish through his default'.

Obviously the complaint was not well founded. The Surgeon-General remained. In 1618 his salary was increased from £20 to £30 a year.

The second name is that of

Dr. Gabriel Boughton

of the Bombay establishment. His professional skill and loyalty to the Honourable Company are well known to several generations of school teachers and their pupils in India. He was stationed at Surat and was

sent for by the Mughal Emperor Shah Jahan to treat his daughter Jahan Ara who had been badly burnt. He cured her and refusing all personal favours asked for and obtained concessions in trade for his masters of the Honourable Company. Later he cured a lady of Prince Shuja's harem at Rajmahal and obtained further concessions in Bengal.

(As a matter of fact the stories are myths. Dr. Boughton was nowhere near Agra or any other royal residence near Surat when the Princess got burnt. Nor was he anywhere near Rajmahal when further concessions were obtained.—Crawford, *loc. cit.*)

The Princess had been burnt while attempting to help a dancing girl of the palace, whose clothes had caught fire, and was treated and cured by *Hakim* Anitulla of Lahore. The dancing girl died. This happened in 1643-44. Boughton's mission went to Agra in 1645.

The factory at Balasore made possible by the supposed further concessions had been established in 1633, 12 years before Boughton went to Agra.

The fact that these stories gained currency within 20 years of Boughton's death points to a widespread belief in Boughton's professional skill which must have been of a high order.)

The third name is that of

William Hamilton

who came out to India as Surgeon of the frigate *Sherborne*. He deserted on arrival in Madras, reached Calcutta and found employment in the establishment there.

The famous Embassy to Delhi started from Calcutta in 1714 with Hamilton as medical officer. Its object was to obtain concessions from the Mughal Emperor Farakh Siyar who had been in Bengal as a Deputy Governor of the Emperor. It was hoped that he would be influenced through his courtiers and officers of the household.

Hamilton cured the Emperor of 'swellings in the groin' which were preventing a marriage. The Emperor was so pleased that he wanted to keep Hamilton at Delhi for good. The latter however obtained leave to go to England. He died before leaving Calcutta and Farakh Siyar sent down a special messenger with an inscription for the tombstone and, incidentally, to confirm the death. The inscription, in Persian, is translated as follows:—

'William Hamilton, Physician, Servant of the English Company, who had gone along with the English Ambassador to the Illustrious Presence and had raised his name high in the four quarters by reason of the cure of the King of Kings, the Asylum of the world, Muhammad Farakh Siyar, the Victorious, with a thousand difficulties having obtained, from the Court of the Asylum of the world, leave of absence to his native land, by the decree of God on the

4th December, 1717, died in Calcutta, and in this place was buried.

The English inscription on the tombstone is : 'Under this stone lyes the Body of William Hamilton Surgeon who departed this life the 4th December, 1717. His Memory ought to be dear to his nation, for the credit he gained ye English in curing Ferrukseer, the present King of Indostan of a malignant distemper by which he made his own name famous at the Court of that Great Monarch; and without doubt will perpetuate his Memory, as well in Great Brittain as all other Nations in Europe'.

Hamilton was buried in Calcutta in the old churchyard in which later was built St. John's Church. At the time of clearing the ground the forgotten tombstone, fallen and buried under earth with the passage of some 70 years, came to light. It was, then, set up in the tomb of Job Charnock, the founder of Calcutta. This tomb is situated in the north-west corner of the ground of St. John's Church, Calcutta.

William Hamilton was a bold medical man and the distemper he cured was probably a hydrocele which prevented a marriage.

A writer of a comparatively recent period has made a 'Scotch Surgeon Gabrail Hamilton' cure the Mughal Emperor. Such can be the general information on matters Indian, of even recent British writers. (*The Seven Cities of Delhi* by Gordon Risley Hurn, R.E., London, Thacker & Co., Calcutta, Simla, Thacker, Spink & Co., Bombay, Thacker & Co., 1906.)

The fourth name is that of

John Holwell

an Irish born son of a London merchant and grandson of John Holwell, Royal Astronomer, a noted mathematician.

He was eighth on the list of 11 members of the Council of Fort William in 1756. When Calcutta was attacked by Seraj Uddola, of these 11 members, 4 were not in Calcutta at the time, 4 including Drake, the Governor, fled to the ships and 3, Pearkes, Holwell and Eyre, remained at their posts till the fall of the fort. Pearkes made his escape after the surrender. Holwell and Eyre were among those who were confined for the night in the Black Hole. During the night Eyre died. Holwell only remained.

He had been elected Governor as soon as the flight of Drake had become known. The gate towards the river, then, had been closed to prevent further desertion and a council hastily summoned. Pearkes the senior-most member had waived his right in favour of Holwell who thus had become the Governor and the Commander-in-Chief.

Prior to being a member of the Council Holwell had been an ordinary member of the service and had effected noteworthy improvements in sanitation and suggested reformation in the Collector's Court in Calcutta, while on leave in England. On the acceptance of the

suggestion by the Court of Directors he himself had been nominated to be the Collector in Calcutta. He had then returned to Calcutta in 1752, as a covenanted civilian, twelfth in the Council.

Not counting Holwell, there were 6 medical officers stationed in Calcutta at the time of its capture. Of these only one was not in the Fort. He,

William Fullerton,

fifth on our list, was on duty with the women, children and others on board the ships.

He had been Second Surgeon in succession to Holwell for over 10 years when Calcutta fell.

He made money in Calcutta in business 'speculating heavily and successfully in salt-petre in Bihar'.

He was in Bihar when the 'English *sipahis*' siding with the Emperor's Governor who had revolted were completely defeated on 9th February, 1760, at Mohsinpur near Patna, by the Emperor's army. All the English officers with the *sipahis* were killed. Fullerton then assumed command and the remnant of the party succeeded in making good their retreat to Patna. At Patna they were besieged. Fullerton made the besiegers retreat with considerable loss to them.

Fullerton knew the vernacular well and 'associated with native gentlemen much more than was usual among the English in Bengal'. He seems to have got mixed up a good deal 'in native intrigue' also. When he went on leave the Governor of Bengal wrote :—

'Mr. Fullerton is a great Bane to Society, and the Company's service; so much is said of him that he may not on any account be suffered to return'

In spite of the Governor's displeasure Fullerton returned and played a lucky rôle in the Patna massacre on 5th October, 1763, in which all other Britishers captured in a previous battle were murdered.

Later, in 1764 he was the interpreter in an enquiry into the conduct of Nanda Kumar whom the Commander-in-Chief wished to remove from the Nawab's service, on a charge of disaffection. He did not press home certain evidence with the result that the enquiry ended inconclusively. He was censured. ' . . . however as the Board do not suppose that his conduct could have proceeded from bad design but from inattention, they pass over with censure what must otherwise have called for the most exemplary severity'. Fullerton resigned and left.

(How an interpreter could press evidence home is not understood in the light of the present legal procedure.

Incidentally, later, Nanda Kumar was tried and hanged. Probably the interpreter then employed knew how to press the evidence home.)

Fullerton was a clever man of affairs with plenty of initiative. Besides, he was the first

member of the regularly constituted Indian Medical Service. In associating with 'native gentlemen' he was nearly two centuries ahead of his countrymen.

REGULAR CONSTITUTION

On 20th October, 1763, by orders passed in *Fort William*, individual medical officers serving in the Bengal Presidency were combined with effect from 1st January, 1764, into the Bengal Medical Service, with fixed grades and rules for promotion. Madras and Bombay medical services appear to have come into existence about the same time.

Some officers held double lower ranks simultaneously for several years, one for medical work and another for general military duties. Ultimately they made their choice for the promotion to higher ranks.

The military rank, however, did not count much those days. It was 'but the guinea's stamp'. The pay too was little more than pocket money. The real gain to most came from private trade and to some from private practice.

The real rank was the position amongst the Company's officers, which was pretty high. The relative precedence was as follows: (1) the Agent of the Area; (2) the Accountant; (3) the Storekeeper; (4) the Purser Marine; (5) the Secretary; (6) the Surgeon; (7) the Steward; (8) the General Body of (i) merchants, (ii) factors, (iii) writers, and (iv) apprentices. (The Chaplain when present ranked third.) From the last category, the general body, rose, at a later period, the steel framework of the Indian administration, the I.C.S.

DUTIES, ETC.

Before 1788 medical officers with the troops were hardly considered officers. They started as Assistant Surgeons and were 'appointed to be officers', later.

The Company's army had by now greatly increased. It defended the property and privileges of the Company and also aided neighbouring chiefs and princes for a consideration.

The civil and military branches of the I.M.S. were united and separated again several times. The military duties were those performed in India at the present moment by the newly constituted I.A.M.C. (Indian Army Medical Corps).

The civil duties once upon a time included everything falling under Medical Relief, Public Health, Prisons, Forensic Medicine, Medical Education, Medical Research and Research on allied subjects. The numerical strength of the civil branch at this time was greater than that of the military branch. All civilians, however, had to start as soldiers.

The civil branch ultimately was placed under the D.G., I.M.S. and the military under the D.M.S. (Director of Medical Services). The latter director for a long time belonged to the R.A.M.C. (Royal Army Medical Corps); the

British Service for duty with the British Troops. Later he was selected from the R.A.M.C. and the I.M.S. (military branch) alternately.

In addition to the ordinary duties which fall within the scope of medical men, the Service has also supplied Post Masters, Cotton Agents, Mint Masters, Superintendents of Schools of Arts, Political Agents and Conservators of Forests. Chemists, Botanists and Zoologists there have been many. The Service played an important part in the organization of Forest and Veterinary Departments.

The versatility within the limits of medical duties, efficiency and physical fitness of the early I.M.S. officers cannot be illustrated better than by giving a brief account of

Frederic John Mouat.

Born 1816. Educated in London, Edinburgh and Paris. M.R.C.S. in 1838. M.D. Edin. in 1839. One of the Original Fellows of the Royal College of Surgeons, London, in 1844.

Entered I.M.S. as Assistant Surgeon in 1840. Surgeon in 1853. Surgeon Major in 1860.

Professor of *Materia Medica* in the Calcutta Medical College in 1841; also Secretary from 1841 to 1851. Professor of *Medicine* in 1849. First Physician *ex-officio* of the Calcutta Medical College Hospital in 1853.

I.G. of Jails in Bengal, 1855 to 1870. Deputed to visit the Andaman Islands to choose a site for a convict settlement which later became Port Blair. Wounded in the mouth and had two ribs broken in a fight with the Andamanese.

Retired from the I.M.S. and was appointed one of the Medical Inspectors of the Local Government Board in England in 1874. Held this office until 1887, for 13 years.

As a Medical Inspector, in connection with the restoration of the Church of St. Peter in the Tower of London, with other officials of the State, was present at the removal of the pavement, and identified the skeletons of the following:—

1. Queen Anne Boleyn, once the beloved Queen of King Henry VIII and beheaded by his orders, mother of Queen Elizabeth the Great in whose reign the East India Company and the I.M.S. began life.

2. Lady Rochford, Companion to Queen Katharine Howard, beheaded by the orders of the same King.

3. Duke of Somerset beheaded in the reign of Edward VI.

4. Duke of Northumberland, father-in-law of Lady Jane Grey, executed in the reign of Queen Mary.

5. Duke of Monmouth, natural son of Charles II, executed by the orders of James II.

The skeleton of Katharine Howard, also executed by Henry VIII, was not found.

(After all, what was going on in England under the Tudors and the Stuarts was not different from the intrigues of the then Imperial,

Royal and Princely India : only occurring in a vaster area, in contiguous territories and in the midst of a larger population it created more confusion at times.

The confusion would have been worse if the masses, the peasantry which is India, had taken part in it. The peasantry did not and could not take part because it did not become aware of the political changes until after the events, thanks to the system of payment of land revenue in India.

The land revenue in India has been paid, since times immemorial, by the villagers at the same central offices, the *Tahsils* of Northern India—from *hasil* = gain—to the same local officials who have stamped the receipts with the same official stamp. The villagers did not become aware of a change of power until many years after the change had taken place. Of the impending changes they knew nothing.)

Died in London in 1897. A life well lived indeed.

These accounts of the lives of Service men culled from the monumental work of

Colonel D. G. Crawford, I.M.S.
(Bengal Service, Retired List);

the historian of the Indian Medical Service, are not likely to be well known to the younger generations of the members of the Service. Much less are they likely to be so known to non-Service men who now have been handed the torch of medical knowledge lit over three centuries ago and kept alight nearly all this time by the I.M.S.

The latter day accomplishments of the Service are matters of international fame in medicine. A few of the many names so known to fame are :—

1. Ross, R.
2. Rogers, L.
3. Harvey, W. F.
4. Cunningham, J.
5. Christophers, R.
6. Knowles, R.
7. McCarrison, R.
8. Sinton, J. A.
9. Sutherland, W. D.
10. Megaw, J. W. D.
11. Anderson, L. A. P.
12. Tarapore, P. K.
13. Chopra, R. N.
14. Iyengar, K. R. K.
15. Sokhey, S. S.
16. Bhatia, S. L.

Most of them are alive and well, and two are still serving as non-I.M.S. officers.

Indians were admitted to the Service a long time ago but numerically and in advancement they failed to attain equality with the Britishers up to the last. Even their emoluments decreased during the last 27 years or so, through two revisions of pay and allowances. The military traditions, however, established a comradeship

which worked very well indeed in matters of duty and even of social intercourse.

THE END

After the military branch had been absorbed completely into the I.A.M.C. during the last few months a very much thinned civil branch remained until the 15th August, 1947. Many of those who before this date had signed their own deed of abdication were not really sad. They would not have desired a great service to have survived its greatness.

The Service was great partly from definition, partly from exclusion, partly from martial merit and partly from professional merit. The first two privileges wore out during the two World Wars, against the onslaughts of increasing forces of democratization. The third privilege has been inherited intact by the youthful offspring of the Service, the I.A.M.C. The last privilege was born to flourish, to mature, to go to seed and, thus, to multiply 'an hundred fold' on ground made good by human evolution. The sower came out to sow and he has sown. He has now departed. The I.M.S. has not died : it has been fulfilled.

The end was not unexpected, though not all who came to this prognosis looked upon it as a fulfilment. Long before the World War II, during the Annual Service Dinners in London, a swan of ice-cream, representing the last swan song of the Service, and an elephant of ice, representing the melting Indian Empire, taken round on trolleys, had saddened the hearts of the diners, rendered naturally heavy at the stage of nuts and wine.

THE SHAPE OF THINGS TO COME

When the prejudices and preferences of to-day have ceased effervescing the service which will ultimately take the place of the I.M.S. will not be much different from it. After all, professional efficiency, organizing capacity and administrative ability of higher order are more likely to be found amongst disciplined medical men who are physically fit, who travel and who enjoy a certain measure of leisure. The future is only the past entering through another door.

I.M.S. FAREWELLS AND RETROSPECTS

ON p. 438 in this issue will be found a letter of retrospect and farewell which Lieut.-General R. Hay, C.I.E., K.H.P., I.M.S., Director-General, Indian Medical Service, has addressed to all officers of the Indian Medical Service on the eve of its dissolution on 15th August, 1947. We wish him also farewell.

As the General is leaving India as a perfectly fit soldier of Category A, we further wish him success in his future undertakings and hope that he will be on the list of the 'Distinguished Contributors' to the *Indian Medical Gazette* for a long time to come.

On pages 420 and 422 will be found accounts of the first I.M.S. dinner in London held fifty years ago and of the last dinner held this year.

THE NEW INDIAN CHIEF OF STATE MEDICAL AND HEALTH SERVICES IN INDIA

ALL concerned have been notified that with effect from the 15th August, 1947, the posts of Director-General, Indian Medical Service, and Public Health Commissioner with the Government of India will be abolished and a new post

of Director-General of Health Services created. All communications intended for
The Director-General, Indian Medical Service
or

The Public Health Commissioner with the
Government of India
should in future be addressed to
The Director-General of Health Services, New
Delhi.

We offer our hearty congratulations to
Dr. Jivraj N. Mehta, M.D. (Lond.), M.R.C.P., the
first Indian occupant of this post.

Special Article

SCIENCE AND INTERNATIONAL GOODWILL

By S. L. BHATIA, C.I.E., M.C., M.A., M.D. (Cantab.),
F.R.C.P. (Lond.), F.R.S. (Edin.)
COLONEL, I.M.S.

Inspector of Civil Hospitals, Assam

(A speech delivered at the U.N.E.S.C.O. Celebrations
in Shillong, Assam, on 29th November, 1946)

WHAT is this diabolical thing, called science? This question has been repeatedly asked by men all the world over, ever since a couple of atom bombs found their way over Japan in 1945, and their consequences and repercussions were brought home to us in a most dramatic fashion.

Science is knowledge primarily based on facts, which are ascertained by observation and experiment. From these facts inferences are drawn and general laws and principles are formulated, into which these facts can be fitted in. 'Facts are the air of a scientist' said Pavlov the celebrated Russian physiologist. 'Without them you never can fly. Without them your theories are vain efforts'. Science concerns itself with the discovery of truth. The social importance of science is due to the fact that it enables us to manipulate and gain mastery over nature.

As a factor in human life, the rôle of science is very recent. It began with Galileo, and has existed for some 300 years. During the first half of that period, it remained a pursuit of the learned, and did not affect the thoughts or habits of ordinary men. It is only during the last 150 years that it has become an important factor in determining the everyday life of the people. But these 150 years of science have proved more explosive than 5,000 years of pre-scientific culture. Scientific knowledge advanced rapidly throughout the 17th, 18th and 19th centuries. But it was in the 19th century that it really began to affect the lives of men.

Science may be divided into two groups :—

(a) The physical group comprising physics and chemistry. It deals with properties of matter apart from life.

(b) The biological group comprising botany, zoology, physiology, etc. Medicine is included in this group. It deals with phenomena of life associated with matter.

The effect of biological science on human life has been very small so far. There is of course Darwinism and the idea of evolution, and these have served as arguments in favour of nationalism. We may, however, expect greater effects from this in the near future; for instance, there are great potentialities in Mendelism and the study of heredity, so far as the future of the human race is concerned. Hitherto the most effective of the biological sciences has been medicine, on account of its influence on the health of the community as well as the individual. It has taught many potent means of preventing and curing quite a number of diseases and thus raising the standard of health.

But it is the physical sciences which have had the greatest effect on the affairs of mankind. It is they that brought about industrial revolution in the 19th century. One of the effects of this industrial revolution is to make the entire world an economic unit. Another effect of industrialism is to increase the productivity of labour, and thus make more luxuries possible. In England, its early effects were an increase in population with a lowering in the standard of living. This was followed by a wave of prosperity, when the wages increased and the hours of work diminished, accompanied by expansion of trade.

Modern industrialism produces a struggle between nations for markets and raw materials. This produces international competition. The men of science in different national groups continually produce more and more elaborate methods of attack and defence. It is undoubtedly true that it is science mainly that has determined the importance of raw materials in international competition. Coal, iron and oil are the basis of power and of wealth; they are also indispensable in the art of war.

Science has been a great stimulus to the growth of nationalism. Nationalism has grown

rapidly because of the increase of large-scale organization, in which science has materially helped. Without railways, telegraphs, telephones and the radio, the control from the centre would have been very difficult. Modern methods of printing and advertising make the dissemination of knowledge and information easier and quicker. Consequently the press has become a great force in our present-day civilization. Broadcasting also is fast becoming an important factor in moulding public opinion. All this is due to the scientific development in the purely physical realm. In fairness to the men of science, I must point out that they unfortunately pay little heed to the purpose to which their discoveries are put. This application is largely in the hands of politicians and others. Scientists are essentially searchers after truth, and they usually avoid extreme dogmatism. It is the politicians who give colour to their discoveries. As an example, I may quote Bertrand Russell :—

‘The dispute between anarchism and bureaucracy at present tends to take the form of one side maintaining that we want no organization, while the other maintains that we want as much as possible. A person imbued with the scientific spirit would hardly even examine these extreme positions. Some people think that we keep our rooms too hot for health, others that we keep them too cold. If this were a political question, one party would maintain that the best temperature is the absolute zero, the other that it is the melting point of iron. Those who maintained any intermediate position would be abused as timorous timeservers, concealed agents of the other side, men who ruined the enthusiasm of a sacred cause by tepid appeals to mere reason. Any man who had the courage to say that our rooms ought to be neither very hot nor very cold would be abused by both parties and probably shot in No Man’s Land. Possibly some day, politics may become more rational, but so far there is not the faintest indication in this direction’.

Scientific inventions facilitate propaganda and centralization of control, resulting in the formation of groups of human beings, which become very disciplined and very docile to their leaders, whose influence whether for good or for evil is increased. In other words, the advent of a large number of dictators in the world during the last quarter of a century may be attributed perhaps in the last resort to the progress of physics and chemistry. There is really nothing wrong in this. But the fact is that these groups are intensely national. Had there been harmony and goodwill between them, all would have been well. Each would live and work in its own way, and each would contribute to the sum total of human happiness and culture. This, however, is not so. There has been rivalry between the groups, resulting in terrible disasters. The groups might unite. I sincerely hope, they will; but will they? Take the analogy of a football match. The object of a

football team is to kick goals. If two football teams combined and kicked the ball over the two goals, in a given period of time, many more goals would naturally be scored. But who would suggest that this should be done, the object of a football team being not to kick goals but to win? Similarly the object of the different groups of human beings is not to kick goals but to win; and it is this spirit of rivalry which leads to friction.

When I look at the world to-day, I cannot help agreeing with Fisher, that in history one sees ‘one emergency following upon another as wave follows upon wave. There is only one great fact with respect to which, since it is unique, there can be no generalizations, one safe rule for the historian: that he should recognize in the development of human destinies the play of the contingent and the unforeseen. This is not a doctrine of cynicism and despair. The fact of progress is written plain and large on the page of history; but progress is not a law of nature. The ground gained by one generation may be lost by the next. The thoughts of men flow into the channels which lead to disaster and barbarism’.

Men often say that science has been a boon to mankind. But those of us who have lived through two world wars are apt to be a bit sceptical. There is one obvious fact that science in its application may or may not be an instrument for good. In fact, it is actually proving to be a potent instrument of destruction, and its unbridled use in the hands of politicians will destroy the world.

Science is used to promote the power of dominant groups rather than to make men happy; and whether it will prove to be a blessing or otherwise is still an open question.

There are two ways in which science may affect human life :—

(a) Without altering men’s passions or their general outlook, it may increase their power of gratifying their desires.

(b) It may operate through an effect upon the theological or philosophical conceptions, which are accepted in practice by most intelligent men. Of these, the latter effect is almost negligible; the first is by far the more important.

Beyond the actual facts of life and matter with which science deals, there is the question of fundamental values to be attached to human existence, which is of the greatest importance for promoting harmony on earth. Here we proceed from the realm of science into that of metaphysics and theology. But a consideration of the value of life on earth and its ultimate destiny can never be ignored, and I hope that scientific outlook will eventually offer a solution to bring about harmony between the various religious faiths. In fact, there is a tendency amongst the more advanced sections of humanity to believe that different religions are but different paths to one and the same goal. This

realization will again help to promote goodwill, and bring about peace on earth.

Science alone is not, and can never, be a panacea for all the ills with which humanity is afflicted. It is really not diabolical; but a great responsibility rests on those who wield power, for they can by their influence make either good or bad use of the science which is placed at their disposal. A change of heart in them is therefore necessary. It is also necessary that the scientists should assert themselves and allow their discoveries to be used only for good purposes. A little more of kindness is needed in this world, a little more of grace and charity. Can these qualities come from science? I wonder. Speaking as a physiologist, I wish it were possible that some substance, possibly of the nature of a hormone, could be injected into the blood of mankind, which would fill them with kindness towards their fellow men. It is only kindness and benevolence that can save mankind.

A question arises, what can be done to promote mutual goodwill amongst the nations. To bring this about, better knowledge of each other is essential. Professor A. V. Hill, who came to India in the latter part of 1943, told me that a very happy relationship exists between King's College, Cambridge (England), and Berkley College, Yale (U.S.A.). It is a purely informal arrangement, but is greatly appreciated by both parties to it. They call it an *Amicabilis Concordia*. When a member of the staff, or a student of Berkley College goes to Cambridge, he is accepted as a member of the family by King's. When a King's man goes to Yale, he is made to feel at home at Berkley. When the Provost of King's goes to New Haven, he is received with honour by the Master of Berkley College and *vice versa*.

It is possible to establish similar familiar relationships between the universities and other learned institutions in India, and corresponding bodies in Great Britain, the United States, and other countries. During my visit to the United States and Canada last year as a member of the Indian Scientific Mission, I discussed this matter with several people and the suggestion was welcomed in many places, specially in Toronto.

By establishing *Amicabilis Concordia* between the cultural institutions in different countries in this way, it will be possible to increase mutual goodwill and co-operation. It is the simplest and the best method of promoting international friendship by personal contacts.

Medicine as a science stands on a much higher pedestal than pure physical science, so far as the welfare of humanity is concerned. At a memorable address delivered at the commencement of this century in January 1901 Sir William Osler said:—

'For countless generations the prophets and kings of humanity have desired to see the things which men have seen, and to hear the things

which men have heard in the course of the wonderful 19th century. To the call of watchers on the towers of progress there had been the one sad answer—the people sit in darkness and in the shadow of death. Politically, socially, and morally the race had improved, but for the unit, for the individual, there was little hope. Cold philosophy shed a glimmer of light on his path, religion in its various guises illumined his sad heart, but neither availed to lift the curse of suffering from the son of Adam. In the fullness of time, long expected, long delayed, at last science emptied upon him from the horn of Amalthea blessings which cannot be enumerated, blessings which have made the century for ever memorable; and which have followed each other with a rapidity so bewildering that we know not what next to expect. To us in the medical profession, who deal with this unit, and measure progress by the law of the greatest happiness to the greatest number, to us whose work is with the sick and suffering, the great boon of this wonderful century, with which no other can be compared, is the fact that the leaves of the tree of science have been for the healing of the nations. Measure as we may the progress of the world materially, in the advantages of steam, electricity, and other mechanical appliances; sociologically, in the great improvement in the conditions of life; intellectually, in the diffusion of education; morally, in a possibly higher standard of ethics—there is no one measure which can compare with the decrease of physical suffering in man, woman, and child when stricken by disease or accident. This is the one fact of supreme personal import to every one of us. This is the Promethean gift of the century to man'.

These are noble words and noble sentiments; they represent typically the complacent mood of 19th century science. Since then much water has flowed under the bridge. In spite of all vicissitudes, I am glad to say, that medicine has continued to make good progress and the expectations of Osler have been fully justified. In fact, during the two world wars many important discoveries have been made in medical science for the alleviation of human suffering. We of the medical profession, who worship at the shrine of Aesculapius, have remained true to our oath of allegiance to alleviate suffering, and have not allowed our efforts to be diverted to nefarious ends.

Love of knowledge, a keen spirit of enquiry and pursuit of truth are the foundations of scientific endeavour and progress, and their essential purpose is the welfare of mankind. As an accompaniment of this scientific progress, there is need for a new moral outlook, which would show respect for all that is best in man. It is to cultivate this new moral outlook as well as to emphasize the international aspect of science, which recognizes no boundaries of race, creed or colour, that we hold to-day the inaugural celebrations of the United Nations Educational,

Scientific and Cultural Organization. I wish this world organization the best of luck, and all the success it so richly deserves.

INDEPENDENCE DAY MESSAGES

COPIES of the following messages in connection with the Independent Day celebrations on 15th August, 1947, have been received :—

1. Chinese President's telegram to Lord Mountbatten, and the reply to President Chiang.
2. Message to the Indian press from His Excellency Lord Mountbatten of Burma.
3. Message to the Indian press from Her Excellency Lady Mountbatten of Burma.
4. Message from Dr. Edward Phelan, Director-General, International Labour Office, Geneva, to Pandit Nehru, and Pandit Nehru's reply.
5. Pandit Nehru's reply to French Foreign Minister.
6. Message from High Commissioner for Canada.
7. Message from the Prime Minister and Acting Minister of Foreign Affairs, Oslo (Norway), to Pandit Nehru, and Pandit Nehru's reply.
8. Message from the Prime Minister of Australia to Pandit Nehru.
9. Message from President Chiang Kai Shek to the Prime Minister of India, and Pandit Nehru's reply.
10. Message from the Chinese Prime Minister to Pandit Nehru, and Pandit Nehru's reply.
11. 'Chant for Indian Freedom' from the Ambassador of the Republic of China.
12. Message from M. Soodarsono on behalf of the Indonesian Republic.
13. Message from H.M.'s Minister in Nepal to Pandit Nehru, and Pandit Nehru's reply.
14. Congress President's message to the nation.
15. Pandit Nehru's message to the nation.
16. Pandit Nehru's message to all Indian diplomatic representatives abroad.
17. Pandit Nehru's message to Indians overseas.
18. Moulana Abul Kasam Azad's message.
19. Dr. Rajendra Prasad's message.
20. Sardar Vallabhbhai Patel's message.
21. Flag hoisting at embassy in China.

UNITED PROVINCES MEDICAL COUNCIL

(Minutes of the meeting of the United Provinces Medical Council held in its office at Lucknow on Wednesday, 26th March, 1947, at 11 a.m.)

1. (a) THE minutes of the last meeting were confirmed but it was decided that no action be taken on resolution no. 23 till its defects were rectified.
- (b) In view of the fact that the Public Health and Medical Reorganization Committee is sitting, it was decided that the question of suggesting amendments to the United Provinces Medical Act be taken up at once, instead of being referred to a sub-committee, and the Council, after going through new proposals, suggested amendments to the said Act.
2. Government notifications notifying the elections of Khan Bahadur Dr. Mohammad Abdul Hameed and Dr. S. P. Gupta, as members of the Council, were read and recorded:

3. With reference to Medical Council resolution no. 4 of November 1946, the postponed case against Dr. Har Datt Pant, L.M.P., was considered.

Dr. Pant was not present but was represented by Mr. Ghananand Pande, Advocate, who was heard by the Council.

The Council considered the case of Dr. Har Datt Pant and decided to issue a warning to Dr. Har Datt Pant to be more careful in issuing certificates.

The Council record their extreme disapproval of the conduct of Dr. Har Datt Pant in making allegations quite uncalled for and unjustifiable against the Registrar.

In view of the fact that the representative of Dr. Har Datt Pant withdrew those remarks on behalf of his client, the Council decided that such should be expunged from the records of the Council.

4. The Council considered the case against Dr. Brij Kishore Kapur, M.B., B.S., and decided that the case against him be dropped.

5. Resolved that this Council disapproves of the specimen submitted by the New India Literature Co., Lahore, but has no objection to the publication of a directory on the lines of the English Medical Directory published by Messrs. J. and A. Churchill, Ltd., London.

6. Resolved that the question of employing unfair means by registered medical practitioners at the college or school examinations does not come under section 26 of the United Provinces Medical Act.

7. Resolved unanimously that the following resolution passed in June 1946 by the Madras Medical Council be endorsed:

'This Council resolves to request the Central Government to suitably amend the Indian Medical Council Act to make provision for an elected representative of each of the Provincial Medical Councils in India to serve on the Medical Council of India.'

8. The report of the Standing Committee, which met on 25th March, 1947, was discussed.

9. Disposed off in item no. 8.

10. Withdrawn.

11. The following resolution was passed:

'Resolved that the Director of Public Instruction be requested to appoint the registered medical practitioners, both graduates and licentiates, as examiners in Physiology and Hygiene in the Intermediate Examination of the United Provinces Education Board. Further resolved that the representative of this Council on the said Board be requested to press this demand in the meetings of the Board.'

12 to 15. Withdrawn.

16. Supplementary matters were not considered.

17. The resolution was referred to the Standing Committee.

R. N. SHUKLA,
Registrar.

N. BRIGGS,
COLONEL, I.M.S.,
President, U. P. Medical Council.

SAMIKSA

Journal of the Indian Psycho-Analytical Society

WE have received a copy of the first issue of the *Samiksa*, a new Indian Psycho-Analytical Periodical to be published quarterly. The journal is obtainable by subscription only, the annual subscription being Rs. 16 (inland) and Rs. 18 (overseas). All communications should be sent to the Indian Psycho-Analytical Society, 14, Parsibagan Lane, Calcutta 9.

THE WILLIAM GIBSON RESEARCH SCHOLARSHIP FOR MEDICAL WOMEN

MISS MAUD MARGARET GIBSON has placed in the hands of the Royal Society of Medicine a sum of money to provide a Scholarship in memory of her father, the late Mr. William Gibson of Melbourne, Australia. The Scholarship is awarded from time to time by the Society to qualified medical women who

are subjects of the British Empire; and is tenable for a period of two years, but may in special circumstances be extended to a third year. The next award will be made in October 1947.

In choosing a Scholar the Society will be guided in its choice either by research work already done by her, or by research work which she contemplates. The Scholar shall be free to travel at her own will for the purpose of the research she has undertaken.

There is no competitive examination, nor need a thesis or other work for publication or otherwise be submitted. The Society has power at any time to terminate the Grant if it has reason to be dissatisfied with the work or conduct of the Scholar.

Applications should be accompanied by a statement of professional training, degrees or diploma, and of appointments, together with a schedule of the proposed research. Applications must be accompanied by testimonials, one as to academical or professional status, and one as to general character. Envelopes containing applications, etc., should be marked on top left-hand corner 'William Gibson Research Scholarship' and should be addressed to Mr. G. R. Edwards, Secretary, Royal Society of Medicine, 1, Wimpole Street, London, W.1, and be received not later than 1st October, 1947.

The approximate value of the Scholarship will be £200 per annum.

URGENT NEED OF TACKLING THE T.B. PROBLEM OF INDIA. SERIOUS SHORTAGES OF DOCTORS, NURSES AND CLINICS. HER EXCELLENCY LADY MOUNTBATTEN'S APPEAL

'THE Tuberculosis Association of India and its affiliated bodies have been doing their best to stimulate public consciousness on tuberculosis matters in this country, but the shortage of institution facilities is acutely felt. In a vast country like India, it is estimated that there should be 4,600 clinics and, even on the basis of a minimum of one bed per death the number of beds required is 5 lakhs. To staff these, 14,200 tuberculosis doctors, 50,000 nurses and 9,200 health visitors must be formed. I understand the present authoritative figures do not approach even one per cent of these, but it is hoped that collective efforts of this Association and the Government will remove these serious shortages in the future', said Her Excellency Lady Mountbatten addressing the Eighth Annual General Meeting of the Tuberculosis Association of India at the Viceroy's House on morning of 19th July.

The following is the full text of Her Excellency's speech:—

It gives me great pleasure to welcome you here to-day. Due to unforeseen circumstances, it had been necessary to postpone the meeting till this late date and I quite realize the hardship that many of you have had to undergo in travelling long distances to join in this meeting. It is gratifying to feel from your presence here what deep interest you have in the fight against tuberculosis and how generously you respond to the call of duty to suffering humanity.

TRIBUTE TO LADY WARELL

To Lady Warell, my predecessor and the late President of this Association, we all owe a deep debt of gratitude for the keen interest she took in its aims and objects and I know you will wish me to record our grateful thanks to her for her help and guidance in furthering the activities. No words of praise can express our appreciation of the outstanding work done by our Chairman—General Hay—whose deep interest in the welfare of this Association, not only as an individual but also as a medical man, is manifest in the steady progress of the work. I thank also all the other members for their unfailing support.

I take this opportunity of conveying my grateful thanks to the Central Committee for their kindness

in electing me the President of the Tuberculosis Association of India, and though in the short time that I have been here, the pressure of work has been so overwhelming that I have as yet had the opportunity of visiting only one institution actively concerned with the Association—the Model Clinic attached to the Irwin Hospital in New Delhi—with which I was deeply interested. I look forward in the months to come to associating myself more closely with the work and visiting and supporting as many of their institutions as I can.

I might mention here that my family and I have always been particularly interested and associated with work in connection with the prevention, treatment and cure of tuberculosis and it was my own grandfather who founded and endowed what is considered to be one of the finest Tuberculosis Institutions in England, indeed I believe outstanding in the whole of Europe, i.e. The King Edward VII Midhurst T.B. Sanatorium. This Institution was founded in memory of my mother, and I myself as a member of its Governing Council.

APPALLING TOLL OF T.B. IN INDIA

As you all know, tuberculosis takes in India the appalling toll of about 5 lakhs of lives every year and disables about five times that number. The misery caused by this disease, which is not unpreventable, in thousands of families—especially those in crowded and industrial areas—can more easily be imagined than said.

More stress cannot be laid on the urgency of mustering all our resources in a relentless fight against T.B. and of educating the public on the sinister potentialities of tuberculosis and how it is preventable, the chief weapons being the Clinic, Sanatorium and Hospital staffed with qualified personnel. Equally important are the care and after-care organizations, rehabilitation centres and welfare institutes and I feel that all efforts should be made to set up State legislation to aid the various philanthropic societies in their work.

MAGNITUDE OF THE TASK AWAITING

The Tuberculosis Association of India and its affiliated bodies have been doing their best to stimulate public consciousness on tuberculosis matters in this country, but the shortage of institution facilities is acutely felt. In a vast country like India, it is estimated that there should be 4,600 clinics and, even on the basis of a minimum of one bed per death the number of beds required is 5 lakhs. To staff these, 14,200 tuberculosis doctors, 50,000 nurses and 9,200 health visitors must be found. I understand the present authoritative figures do not approach even one per cent of these, but it is to be hoped that collective efforts of this Association and the Government will remove these serious shortages in the near future.

At the same time it must be realized that without social awakening in this respect any amount of Government and Association work will be of little benefit. This has been amply justified by the advance made through the network of the 34 Provincial and State Branches in India, and I am sure that all-out efforts will be made in future years by our Association, with the co-operation of other allied societies and backed by Government, to take greater strides towards the goal.

SOME GENEROUS DONATIONS

We are deeply grateful to Haji Abdul Rahim Osman of Calcutta who at a cost of Rs. 33,000 constructed a second storey to the Women's Ward of the Lady Linlithgow Sanatorium at Kasauli and also to Mr. Khanna of the same city, whose generosity in donating Rs. 12,000 towards the construction of a Guest House in the Sanatorium premises, enabled the Association to complete the work. We are more than appreciative of the generosity of the patients, expatriates and other benefactors who have contributed over Rs. 15,000 towards our funds, in gratitude for the great service it is rendering.

In addition to the grant received from His Excellency the Viceroy's War Purposes Fund to which reference has been made in our Chairman's address, the Punjab Branch of the Indian Red Cross Society has contributed generously towards amenities of patients and helped with welfare and occupational therapy. The Association is grateful to many others, including the army authorities, who have helped us during the last year with cinema films, gramophone records, books and funds.

Your co-operation and sympathy in the activities of the Tuberculosis Association for the care and after-care of the unfortunate victims, in the education of the public and maintenance of close co-operation with other social welfare organizations will, I am sure, prove of invaluable service in the attempt to rid this great country of the dread disease.

COMMON WORK FOR NEW DOMINIONS

I am sure, however, that the thought uppermost in the minds of all of us here to-day is of the future and not of the past which bears a long record of our achievements and progress. India is on the threshold of great constitutional changes and shortly two Dominion Governments will take over from the present Government of India and our future activities will depend very largely on the programme which will inevitably be drawn up by their respective Health Departments. With future developments and increasing responsibilities of Government departments, it will, I feel, be necessary to review the entire field of work but I can assure you that whatever decision may be taken, the knowledge and experience gained by the Tuberculosis Association of India during the past eight years will be utilized to the best advantage of the peoples of both the Dominions, irrespective of political affiliations.

I thank you all for your willing co-operation in the past and feel confident that the high tradition set by this Association will be worthily maintained during the days which lie ahead.

NO VISITORS ALLOWED IN STOCKHOLM HOSPITALS

(From the *Journal of the American Medical Association*, Vol. 133, 8th March, 1947, p. 712)

THE influenza epidemic in Sweden has reached such proportions that it has been necessary to close all the Stockholm hospitals to visitors. At first only the maternity wards were forbidden territory, but with the ever increasing number of cases of influenza throughout the town it was felt imperative to extend the regulation to all hospitals for an indefinite period. A chief contributing reason to this has been the fact that many members of the hospital staffs are themselves down with influenza at a time when the full personnel is hardly able to keep up with their work. Keeping visitors away means more time for them to attend to their duties and every minute is needed. Most establishments with large numbers of workers have been badly hit by the epidemic. The Stockholm Municipal Street Car Company, for instance, had almost half of its drivers absent last week, necessitating warnings that the number of cars in service might have to be reduced. Since the cars are now dreadfully overcrowded, long suffering Stockholmers will have even worse traffic conditions to struggle with. Many companies are now experiencing the highest rates of absence due to illness in the histories of the concerns.

THE INDIAN MEDICAL SERVICE

(Abstracted from the *Lancet*, 5th July, 1947, p. 28)

SPEAKING at the annual dinner of the Indian Medical Service in London on 12th June, Lieut.-General Sir Bennett Hance, medical adviser to the Secretary of State for India, said that the forthcoming transfer of control would mean that the careers of some 500 I.M.S. officers would be prematurely ended. Three courses are,

he said, open to European officers, of which the first and third are open also to Indian officers: (1) to continue in the service of the new government or governments under existing terms, this being contingent, for European officers, on an invitation to do so; (2) if individually suitable and in certain age-service groups, to transfer to the medical service of one of the Armed Forces, or to the Colonial Medical Service; or (3) to retire on the proportionate or other pension earned under the existing rules, plus the amount of compensation laid down in the white-paper published last April.

Of the service's work for humanity history can speak: the service's work for humanity history can speak: the vector of malaria was discovered and its transmission proved by an officer of the I.M.S.; another I.M.S. officer dead-headed with the sister service in the discovery of the parasite of kala-azar, while the discovery of its vector and the final definition of its transmission is the achievement of yet another; cholera was robbed of half its terrors and three-quarters of its mortality, the treatment of amœbic dysentery was established, and the therapy of leprosy was advanced by the work of a single officer of the service; the foundations of surgery of the prostate gland and of modern plastic surgery were laid by I.M.S. officers; while their contributions to ophthalmology are common knowledge.

History provides no parallel of a service 'at once civil and military, political and penological, educational and executive, preventive and curative'. Alone of all the great administrative services, the I.M.S. was fully prepared to hand over; it bequeaths to India its two lineal descendants—the provincial civil medical services and the young but efficient Indian Army Medical Corps. It leaves, too, a highly organized independent medical profession of over 45,000 doctors, most of whom were taught by I.M.S. officers. The service can justly claim to share with Wren the proud epitaph, 'Si monumentum requiris circumspecte'.

U.P. PROVINCIAL MEDICAL CONFERENCE

A MEDICAL surgical exhibition is going to be organized in connection with the next U.P. Provincial Conference to be held at Basti, U.P., in the beginning of November 1947. All those intending to put up their products, specialities, etc., for exhibition must correspond immediately to

K. L. Srivastava, M.A., B.S.,
Basti, U.P.

The Indian Medical Gazette Fifty Years Ago

I.M.S. DINNER IN LONDON

(Reprinted from the *Indian Medical Gazette*, Vol. 32, July 1897, p. 262).

A CORRESPONDENT sends us the following interesting communication on the subject: The first annual dinner of the Indian Medical Service in England took place on 20th May at the Café Monico, London, and was in most respects a great success. The combined prevalence of plague and famine in India, by stopping the furlough of most, accounted for the comparatively small number of men on the active list that were able to avail themselves of the opportunity. Seventy-six members of the Indian Medical Service were present, and of this number no less than 45 were on the retired list.

It is gratifying to observe the great interest which these latter take in the Service and its prospects, for many attended at some inconvenience; some coming from the extreme north of Scotland, others from Ireland, etc., and coming for the occasion only, out of pure *camaraderie*; and it was a pleasure, and indeed an encouragement, to such, as are still in the Service, to observe the ruddy hue of health on the faces of almost all of the retired, many of whom were old veterans that had distinguished themselves in the mutiny; others had been well-known administrators, while some few had served all humanity, by advancing the science and practice of surgery and medicine, etc. The Service had the honour of entertaining the following guests: Lord George Hamilton, Secretary of State for India; Sir William MacCormac, President of the Royal College of Surgeons; Sir J. Diek, Director-General of the Navy; Surgeon-General Jameson, Director-General of the Medical Staff; Mr. Ritchie, Dr. Dickinson, Mr. Reginald Harrison and Mr. Sprigge. To the regret of all Lord Lister was prevented by a previous engagement from attending, while Mr. Dawson Williams, of the *British Medical Journal*, we were sorry to learn, was prevented by illness from coming.

The dinner was organized by an influential committee in London, and they had the great advantage of securing as its secretary, the services of Mr. Freyer, who, all his brother officers will be glad to know, is successfully carrying on in London the branch of surgery which he advanced and practised with such distinction in India. Sir Joseph Fayrer presided on the occasion, and discharged his duties in a manner that seemed to give satisfaction to all. As president he proposed, in separate toasts, the healths of the Queen-Empress and of the Prince of Wales and other members of the Royal Family, introducing each toast by a few remarks testifying to the good work of the Queen and various members of the Royal Family, and to the feelings of gratitude and loyalty with which they were recognized; this seemed especially appropriate this year, and to voice the feelings of all present.

The next toast of the evening was 'The Indian Medical Service' which was proposed in suitable terms by Sir William MacCormac, President of the Royal College of Surgeons, and was responded to by Sir Joseph Fayrer, who both acknowledged the recognition accorded to the Service by the eminent proposer of the toast, and was also able to supplement, from his intimate knowledge and long service, the references of the previous speaker, and as this was an inaugural dinner it was quite befitting, not only to sketch out the good and important assistance which the Service has rendered to the State in developing and consolidating the Indian Empire, but also to dwell with pardonable pride on the early beginning and traditions generally of the Service, which all tried to foster *esprit de*

corps, and to encourage and maintain the prosperity of the Service. He referred to the important part which had been played in the early days of the Company by Broughton and Hamilton; in recognition of their professional services to native potentates, the one had obtained concessions of territory for his company forming another important starting point, from which British rule rapidly extended over Bengal; while the other, by popularizing the advance of the British sway did much to smooth over difficult and delicate negotiations, which led to important results. The speaker then went on to show how much the Service had done, in times well within the memory of all, not only in advancing surgery and medicine, but in starting and developing other departments which are now important factors in the Government of India. In this connection special stress was laid on the important part which Dr. O'Shaughnessy and his experiments had played in starting the Telegraph Department in India. The speaker further enumerated the names of many who had distinguished themselves in the most various directions, but space forbids my giving further details. I will only add that Sir Joseph Fayrer expressed surprise that somebody had not written a book on the Indian Medical Service; and in these days, when books are written on such very small provocation, it is indeed a wonder that some historian has not arisen to put together the chronicles of a service whose origin and development are so intimately interwoven with that of the spread and establishment of British influence over India; the material at hand is ample for such a work, which would be interesting, not only to members of the Service, but to all that are interested in India. The next toast was the 'Sister Services', which was done justice to, and at the last moment by Surgeon-General Rice, who referred to both in appropriate terms. Sir J. Diek responded for the navy, expressing pleasure at the references made to it, and in an amusing way sketching and exemplifying various developments and advances that had occurred in the navy. Surgeon-General Jameson then responded for the medical staff, and after stating that what advanced the interests of his own branch of the Service also advanced those of the Indian Medical Service, proceeded to enumerate certain disabilities under which the medical staff laboured, explaining that some had been removed, and that others were under consideration, and adding that the War Office were most anxious to do all in their power to advance the interests of the Service. The health of the guests was next gracefully proposed by the President, Sir Joseph Fayrer, who referred to all in detail, giving special prominence to the guest of the evening, Lord George Hamilton, who, as Secretary of State for India, had, for several months past, been grappling with three most important evils that were affecting the health and prosperity of India, *viz.* (1) famine; (2) plague; (3) the injurious effects produced

on the health of the army by the increased prevalence of venereal disease. He referred to the successful way in which the first two were being confronted, and confidently anticipated that success would attend the proposed legislation for mitigating the third evil.

In replying for the guests, Lord George Hamilton spoke to the following effect: He acknowledged, on behalf of all the guests, the great pleasure it had given them to take part in so interesting an occasion as the inaugural dinner of a series of annual dinners to be held by a service which had always done such important work, and he added for himself that he had been very pleased at being able to attend. His Lordship said that everything had conspired to make the occasion a success: the dinner had been excellent, and they had listened to some most interesting speeches; for his own part increasing knowledge and experience had always rendered him somewhat sceptical about 'traditions', but he had great pleasure in acknowledging that officers of the Indian Medical Service had generally acquitted themselves with credit in the discharge of the very varied duties that had fallen to their hands—duties that were often quite outside the scope of their profession; but he specially recognized and did justice to the work that had been done by the Service in advancing science, and in its capacity as a medical service, commenting on its humanizing effects, and the assistance that it had done in developing and consolidating the Indian Empire; in illustration of which he stated that he had been informed on good authority that the dispensary on the Gilgit frontier had done signal service in reconciling the inhabitants to the new order of things, and that, in exercising generally a tranquilizing effect on the border, it was at least equal to another battalion of troops; and he further added that the statement in the last annual report that 19 millions of people had received relief from the dispensaries throughout India, was some measure of the benefits conferred on the people of India by the Indian Medical Service. He then went on to say that the president had referred to three great evils which had engrossed his attention for several months, *viz*, famine, plague and the disastrous effects of certain diseases on the health of the army. With regard to the first, he said that the Indian Medical Service had considerably contributed to the difficulties of the Government of India by so improving the sanitary condition of India that the population had increased in ten years by 50 millions, or by rather more than the population of the United Kingdom (laughter). With regard to plague, he gladly recognized the great services which had been rendered to the Government of India by the Indian Medical Service, and rendered so promptly and with such willingness on all sides; an instance of which had come to his notice the other day, in the case of an officer on leave, who had just been married, and who, on learning

that his services might be required in connection with the plague, had immediately without demur left his bride, promptly responding to the call of duty. It is difficult, he added, to overestimate the success of the medical profession, in assisting to check the spread of that plague, and in their endeavour to elucidate the mysteries that lie at its root; and in this task the doctors of other nations were also contributing: he had been amused to hear that French and German savants were renewing their struggles with great zeal, not over Alsace and Lorraine, but in Bombay, where they were wrangling over opposite views in connection with the bacillus of plague. With regard to the third point, *viz*, the effect of certain diseases on the health of the army in India, he was glad that a marked change in public opinion had enabled them to re-examine this most difficult and delicate question under more favourable circumstances, and he trusted that the evil would be mitigated by the measures that are at present under consideration. He fully recognized the great importance of the subject from every point of view, and that our very dominion in India must depend on the efficiency of our army, and he anticipated much from the judicious co-operation of all in diminishing this great evil. In conclusion, His Lordship reiterated the great interest he took in such an important service, which he felt sure would in the future continue to maintain its prosperity and traditions.

The health of the president was then proposed by Surgeon-General Cunningham, who referred to various points in his distinguished career, and after a few words of acknowledgment from Sir Joseph Fayer, the party soon broke up, all agreeing that the dinner had been a great success.

This annual gathering of the Service may be useful for other than mere convivial purposes; and it is to the interest of the Service that some organization for these annual meetings be definitely fixed on, so that their success may not be endangered by the chapter of accidents. To bring the committee more in touch with the Service, it would be expedient to appoint a Standing Committee composed of influential retired members, whose number should be added to, by selecting year by year from amongst those that are on furlough, a certain number to sit on this committee.

LONDON LETTER

(*Indian Medical Gazette*, Vol. 32, 1897, p. 268)

LONDON is going distracted over the Queen's Diamond Jubilee. The route by which the procession is to proceed is being built up on each side by a succession of scaffoldings and stagings, which are at present supremely ugly, but will, no doubt, when draped with scarlet, decorated with flags and loaded with well-dressed people, present a very splendid spectacle. The prices that are being charged for seats, windows and

rooms are enormous. St. George's Hospital, which commands a very favourable view of the procession, erected several blocks and tiers of seats, the best of which were promptly let for 20 guineas a piece. The profits of this transaction go to the support of the charity. Other hospitals and churches on the line of route have gone in for a similar means of replenishing their coffers. This is quite legitimate and consistent with the general spirit of philanthropy and charity which, at the suggestion of the august personage in whose honour the celebration takes place, underlies all commemorative schemes. But an immense amount of speculation is being carried on and extensive attempts to turn the exuberant loyalty of the nation and capital city to private profit. Syndicates and bureaux have been started which have purchased spaces and houses for erecting stands, houses have been bought for conversion into seeing places on condition of demolition and re-erection, persons who are fortunate enough to have houses or shops on the line of procession have made handsome sums by the letting of balconies and windows and roofs. There will be a rare scramble for money all round. Hotels and lodging-houses are demanding absurd rents for rooms. Carriages of every description will be let at a huge premium, and prices will for the time go up all round. It is a splendid opportunity for the labourer, the artisan and the tradesman. The railway companies are advertising excursions at ridiculously low rates to and from London, and the 22nd of June will be a very memorable day in the annals of London, and indeed in British history. The occasion will not be devoid of risk to life. There will be, according to all anticipation, a dense, eager excited crowd. Woe to the short of stature, the very young and very old, the feeble of heart and lung, the stumbler or fainter. The terrible experience of the Coronation crowd of Moscow is suggestive of very unpleasant contingencies, should Police precaution fail and the crowd for any reason get out of control. Then there is the danger of overloaded stands. The County Council has taken special thought against this risk, and no stand has been erected for which licence has not been sought and granted, and no licence has been given without satisfactory guarantee of strength and stability, and above all there is the fear of fire. So much combustible material has been accumulated, and so much carelessness is habitually exercised in checking about smouldering matches and the stumps of cigars and cigarettes. Even the illumination which will be lighted up at night along the principal thoroughfares will be a source of concern and dread. Special arrangements are being made in view of the great peril. Firemen are to be stationed at regular intervals all over the town and engines kept ready for use at all depots. The flood of Jubilee literature which is being let loose is appalling. The history of the last 60 years is being written and illustrated *usque ad nauseam*.

The medical and surgical events of the period will be chronicled in full detail in special numbers of the leading journals. The *Practitioner* has already published its Jubilee number, and the weekly journals are preparing theirs. The May number of the *Nineteenth Century* contains a very instructive retrospect of 'the progress of medicine during the Queen's reign', by Mr. Malcolm Morris, F.R.C.S. (Ed.). The items of progress which Mr. Morris chiefly dwells upon are neurology, laryngology, otology, bacteriology, anæsthesia, antiseptics, ovariectomy, the radical cure of hernia, brain, lung and abdominal surgery, litholapaxy, the reduction of puerperal and other septic fevers in hospital, the ophthalmoscope, laryngoscope, sphygmograph, clinical thermometer, Röntgen photography, and many other aids to diagnosis, specialism as a development in study and practice, and the great revolution which has taken place in the theory and practice of therapeutics from the days of blood letting calomel and saline purgatives to the days of germicides, antitoxins and animal juices and extracts. In fact a radical change has occurred during the Victorian era in pathology and praxis, and the change has been towards the better understanding of the nature and disease processes and thus more rational management. The era has also witnessed the rise and rapid advance of preventive medicine. This constitutes one of its principal glories, and there has been a great reduction of sickness and mortality resulting from more enlightened and efficient arrangements for the preservation of public health. Nor has India stood still during this period. Medicine and surgery have kept pace with European progress, and in many matters great activity, almost amounting to revolution, has been manifested. The development of medical education has been rapid and successful. The multiplication of charitable hospitals and dispensaries throughout the Empire very remarkable; and sanitation, though still backward, has been established on a firm and progressive basis. A medical profession has been created which is gradually feeling its way to organization; the mortality of the European army has been reduced from 70 to 15 per 1,000, and of the Native army from 18 to 15; and jail mortality, though still excessive, has been reduced. Vaccination has been extended and systematized, and the larger cities and towns have executed great works of water supply and drainage which have had an excellent influence on the health of their inhabitants. These and other events will no doubt be mentioned with thankfulness in reviewing the incidents of the longest and most brilliant British reign.

The first annual dinner of the Indian Medical Service was a great success. Some eighty members of the Service sat down to an excellent entertainment at the Café Monico. Sir Joseph Fayrer presided with his wonted ability and suavity. The toast of the evening was proposed

by Sir William MacCormac in happy terms, and in responding to it Sir Joseph Fayrer gave a most interesting sketch of the history of the Service and alluded in an appreciative manner to the achievements in science and literature of the many able and distinguished men who have from time risen above the level of their fellows and contributed to earn for the Indian Medical Service the great reputation which it has gained

for capacity, industry and skill. Lord George Hamilton made an excellent speech in responding for the guests. He commented on the three great anxieties of his administration—famine, the plague and the excessive prevalence of venereal disease in the European army of India. On each of these subjects he made some interesting and sensible remarks. This dinner will now become a permanent annual function.

Current Topics, Etc.

Vitamin B₁ (Thiamin) Content of Indian Foodstuffs

By M. SWAMINATHAN

(Abstracted from the *Indian Journal of Medical Research*, Vol. 34, October 1946, p. 289)

1. The vitamin B₁ content of about 150 common Indian foods has been determined by the thiochrome method.
2. Of the foods tested, dried brewer's yeast, rice polishing (from raw paddy) and wheat germ are rich sources of thiamin.
3. Among the cereals, whole cereals, e.g. whole wheat, millets, whole barley, unmilled rice and oats, are good sources containing 3 to 4 times as much thiamin as milled cereals, e.g. white flour, pearl barley and raw milled rice. Parboiled milled rice contains two to three times as much thiamin as that present in raw milled rice.
4. All dried pulses are good sources of thiamin. The common nuts and oil-seeds (with the exception of coco-nut) are also rich sources.
5. Cow's and buffalo's milk, eggs and flesh foods are fair sources; lean pork is a rich source.
6. Fresh vegetables (with the exception of green peas) and fruits are poor sources of thiamin.

The Supraspinatus Syndrome

By J. R. ARMSTRONG

(Abstracted from the *Lancet*, i, 18th January, 1947, p. 94)

CODMAN pointed out that lesions of the supraspinatus tendon and subacromial bursa were the commonest cause of pain in the shoulder.

The *mechanism* by which the syndrome is produced is simple. In the middle range of abduction of the humerus the supraspinatus tendon, with its covering bursa, impinges against the overlying acromion. When a lesion of tendon or bursa exists, this pressure causes pain, and reflex muscle spasm accompanies any movement that tends to bring the lesion into contact with the acromion.

The *cause* of most lesions appears to be trauma—usually a single contusion but occasionally repeated minor injuries. The typical history is of force applied to the abducted arm.

Symptoms and signs.—

(1) Aching of the shoulder usually referred to the insertion of the deltoid, but often of a much wider distribution. Pain may be referred to the whole of the outer side of the arm and dorsum of the forearm, or even to the neck. This widely referred aching pain is very real and, if this fact is not recognized, the surgeon may be misled or may unjustly suspect the patient of exaggerating his symptoms. Another almost constant feature is that the aching is most severe on sitting down and in bed at night, and is less troublesome while the patient is up and walking about.

(2) Painful arc of movement. This finding is one of the most distinctive features of the syndrome. The painful arc is somewhere between 60° and 120° of abduction and forward flexion; the exact site and area vary a little, as does the severity of the pain.

(3) A sharp stabbing pain on any start or sudden movement of the arm. This is referred to the region of the subacromial bursa and is probably due either to a sudden contraction of the supraspinatus or to a sudden jarring of the lesion against the acromion. This unexpected sharp pain is one of the most annoying and troublesome features of the syndrome.

Some degree of reversal of the normal scapulo-humeral movement is constant. Instead of the normal humeral movement throughout the first 90° of abduction, scapular movement takes place as soon as the painful arc is approached, and the whole shoulder is typically raised. It is often possible to localize a deep tenderness quite sharply to the area of the subacromial bursa.

There may be true limitation of movement. This greatly complicates the clinical picture and makes diagnosis difficult. The cause of a true limitation of movement is probably disuse.

Treatment.—Many different methods of treating the supraspinatus syndrome have been described. In the present series many of these measures were of doubtful value. Broadly speaking, treatment can be divided into conservative and operative. The following measures were used in the conservative treatment: Rest, active exercises, injection with local anesthetic, radiant heat and short-wave diathermy and manipulation of the shoulder.

ACROMIONECTOMY

About a third of all patients was unaffected or only partially relieved by any form of conservative treatment. In these circumstances I excised the acromion. This procedure, first suggested by Watson-Jones, removes pressure on the tendon and bursa and permits a full range of painless movement. Relieved of repeated irritation the lesion of the tendon or bursa tends to heal or resolve.

There is one important contra-indication to operation—true limitation of shoulder movement. In those cases in which disuse has led to a true limitation of movement of the shoulder-joint operation should not be undertaken before a full range of passive movement has been restored. Active exercises, if necessary a gentle manipulation followed by exercises, should be persisted with until all adhesions have been broken down.

Leprosy and Cockroaches

By C. J. WILSON

(Abstracted from the *East African Medical Journal*, Vol. XXIII, December 1946, p. 385)

THE author makes a plea for an extensive study both in the laboratory and in the field based on the recent hypothesis of Moiser regarding the rôle of cockroaches

FERTILOL—

a highly active and stable source of vitamin E and of all the other natural factors of

WHEAT GERM OIL

Each 5 minim capsule is standardized to contain

3 mg. α -TOCOPHEROL

Wheat germ oil has given better clinical results¹ in some trials and shown properties additional to those of pure α -tocopherol.

1. Vogt-Moller, P., Tier, Rund., 1942, 48.

The test of a dietary supplement

- 1 Does it contain the most important vitamins and minerals? ✓
- 2 Are the quantities related to bodily requirements? ✓
- 3 Is it in convenient dosage? ✓
- 4 Is the cost such that the physician's directions will be followed? ✓
- 5 Are additional supplements unnecessary? ✓

The diagram illustrates the extent to which Complevite tablets meet the optimal requirements of a wide variety of protective and nutritional factors.

The adult daily dose provides:—Vitamin A 4,000 i.u., vitamin B₁ 200 i.u., vitamin C 400 i.u., vitamin D 300 i.u., calcium 153 mg., iron 68 mg., trace minerals 3 p.p.m.

LOSS OF SOFT TISSUE OF CHIN AND OF MANDIBLE

Gypsona as an adjuvant in reparative surgery

CASE HISTORY. The patient was injured in July 1941, when his ship was bombed and machine gunned. Examination showed the lower lip divided and a loss of soft tissue of chin and of mandible from right molar region to left incisors. On the 29th August, 1941, two tube pedicles were raised on the neck. These were lengthened four weeks later. On the 22nd October, the scars were excised from the face and the two pedicles attached.

Fig. 2

November 11th, 1941.—The pedicles divided.

February 24th, 1942.—A bone graft was inserted.

June 26th, 1942.—An acromio-thoracic tube pedicle was raised.

July 22nd, 1942.—The pedicle lengthened.

July 31st, 1942.—The pedicle attached one end.

September 24th, 1942.—The pedicle attached the other end.

February 2nd, 1943.—A further bone graft was inserted with Gypsona P.O.P. headcap and plaster between each pair of pins.

October 20th, 1943.—Chin dimple made.

The details and illustrations are of an actual case. T. J. Smith & Nephew Ltd., of Hull, England, manufacturers of Elastoplast and Gypsona, publish this instance typical of many in which their products have been used with success.

NOT NERVOUS BUT 'NERVY'

Even in these days there is little evidence of nervousness, but overwork and strain make themselves felt however much their external manifestations be controlled.

Thus the overworked business man may suffer from headaches and insomnia, for the relief of which he needs a sedative that will increase his working capacity.

VEGANIN satisfies this need. It is composed of acetylsalicylic acid, phenacetin and codeine, each in small but sufficient dosage, and has a specific synergistic effect in disorders consequent on over-strain.

VEGANIN is neither toxic or habit-forming. It is not advertised to the public.

FEROSAN TABLETS

FERROUS SULPHATE COMPOUND

A stable and convenient preparation of ferrous sulphate, with traces of copper and manganese. One tablet of FEROSAN contains 3 gr. of ferrous sulphate, and is therapeutically equivalent to approximately 15 gr. Blaud's pill. FEROSAN TABLETS are indicated in the treatment of hypochromic anæmias, as a prophylactic during pregnancy and as a general tonic.

Bottles of 100 and 500 tablets

in the transmission of leprosy. He sets out the evidence which Moiser has produced in favour of the hypothesis as follows:—

1. Cockroaches collected from huts where lepers live often contain acid-fast bacilli resembling Hansen's bacillus.
2. Cockroaches collected elsewhere have not been found to contain similar bacilli, except very occasionally in native huts from which leprosy had not been reported.
3. Africans are frequently bitten by cockroaches.
4. Hansen's bacillus has been repeatedly recovered from the sites of cockroach bites in lepers in whom the bacillus had not previously been demonstrable.
5. Cockroaches fed on lepromatous material pass acid-fast bacilli in their faeces.
6. Cockroaches fed on such faeces themselves in turn pass similar bacilli.
7. In dried cockroach faeces these bacilli remain apparently unchanged for many months.

Tularaemic Pneumonia : Treatment with Streptomycin

By R. L. PETERSON

and

R. R. PARKER

(Abstracted from the *Public Health Reports*, Vol. 61, 23rd August, 1946, p. 1231)

A case of tularaemic pneumonia is described in which treatment with streptomycin was started immediately following diagnosis on the eleventh day of illness.

CASE REPORT

S. M. H., a 29-year-old white male employee of the Rocky Mountain Laboratory of the United States Public Health Service, became ill on the afternoon of 23rd February, 1946. The onset was sudden, beginning with a chill, followed by fever, sweating, and headache. Fever, malaise, sweating, and pain in back of the eyes persisted. Cough, together with pleuritic pain, appeared on the fourth day after onset. Sputum was scant. Physical signs were not numerous, consisting of a few scattered rales throughout the left lower lung field. The temperature ranged from 99.0°F. to 104.0°F. during this time and was spiked in character. There was no photophobia, no arthralgia, and no myalgia other than lumbar aching on the day of onset. There were no skin lesions.

On 1st March, 1946, the patient was hospitalized. Chest x-ray showed diffuse infiltration of the lower lobe of the left lung. The white blood count was 9,600, with an essentially normal differential count. There was scant watery sputum without haemoptysis. The urine contained albumin and granular casts. Fifty thousand units of penicillin were given intramuscularly, followed by 25,000 units every 3 hours.

The course remained febrile, the temperature reaching 104.2°F. or more daily. Roentgenogram of the chest on 3rd March showed more extensive and dense infiltration in the left lower lobe. On 6th March, dullness and diminished breath and voice sounds were noted posteriorly in the left lower chest. A roentgenogram on 8th March confirmed the diagnosis of atelectasis of the left lower lobe, with displacement of the heart and trachea to the left.

On 6th March, the diagnosis of tularaemic pneumonia was established by laboratory tests. Penicillin was discontinued and streptomycin hydrochloride was administered intramuscularly, 50,000 units every 3 hours for 18 doses. This exhausted the available supply.

Three days later a supply of streptomycin sulfate (Abbott Laboratories) was received through the courtesy of Chester S. Keefer, chairman of the committee on chemotherapeutics, and other agents of the

National Research Council. On 11th March, streptomycin therapy was resumed. The same dosage schedule previously employed was instituted and a total of one million units was administered.

The patient's response to streptomycin was dramatic. The drug was first administered at 4 p.m. on 6th March; the patient's temperature was 104.4°F. at 10 p.m., but by 4 o'clock the next morning it was normal and remained so except for one rise to 99.0°F. on 8th March. The pulse rate dropped from 90 and 100 to 60 and 50, and the respiratory rate likewise decreased. All subjective symptoms disappeared within 24 hours after the initial dose of streptomycin. Cough diminished, and a roentgenogram of the lung made on 13th March showed the atelectatic lobe to be reinflated. The patient was able to sit up on 12th March and was discharged from the hospital on 15th March. He had lost 29 pounds during his illness.

The patient was able to return to work on 1st April, 37 days after onset and 25 days after the initial dose of streptomycin. He gained weight rapidly. A chest film on 22nd March still showed dense diffuse infiltration of the left lower lung, although there was no cough. Another film on 26th April showed resolution to be nearly complete.

Headache

By Sir CHARLES SYMONDS

(From the *Guy's Hospital Gazette*, Vol. 60, 3rd August, 1946, p. 202)

HEADACHE is a common symptom but it is only in the last few years that we have had any clear idea of its mechanisms. There have been three main sources of information.

First there has been the opportunity during operations on the head under local anaesthesia of observing which structures are sensitive to pain. From such observations it has been shown that all the tissues covering the cranium are pain sensitive and especially the arteries. The cranium itself is insensitive, that is to say, that after the periosteum has been stripped the skull can be drilled or sawn through without the patient being aware of any sensation except the noise. Of the intracranial structures most of the dura mater, all the pialaroid and the brain substance are insensitive. The parts of the dura which are sensitive are those which cover the base of the skull, and the tentorium. Pressure upon the latter structure causes pain which is referred to the brow on the same side of the head. The falx, on the other hand, appears to be insensitive to pressure. Although the dura itself is insensitive except at the base, the larger dural arteries are everywhere sensitive; for example, crushing the middle meningeal artery causes pain. Traction upon the walls of the large venous sinuses and their main tributaries also causes pain and so does traction upon the large arteries at the base of the brain. Stimulation of the sensory nerves intracranially, the fifth, ninth, tenth and second cervical, causes pain of appropriate distribution.

It is to be noted that with the exception of the arteries and the sensory nerve trunks, all the pain sensitive intracranial structures play an important part in anchoring the brain to the cranium.

The second source of information is from the experimental production of headache. The intravenous injection of 0.1 mg. of histamine causes in most subjects a headache having the following characters. It begins one minute after the injection, reaches its maximum intensity half a minute later and gradually passes off in about ten minutes. It is of a throbbing nature and of generalized distribution. The effect of this injection of histamine upon the general circulation is as follows:—Within twenty seconds there is flushing of the face with a fall of blood-pressure. The fall of blood-pressure lasts for less than a minute, so that the headache begins when the blood-pressure is returning to normal and reaches its maximum intensity later.

It is known that histamine also causes dilatation of the arteries of the meninges and on the surface of the brain. This in turn leads to an increased volume of the intracranial contents and a rise in the cerebro-spinal fluid pressure. It is not, however, until the C.S.F. pressure has almost returned to its normal level that the headache begins. The headache, therefore, cannot be due to an increased intracranial pressure. This is further shown by the fact that histamine headache can be relieved by raising the C.S.F. pressure either by compressing the jugular veins or by the intracranial injection of normal saline. Histamine headache can also be temporarily relieved by a second injection of histamine or by the inhalation of amyl nitrite, the relief being coincident with the fall of blood-pressure caused by these drugs.

Thus it appears that histamine headache is relieved by increasing the pressure outside the walls of the intracranial arteries or by diminishing the pressure within them. This suggests that the headache is due to stretching of the arterial walls and a further clue to the sequence of events after histamine injection is provided by the observation in animals that the dilatation of the cerebral arteries continues for a short time after the arterial pressure has begun to return, so that the walls of these vessels not yet having regained their tone may be abnormally stretched by a normal internal pressure.

These observations and conclusions have been described in some detail because they have been the basis of much other work. They were made originally by picking in this country and confirmed by Wolff and others in America.

It has been shown that the headache of experimentally induced fever can, like histamine headache, be temporarily relieved by artificially raising the C.S.F. pressure; and by an ingenious method of recording the pulsations in the C.S.F. manometer, which reflects the pulsation of the intracranial and intraspinal arteries, it has been demonstrated that the onset of febrile headache is associated with an increased amplitude of pulsation, and that fluctuations in the intensity of the headache are associated with corresponding fluctuations of amplitude. It would appear, then, that the headache of fever is caused by an abnormal degree of stretching of the arterial walls, and since raising the intracranial pressure by injection of saline into the theca will relieve the headache, we may conclude that the arteries chiefly concerned are those within the skull.

Another experimental headache is that which may be produced by the withdrawal of 20 c.c. of C.S.F. by lumbar puncture. With this kind of headache we are familiar as an occasional sequel of diagnostic lumbar puncture when it is due to excessive leakage of C.S.F. This headache is remarkable for its constant relation to posture. It is relieved by the horizontal and aggravated by the erect positions. It must be due to a diminution of cerebro-spinal fluid, for the liability to headache in the erect posture can be very much reduced by making good the deficit with normal saline. It is, however, temporarily increased by jugular compressions which raises the intracranial pressure, so that it is incorrect to regard lumbar puncture headache as 'low pressure' headache. It is probably due to traction upon the pain sensitive structures anchoring the brain to the skull which are stretched in certain postures owing to the depletion of C.S.F. which normally provides a water-bed for the brain. The great venous sinuses and their tributaries and the tentorium might be especially liable to be affected in the erect posture.

Our third source of information about the mechanism of headache is observation in disease. In migraine the headache is of a throbbing character, resembling in this respect that induced by histamine or fever, and it might reasonably be expected to have the same basis, an abnormal degree of stretching of the intracranial arteries. But the headache of migraine is not relieved by raising the C.S.F. pressure. This, together with the clinical observation of increased pulsation of the temporal artery on the same side as the headache in

migraine, led to observations designed to show the relation of the amplitude of pulsation in this artery to the intensity of headache. The device for recording temporal pulsation also afforded an opportunity for observing the relation between this and the effect of ergotamine tartrate which was already known to relieve migraine headache. The result was striking. There was a constant parallelism between the amplitude of pulsation in the temporal artery and the intensity of headache on that side, and the intravenous injection of ergotamine tartrate simultaneously effected—(1) a rise of systemic blood-pressure due to general vasoconstriction; (2) a decrease of amplitude in the pulsation of the temporal artery due to local vasoconstriction; (3) diminution and eventually relief of headache.

It may be concluded that the pain of migraine is caused by dilatation and distension of cranial arterial walls and that the therapeutic effect of ergotamine tartrate depends on its ability to produce prolonged and powerful vasoconstriction.

That the headache of migraine is related to the stretching of extracranial arteries has also been shown in other ways. Pressure on the common carotid artery during an attack of migraine reduces the severity on that side and at the same time reduces in rough proportion the amplitude of pulsation in the temporal artery. When the headache is strictly unilateral, as it often is, carotid compression on the side of the headache greatly relieves it.

Ligature of the temporal artery in certain cases of migraine has given freedom from pain in this area in subsequent attacks. Thus it seems certain that stretching of the extracranial arteries is the most important source of pain in migraine, but this does not exclude stretching of the intracranial arteries as a contributory cause. In fact, there is positive evidence for this, for we know that the classical visual aura of migraine is due to disturbance of cortical function, and must therefore have an intracranial cause and, in a few cases of migraine with severe deep-seated temporal pain, ligature of the middle meningeal artery is reported to have given relief. The mechanism of migraine headache described offers an explanation of the not very uncommon occurrence in some attacks of pains in face or neck, which may be attributed to distension of the arteries in these regions.

Headache is a common but inconstant symptom of arterial hypertension, excluding consideration of the relatively rare condition known as hypertensive encephalopathy in which headache is severe and is associated with a raised C.S.F. pressure. Clinical observation shows that when headache is a prominent and frequent symptom, the patient has usually had a lifelong liability to headache under circumstances of fatigue and stress, that these are the precipitating causes of his present attacks, and that there is no relation between the attacks of headache and the height of the blood-pressure. The headaches of arterial hypertension appear to have much the same basis as those of migraine. They are not relieved by increasing the intracranial pressure, they are associated with an increased amplitude of pulsation in the extracranial arteries and they can be locally relieved by ligature of a temporal artery. Furthermore, an attack of headache can generally be relieved by an injection of ergotamine tartrate. This last observation is of especial interest, for the injection causes a rise of blood-pressure. Here is additional proof that a raised blood-pressure alone does not cause headache. The explanation offered for hypertensive headaches is that variations in the tone of the walls of the cranial arteries are common, and commoner in some persons than in others. If the blood-pressure is high, a relaxed artery will be more stretched, and so the liability to headache will be increased and the pain will be greater.

The headache of intracranial tumour was for a long time supposed to be due to stretching of the parietal dura from increased intracranial pressure, but this explanation no longer stands. Severe headache may be

present in cases of cerebral tumour when the intracranial pressure measured by a manometer is normal. Headache may sometimes be provoked by a sudden diminution of the space occupying lesion as when a cyst is tapped. Experimentally it has been shown that in a normal man the intracranial pressure can be raised by the lumbar injection of normal saline to over 500 mm. and maintained at this level for ten minutes without causing headache. An observation by Wolff and his colleagues in a man with a left frontal glioma provides a good example of the independence of headache and increased intracranial pressure. The patient had had intermittent bifrontal headache for a month, but at the moment of observation was free from headache. Lumbar puncture gave a pressure of 175 mm. Thirty-nine c.c. of fluid were withdrawn and the pressure came down to nil. Headache, chiefly left frontal, resulted and remained until the pressure was raised to its initial level by the injection of normal saline. A further elevation of pressure to 550 mm. maintained for five minutes failed to cause recurrence of headache.

We are led therefore to the conclusion that the headache of intracranial tumour is due to traction upon or displacement of pain-sensitive intracranial structures which, as we have seen, include basal dura and arteries, meningeal arteries, the venous sinuses and their tributaries and the tentorium. Such traction or displacement may be due to the local effect of the tumour or to remote effects from herniation of brain substance beneath the falx or through the incisura tentorii, or from obstruction of the cerebro-spinal fluid circulation.

This incomplete account of recent research into the mechanism of headache will, it is expected, excite curiosity. There is certainly much more to be learned about the structures and functions concerned in the production of a symptom which is one of the commonest kinds of pain.

Milk of He-goat

By C. M. DESAI

(From the *Current Science*, Vol. 15, October 1946, p. 286)

THE writer has come across an instance of a he-goat giving milk from both the teats since last November. The maximum amount secreted was 6-7 oz., but this has considerably decreased and the output to date is only 4 oz. The goat behaves quite normally in other respects and is used for stud.

Two samples of this milk were collected and analysed. The average of these two determinations were: Fat (Gerber) 4.6 per cent; total solids (gravimetric) 14.4 per cent; solids-not-fat 9.8 per cent. This milk seems to be normal compared to the average figures reported for the milk of she-goat.

Effects of Atomic Bomb Explosions at Hiroshima and Nagasaki

(From the *Journal of the American Medical Association*, Vol. 131, 15th June, 1946, p. 598)

A DISTINCTIVE feature of the atomic bomb is the large amount of radiant energy that it produces. The chief biologic effects include the results of heat, producing thermal injuries of the flash-burn type, and results of exposure to x-rays. This radiant energy was produced in an instant. Combined with and modifying and obscuring the thermal and radiation injuries are the more usual effects of the conventional types of bombs. Air-blast injury was usually of the secondary type due to flying debris or impact against fixed structures, producing fractures and ruptures of viscera. The thermal effects were striking in their intensity considering the brevity of the period during which they occurred. Clothes, wisps of hair and even an arm gave protection to the part of the body it shadowed. The intensity of the heat and the instantaneous character of

the flash are well brought out by photographs which show the profile of blades of grass in relief against the burned background of a board bunker. The instantaneous and intense radiant heat burned the wood before the grass had time to wither or wave.

The characteristic clinical course manifested by persons who suffered from radiation injury as a result of the atomic bomb explosions included weakness, anorexia, fever and often death and appeared usually within forty-eight hours. These effects would parallel experimentally induced changes in animals and represent the syndrome of radiation sickness carried to an extreme degree. The delayed effects represented injury of the irradiation sickness type. These patients presented, in addition to weakness, anorexia and weight loss, and diarrhoea.

Eight hundred cases hospitalized and about 13,000 made available for casualty survey were studied. In the cities and villages around Nagasaki and Hiroshima the victims of radiant energy were easily apparent by the characteristic flash-burns and by the frequent occurrence of epilation. There were three chief groups of symptom complexes resulting from damage to haemopoietic tissue. The first was the leukopenic group in which infection, particularly a Ludwig's type of angina, was the chief characteristic. The great bulk of leukopenic deaths occurred during the first three weeks after the bombing. The leukocytes in the circulating blood were destroyed at the same time at which the haemopoietic tissue was damaged, so that white blood cell counts as low as 200 per cubic millimetre were found in the first few days. The second was the thrombocytopenic group. From three to five weeks after the bombing a considerable number of haemorrhagic deaths occurred as a result of the thrombocytopenia caused by radiation damage to the megakaryocytes of the bone marrow. Some persons had massive haemorrhages from various body orifices. At necropsy, haemorrhages filling the pelvis of the kidney, multiple mucosal haemorrhages of the stomach and multiple diffuse haemorrhages in the meninges or even in cerebral substance were frequently seen. The third was the anemic group. Those with serious damage to the bone marrow who weathered the first few weeks showed later manifestations of anaemia with red blood cell counts in some instances dropping to a million or below. Some bone marrows, as shown by sternal biopsy, were extremely hyperplastic, while others were aplastic. The gonadal effect was much more prominent in the testis than in the ovary. Spermatogenesis was suppressed, and frequently the tubules were represented only by Sertoli cells and thickened membranes. The interstitial cells appeared to be undamaged. Injury from residual radioactivity did not result. Persons who had entered the bombed area soon after the explosion and had remained there were without deleterious effects.

The treatment given by the Japanese was inadequate, as were their hospital facilities. Blood transfusions were not used. Little more than supportive treatment was given. Repeated blood transfusions and penicillin to control infection during the leukopenic period should have materially reduced the number of deaths.

Prostatic Cancer Treated by Orchiectomy: The Five-Year Results

By C. HUGGINS

(Abstracted from the *Journal of the American Medical Association*, Vol. 131, 15th June, 1946, p. 576)

THE early evidence of clinical improvement following orchiectomy includes (among other effects) the relief of pain, improved appetite with gain in weight, decrease of anaemia and a decrease of size and sometimes the disappearance of the primary tumour and of the metastases. In one patient there has been relief of paraplegia; similar cases have been described by Nesbit and Cummings, and by Clarke and Viets.

In the laboratory, improvements of the disease after antiandrogenic therapy may be detected through changes in the acid and alkaline phosphatase activity of serum. Kearns has also demonstrated a striking decrease in the sedimentation rate of the blood after oestrogen administration.

Five patients survive the five-year period; one man has a slowly growing tumour, while in four of these cases we have been unable to detect activity of the tumour. It is true that an occasional untreated patient with prostatic cancer will live more than five years, although in such patients the tumour does not regress but remains in a slowly growing state; an explanation for prolonged survival in some untreated cases must be spontaneous androgenic deficiency through accidental physiologic failure of androgen production.

It is still impossible to predict the course of the disease following orchiectomy at this time. With respect to the four patients surviving five years after orchiectomy and with great involution of the neoplasm, the ages range from 63 to 80 years. One patient had only moderately advanced carcinomatosis, while in two men the disease was far advanced and one patient was moribund. Therefore the extent of the lesion is not of great moment. Two factors are apparently of significance in determining the effectiveness of orchiectomy: the tumour must be androgen dependent and the testis must contribute functionally significant amounts of the total production of androgen. It has been established that human prostatic cancer may be or may become independent of androgens. This evidence is based on removal of the adrenal glands in men who have had a relapse after an orchiectomy induced remission, life being supported by adrenal substitutive therapy: here the androgens were apparently abolished as determined by the excretion of 17-ketosteroids and urinary comb growth androgens, yet the cancer followed its unfavourable course. It is known that castration does not cause the epithelial cells of the normal prostate to disappear; they merely shrink and remain functionally quiescent.

The question of supplemental therapy arises in patients with unfavourable response to orchiectomy. It can be easily demonstrated that the addition of oestrogen to a small number of patients in relapse will cause improvement, as in the following case:

J. T., aged 66, had carcinoma of the prostate with associated bright pink papular metastases over the scalp, chest, abdomen and back; orchiectomy was performed and a biopsy of one of the nodules over the sternum showed a typical prostatic adenocarcinoma which was rich in acid phosphatase when stained by the method of Gomori. One year after castration many of the nodules had disappeared but other hyperæmic papules had developed in the skin over the chest.

Diethylstilbestrol 1 mg. daily was administered by mouth. Within four days the lesions had become pale and within six weeks the lesions were flat and at this time oestrogen was discontinued. Six weeks later the lesions had reappeared in their rosy elevated form and they again became flat and pale when oestrogen was given.

The beneficial effects of oestrogen have not been prolonged nor has other agent which would greatly benefit in post-orchiectomy failure been encountered.

An important consideration of the effect of relapse after orchiectomy in disseminated prostatic cancer is the disappearance of certain metastases and reappearance of lesions in other areas. This phenomenon occurred twice in the present series. It was observed most clearly in cutaneous metastasis and in bone. Orchiectomy had apparently injured cancer cells so severely in certain areas that they did not again become active.

It has previously been demonstrated that prostatic cancer sometimes grows more rapidly in metastases in bone marrow and lymph glands than in its primary location. In the present series in 4 of the 15 fatal cases the primary neoplasm became soft and remained

clinically atrophic while the disease grew in its metastatic location to cause death.

Although the effects of orchiectomy on prostatic cancer are at times very profound and prolonged, it is premature to suggest that any of these patients has been cured.

Remissions of varying length of time occurred in 18 patients among 20 with disseminated prostatic cancer treated with orchiectomy. After five years one patient is alive with slowly advancing prostatic carcinoma and in four patients there is no clinical or laboratory evidence of cancer at the present time.

The antiandrogenic therapy of cancer of the prostate demonstrates that a chemical change in the internal environment of the host has brought about a long continuing regression of a malignant neoplastic process.

A New Type of Congenital Life-long Jaundice

By F. PARKES WEBER, M.D., F.R.C.P.

(Abstracted from the *Medical Press*, 11th December, 1946, p. 440)

THE patient enjoyed good health, had hardly ever required medical aid of any kind, and continued at work. He had scars from leg ulcers, considerable deafness (old otosclerosis), and slight nystagmus. The blood bilirubin had been found in excess in the blood serum (negative direct Hijnmans van den Bergh reaction), but the urine had always been found free from bilirubin and from excess of urobilin and urobilinogen. There had never been any anaemia or enlargement of spleen or liver. No abnormal fragility of the erythrocytes had been discovered. The jaundice had not been transmitted to any one of his four children.

He died at about the age of 80 years of pneumonia developing on a stroke of left hemiplegia.

The following data, which concern his jaundice, were amongst those noted:—

Blood count: haemoglobin 110 per cent; erythrocytes 5,820,000; colour-index = 0.95; leucocytes 24,800 (polymorphonuclears 88 per cent, lymphocytes 11 per cent, large mononuclears 1 per cent). Reticulocytes: less than 1 per cent. Erythrocyte fragility test: within normal limits. Van den Bergh reaction: the direct reaction was positive; the indirect reaction was equivalent to 6.4 mg. bilirubin per cent (normal = 0.1 to 0.5 per cent). Erythrocytes: mean corpuscular diameter 6.9 μ ; mean corpuscular thickness 2.33 μ (the normal range is 1.7 to 2.5 μ). Faeces: not 'alcoholic', but well coloured. Urine: urobilin, strongly positive; bile pigment, negative; bile salts, negative.

Necropsy showed partly organized bronchio-pneumonia, old and recent cerebral softening, congenital jaundice.

The portal systems showed no evidence of fibrosis but contained an undue number of bile ducts lined with swollen epitheliums and occasionally containing bile.

The icteric symptoms were due simply to excess of blood bilirubin in his blood. Excepting for this and the history of leg ulcers, he had none of the following features ordinarily associated with familial acholuric (haemolytic) jaundice, namely, chronic splenomegaly, excess (until the end) of urobilin in the urine, excessive fragility of erythrocytes.

One cannot now ascertain whether his production of blood bilirubin had been excessive or not, nor whether there was a damming-up of blood bilirubin in the blood (high threshold for its elimination or catabolism). It seems probable, however, that there was such a damming-up of blood bilirubin as the essential cause of the life-long jaundice. If so, one would not expect to find any microscopical structural peculiarity in the organs to account for it. Thus, in cases of familial renal glycosuria there is no evidence by microscopical examination of the kidneys, pointing to the existence of a low threshold for the excretion of sugar.

Para-aminobenzoic Acid Treatment of Rocky Mountain Spotted Fever

By LEWIS B. FLINN, M.D.

JOHN W. HOWARD, M.D.

CHARLES W. TODD, Ph.D.

and

ELVYN G. SCOTT, M.T.

(Abstracted from the *Journal of the American Medical Association*, Vol. 132, No. 15, December 1946, p. 911)

THE use of *p*-aminobenzoic acid (PABA) in the treatment of several of the rickettsial diseases has been reported recently. The first report of a case of spotted fever treated with this drug was in 1945.

In the series of 10 patients treated with *p*-aminobenzoic acid, 9 under the age of 40 responded dramatically. The records of these patients are very striking when compared to those of 13 patients under the age of 40 who recovered without receiving *p*-aminobenzoic acid. The average number of days of fever in the untreated patients was 17.5 as compared to 10.5 for the patients given *p*-aminobenzoic acid. The untreated patients averaged twenty hospital days; those treated, thirteen days. In the treated patients there was a decided clinical improvement twenty-four hours before the temperature started to drop. The temperature of patients given *p*-aminobenzoic acid dropped rapidly to normal within two to four days after treatment was begun, whereas in the untreated patients the temperature gradually came down to normal over a period of about sixteen hospital days. Coincidental with the lowering of the temperature the rash rapidly faded, and the patient made a prompt clinical recovery. The average day of disease on admission to the hospital was 7.2 days for the untreated patients and 5.5 days for those given *p*-aminobenzoic acid. The average day of disease on which therapy was begun was 7.6 days or about the same day of disease as that on which the untreated patients were admitted to the hospital.

Para-aminobenzoic acid is known to be rapidly excreted by the body. In order to select the most favorable mode and schedule of therapy, studies were made of the blood levels and urinary excretion rates following administration of the drug in three different ways: (1) Three gm. orally in aqueous sodium bicarbonate, (2) three gm. as six 0.5 gm. tablets of the sodium salt and (3) three gm. intravenously as the sodium salt.

These results suggest that, due to its slower absorption, more prolonged and steadier levels of the drug in the blood may be obtained with the tablet form. The variations in blood content when administered by different routes probably result from individual differences in the subjects studied and may be related to the fluid balance.

In the few instances when it must be given parenterally—patient cannot retain the material by mouth or in the comatose patient who cannot swallow—continuous intramuscular drip, as suggested by Woodward, is probably the preferable method. As it is excreted rapidly when given intravenously a 25 per cent solution of sodium chloride is used. This solution is sterilized by filtration by a Seitz filter bringing the pH to approximately 7.0 by the addition of small amounts of crystalline *p*-aminobenzoic acid to the solution of sodium *p*-aminobenzoic acid before filtration.

The great majority of the cases reported had all the criteria for diagnosis—tick bite, fever, typical rash and a changing agglutination titre for proteus OX19. In a few cases the agglutination titre was not determined in the second week of the disease. In every such instance, however, the patient contracted the disease during the tick season in a locality known to be infected, and the rash was characteristic, occurring first on the wrists and ankles, then on the palms and soles and later spreading to the trunk.

Clinical studies suggest that the level of *p*-aminobenzoic acid in the blood is best kept in the optimum range of 30 to 60 mg. per hundred cubic centimetres by adjustment of dosage and fluid balance in each individual case.

The *p*-aminobenzoic acid was administered without complication.

Because of the rapid urinary excretion of the compound, oral administration at one or two hour intervals is required to maintain therapeutic blood levels.

Full-Term Abdominal Pregnancy

By MARY KATHLEEN LAWLOR, F.R.C.S. (Edin.)

(Abstracted from the *Proceedings of the Royal Society of Medicine*, Vol. XXXIX, No. 9, July 1946, p. 575)

FULL-TERM abdominal pregnancy, occurring in a healthy young primipara, with no history of tubal rupture or vaginal losses during pregnancy, is suggestive of a primary abdominal cystitis.

The mother, aged 26, attended the ante-natal department for the first time in November 1945 at 38 weeks' maturity with a letter from her doctor stating that the foetus was lying transversely and that he had made two unsuccessful attempts to perform a version. The pregnancy had been complicated by attacks of diarrhoea and vomiting which had always been diagnosed as enteritis.

On examination, it was not difficult to decide that the foetus lying transversely in the upper abdomen was extra-uterine. There was a rounded sub-umbilical swelling which was diagnosed as the placenta and, on vaginal examination, a normal non-pregnant uterus was found lying posteriorly to the placental mass.

Abdominal section confirmed the diagnosis. A perfectly healthy female infant weighing 7 lb. 6 oz. was extracted through a rent in the mesentery. It was lying free in the peritoneal cavity with no liquor amnii. The placenta presented as a highly vascular globular swelling attached to the anterior abdominal wall and the pelvic organs, the view of which it entirely obscured. The umbilical cord was traced to the left-hand corner of the placenta where the foetal membranes were also attached.

Every effort was made to avoid separating the placenta, the vessels of which were of an alarming size, and the abdomen was closed without drainage.

The puerperium was uneventful. The wound healed by first intention. Efforts to establish lactation were unsuccessful and there was no vaginal loss of any kind until the 5th week of the puerperium when an apparently normal period occurred, but was unusual in that it persisted for five weeks. Since then normal monthly periods have taken place, but the 4th and 5th have been a little heavier than usual.

This swelling did not show any attempt to decrease in size until the 5th month. There were no signs of calcification or inflammation. The patient began to feel stronger and healthier with the decrease in size of the placenta.

The baby (6 months old at the time of report) was thriving satisfactorily and was an exceptionally bright and attractive child.

Streptomycin Containing a Histamine-Like Factor

(Reproduced from Newsletter no. W-422, dated April 1947, prepared by the American Medical Association)

THROBBING headache, palpitation, and peripheral vasodilatation were observed uniformly in 20 young adult subjects following the intravenous administration of 50 mg. of streptomycin

containing a histamine-like factor, but a similar histamine-like reaction was observed in only 48 per cent of 23 subjects following intramuscular administration of 500 mg. of the same material. Small doses of benadryl given intravenously were effective in ameliorating these reactions to H-streptomycin. In nine fasting young adult subjects 500 mg. of streptomycin containing a histamine-like factor, administered intramuscularly, produced a significant increase in total volume of gastric secretion and the amount of free acid present.

In one asthmatic subject the intravenous administration of 50 mg. of H-streptomycin and 0.01 mg. of histamine base produced a similar degree of reduction in the vital capacity which was almost completely prevented by 30 mg. of benadryl given intravenously. In another subject essentially similar results were achieved when 0.02 mg. of histamine base was administered. Benadryl in the dosage used afforded no notable protection against the reduction in vital capacity due to acetyl- β -methylcholine chloride. These studies in man furnish further evidence that one of the contaminating substances of impure solutions of streptomycin is histamine.

(Hewitt, William L., and Curry, John J.: Pharmacodynamic Effect in Man of Streptomycin containing a Histamine-Like Factor. *J. Lab. & Clin. Med.*, **32**, 42, January 1947.)

Treatment of Multiple Sclerosis with Dicoumarin

(Reproduced from Newsletter no. W-422, dated April 1947, prepared by the American Medical Association)

THIS report is based on a study of the results of treatment of 43 patients with multiple sclerosis with dicoumarin for periods varying from six months to four years. The prothrombin time is determined before treatment is begun, twice the first week, weekly for the next month, then every two or three weeks. The dosage of dicoumarin is regulated to stabilize the prothrombin time of the undiluted plasma at about 30 seconds. If the clotting time of whole plasma rises to 40 seconds, or that of diluted plasma to more than 120 seconds, the dose should be omitted for at least four days and then begun at a lower level.

The usual initial dose is 150 mg. This is immediately cut down to 50 mg. daily until a proper prothrombin time is reached. Fifty milligrams can then be given every other day, until the prothrombin time drops below 30 seconds, when the dose is increased again. If hæmaturia occurs, administration of dicoumarin should at once be stopped and the patient put to bed. A transfusion should be given within 24 hours. In stubborn cases repeated transfusions, as many as five, have been found necessary. Administration of vitamin K, even intravenously, has not seemed to be of benefit.

Twenty-five patients suffering from a remittent form of the disease were adequately treated without interruption for a total period of approximately 61 patient years. In this group no fresh symptoms or obvious acute outbreaks occurred. Most of the 16 patients with chronic progressive disease continued in their downward course. The treatment of two patients was interrupted for one reason or another. The patients were free from new symptoms while taking treatment, but both had acute relapses when it was discontinued. In two patients large doses of dicoumarin failed to produce the expected increase in prothrombin time, and relapses occurred. The authors also reviewed the evidence that the sclerotic plaques of multiple sclerosis are a result of venular thrombosis.

(Putnam, Tracy J., et al.: Results of Treatment of Multiple Sclerosis with Dicoumarin. *Arch. Neurol. & Psychiat.*, **57**, 1, January 1947.)

Gynecomastia Due to Malnutrition

(Reproduced from Newsletter no. W-422, dated April 1947, prepared by the American Medical Association)

IN 27 cases of gynecomastia of nutritional origin, determinations of urinary 17-ketosteroids, cortins, estrogens and follicle-stimulating hormone have been made. Control studies were made on normal individuals from the military and civilian populations. In addition, cases of gynecomastia occurring in civilian life were studied. As a group, the gynecomastics showed significantly lowered values for 17-ketosteroids. Estrogens were in the low normal range. 'Cortins' were normal. No elevation of follicle-stimulating hormone was detected. The estrogen : androgen ratio was normal.

The findings distinguish this group from the gynecomastia of cirrhosis and acute hepatitis, but at the same time suggest that temporary derangement of liver function may play a prominent rôle in the pathogenesis of the lesion. A possible alternative explanation is that the pituitary-gonadic axis is primarily involved. The group was not dissimilar to certain types of gynecomastia found in the civilian population.

(Salter, William T., et al.: Gynecomastia Due to Malnutrition. II. Endocrine Studies. *Am. J. M. Sc.*, **213**, 31, January 1947.)

Chlorophyll in Wound Healing and Suppurative Disease

(Reproduced from Newsletter no. W-424, dated April 1947, prepared by the American Medical Association)

THIS paper by Bowers records his own experiences and observations as well as those of a group of over 30 officers of the surgical service of the staff of the Winter General Hospital obtained with water-soluble chlorophyll in the treatment of clean and infected

wounds. The general report covers the use of chlorophyll in over 400 clinical cases representing a variety of surgical conditions. The observations of the medical officers were compiled into the following group of opinions:

1. When using chlorophyll for infected wounds, the officers were impressed by the rapid disappearance of objectionable odours and by the remarkable cleanliness of the wound within two or three days.
2. Granulation tissue seemed to be of finer texture, more firm and to form more rapidly with chlorophyll than with other agents previously used.
3. Epithelization also appeared to be stimulated more by chlorophyll than by other agents such as penicillin.
4. No skin irritation or adverse systemic reactions have been noted and many patients have spontaneously commented that the chlorophyll wet dressing has been more comfortable than similar dressings with saline solution, boric solution or penicillin.
5. If chlorophyll is used as a wet dressing over a week or more, there is a tendency to overproduction of granulation tissue, so that after the wound is clean and odourless, it is advocated that chlorophyll ointment gauze be used instead of the wet dressing.
6. It was noted in all suppurating cases that chlorophyll caused cessation of pus formation in two or three days; and thenceforth, there was only a slight serous discharge. This includes the osteomyelitis and thoracic empyema cases which are noted for prolonged suppuration by other modes of treatment.
7. In the nose and sinus cases, the officers, some of whom used chlorophyll themselves, noted that chlorophyll gave more rapid changes in the nasal mucosa and had a quicker effect in stopping purulent drainage than other agents formerly used. All these patients have noted a freer breathing after chlorophyll instillation without the disagreeable after-effects of ephedrine.
8. All officers and patients have noted the bland qualities of chlorophyll and tolerance by the patient even when instilled into the eye, the nose, deep intra-abdominal abscess cavities and the pleural cavity.

Basic biologic data are presented from the literature and from personal research to attempt to establish a rational basis for the use of chlorophyll in clinical cases. It is to be emphasized that chlorophyll is not antibacterial and is but weakly bacteriostatic so that its beneficial effect is exerted through stimulation of the cells of the host.

The author thinks that the water-soluble chlorophyll preparations have a broad military application and that wide use is highly desirable. He does not present chlorophyll as a cure-all but is convinced that chlorophyll is the best agent now known for use in the treatment of suppurative diseases, indolent ulcers or wherever stimulation of tissue repair is desired and local application of this drug is possible.

(Bowers, W. F.: *Am. J. Surg.*, **73**, 37-49, January 1947.)

Streptomycin in Pulmonary Tuberculosis in Childhood: Results in Four Children

By HEYWORTH N. SANFORD

and

DONALD E. O'BRIEN

(Abstracted from the *Journal of the American Medical Association*, Vol. 133, 8th March, 1947, p. 691)

TREATMENT of 4 children, 7 months to 3 years of age, with pulmonary tuberculosis by the administration of 1,000,000 units of streptomycin a day for one month has resulted in defervescence in all 4, improvement in their general condition and a regression of the appearance of the pulmonary lesions in the roentgenograms. After a month of treatment with streptomycin the temperature has fallen to normal, the general condition of the child has been bettered and the roentgenograms have shown improvement of the lungs. In none of these children have the roentgenograms shown any extension of the disease into uninvolved areas of lung during streptomycin therapy, in spite of the fact that lesions were extending prior to the institution of therapy. Instead, in all these children regression of the disease has been seen during the course of treatment and has continued after treatment has been stopped.

It is well known that tuberculosis in children tends to recovery if the child is removed from its pernicious environment of exposure and if good living conditions are instituted. However, it could hardly be expected that such an improvement in the condition would occur in only a month of hospitalization. Many months of waiting for the healing to progress may thus be compressed into a much shorter period, and the danger of the occurrence of a generalized miliary form or a meningitis may be avoided.

Streptomycin: Its Clinical Uses and Limitations

By D. R. NICHOLS

and

W. E. HERRELL

(Abstracted from the *Journal of the American Medical Association*, Vol. 132, 28th September, 1946, p. 200)

THE antibiotic agent streptomycin appears to have a place in the treatment of certain important bacterial infections. With few exceptions the degree of sensitivity of organisms to streptomycin as determined by *in vitro* studies can be used as an index of the probable effectiveness of the treatment with streptomycin.

Satisfactory concentrations of streptomycin can be obtained in the blood and urine following intravenous, intramuscular and subcutaneous administration. The antibiotic is not destroyed in the gastrointestinal tract, and a large percentage of it can be recovered from the faeces when it is given by mouth. After oral administration, however, streptomycin cannot be detected in significant amounts in the blood and urine of patients. Streptomycin may be administered locally. It also may be administered by means of intrathecal injection and it may be instilled into various body cavities. Streptomycin diffuses fairly readily throughout the body. It is excreted readily in the urine without evidence of a toxic effect on the kidney. The usual daily dose of streptomycin employed in the treatment of infections is 2,000,000 to 3,000,000 units (2 to 3 gm.).

From the analysis of the results obtained in the treatment of 104 patients who received streptomycin under our own supervision and from the analysis of the results obtained in an additional group of 88 cases, certain conclusions can be made.

Streptomycin appears to be of considerable value in the treatment of bacteremia due to gram-negative organisms sensitive to its action.

Streptomycin is of definite but limited value in the treatment of infections of the urinary tract. Best

results are obtained when the organism of infection is *Proteus vulgaris* or *Aerobacter aerogenes*. Good results may be obtained at times when the organism of infection is *Escherichia coli* or *Pseudomonas aeruginosa*. Intensive treatment for a short duration appears to yield the best results.

Meningitis due to *Hæmophilus influenzae* usually responds satisfactorily to streptomycin. Additional treatment in the form of sulphonamides and anti-serum may be indicated for this infection. Streptomycin appears to be of greatest value in the treatment of tularæmia. It appears to be of definite value in the preparation of patients for pulmonary resection. Temporary or permanent eradication of sensitive organisms from the tracheobronchial tree at times can be achieved by its use. Temporary symptomatic improvement may occur from the use of streptomycin in the treatment of ozena. At this time final statements cannot be made concerning the value of streptomycin in the treatment of pulmonary and extrapulmonary tuberculosis.

Included among the infections in which streptomycin has proved of doubtful value are typhoid and paratyphoid fever, undulant fever, osteomyelitis, peritonitis and cholangitis.

Organisms at times develop resistance to streptomycin with incredible rapidity. This has a tremendously important bearing on the clinical results obtainable following its use.

No serious uncontrollable toxic reactions have been encountered from use of streptomycin in the cases herein reported. On the other hand, irreversible neurotoxic effects on the eighth cranial nerve may occur if treatment with streptomycin is prolonged.

Psychic Factors in the Development and Treatment of Obesity

By S. C. FREED

(From the *Journal of the American Medical Association*, Vol. 133, 8th February, 1947, p. 369)

STATISTICAL studies of obese persons show that overweight is responsible for the earlier development of degenerative diseases which result in increased death rate. There is little evidence that obesity is a glandular or metabolic disturbance. The psychological factors in obesity are paramount since the tendency to overeating is a strong drive for oral gratification. Any condition which increases the nervous or psychic tension of the person will cause an aggravation of this tendency. These tensions may result from environmental conditions, economic factors, monotony of food habits, organic diseases and various other causes of nervousness. In only rare cases obesity is of endocrine origin. Climacteric and premenstrual tensions are responsible for overeating due to increased nervous tensions. Similarly, puberty and pregnancy are conditions which commonly precipitate overeating through the development of anxieties and fears. To treat these cases, the psychological factor should be studied. If the nervous irritability is of a temporary nature barbiturates will be helpful. Whereas if the emotional tension is a deeper one an effort should be made to determine the cause for overeating from a psychological point of view. Amphetamine sulphate (Benzedrine sulphate) in 5 mg. doses three times daily before each food will reduce the level of satiability to a more normal one. The use of thyroid in stimulating the combustion of fat may be effective but after the dose approaches toxic levels. The administration of thyroid to an obese person will result in one of three responses:—

(1) He may lose weight (but if the food is not controlled he rapidly regains the weight).

(2) No effect is encountered although the patient may take huge amounts of the drug.

(3) There may be an increase in weight due to the development of a stronger appetite through the toxic effects of thyroid productive of nervousness and

irritability. In old persons where the cardiac reserve is small there is possibility of harms in many persons.

The ideal treatment of obesity involves education of the parents to the use of proper eating habits for their children and other psychologic training which induces a satisfactory adjustment to life through emotional maturity.

M. M. A.

Prolonged Reaction to Benadryl

By S. SCHWARTZBERG

and

D. WELLERSON

(From the *Journal of the American Medical Association*, Vol. 133, 8th February, 1947, p. 393)

REPORTED side reactions of benadryl are: drowsiness, sleepiness, nervousness, dryness of the upper respiratory passage, weakness, fatigue, ataxia, facial oedema, urinary frequency, nausea, epigastric distress, bad taste, a tendency to bleed, a sense of relaxation, tingling of the extremities or body tinnitus, chilliness, pruritis, a taste like chloroform, faintness, acute hysterical reaction, dilated pupil, stupor narcolepsy, confusion, blurred vision, sore tongue, pallor, hot flushes, aggravation of allergic state, irritability, palpitation, exhaustions, collapse, somnambulism, dizziness, numbness, cold extremities and muscular aching. To these may be added headache and acute melancholia. All these reactions disappear with the discontinuance of the drug. Allergic reactions producing asthma and other vasospastic conditions have also been reported.

Unusual and prolonged toxic manifestations in a patient after a dose of 150 mg. of benadryl are reported. Along with the usual side reactions of drowsiness, lethargy, numbness, tingling of the extremities, the patient showed symptoms of neuritis. This toxic reaction is considered to be due to the displacement of histamine in the tissues.

M. M. A.

Unusual Side Effect of Benadryl

By H. R. WEIL

(From the *Journal of the American Medical Association*, Vol. 133, 8th February, 1947, p. 393)

SYMPTOMS of nervousness, difficulty in co-ordination and muscular twitchings were experienced by a child of 3½ years on administration of benadryl, for the treatment of hay fever, rhinorrhœa, conjunctivitis and sneezing. With a dose of 150 mg. of benadryl the child showed signs of muscular twitchings of the face and involuntary spastic movements of the extremities followed by urinary incontinence. In about ten minutes he became irrational in his conversation and his speech gradually became slurred. One and a half grain of seconal produced sleep only for a short while and failed to stop the muscular twitchings. After a second nap of two hours the twitchings disappeared and the child became normal.

The child could tolerate later on 50 mg. of benadryl without any bad effect. It is suggested that the dose of benadryl should be restricted up to 2 mg. per kg. of body-weight.

M. M. A.

Unusual Reactions of Benadryl

By J. GRIEGER

S. Z. ROSENFELD

and

D. L. HARTMAN

(From the *Journal of the American Medical Association*, Vol. 133, 8th February, 1947, p. 392)

MILD toxic reactions, drowsiness, dizziness, weakness and nausea are often encountered after the administration of benadryl (B-dimethyl amino-ethyl benzhydryl

ether hydrochloride), a new drug having antiallergic and antispasmodic properties. In sixty-three per cent of patients the drug showed toxic manifestations of which drowsiness of varying degree up to narcolepsy was often noticed.

One female patient, aged 26, suffering from seborrhoeic dermatitis of unknown origin, on administration of benadryl 50 mg. three times a day to combat pruritis, complained of palpitation of heart, dimmed vision, malaise, heart burn and nausea. After a total dose of 350 mg. the patient was found unconscious in bed, cold, pale and pulseless. The drug was stopped and an injection of adrenaline chloride (1-1,000) 0.45 c.c. was given. Within half an hour the pulse was improved, and the patient was normal in three hours, with no recollection of what had happened. On re-administration of 300 mg. of benadryl again the patient suffered from similar reactions but recovered when the drug was discontinued. This shows that the drug at times produces shock-like reactions.

M. M. A.

Danger of Self-medication and Large Dosage with Benadryl

By McBORMAN

(From the *Journal of the American Medical Association*, Vol. 133, 8th February, 1947, p. 394)

A CONVENT nun, aged 18, took 2 capsules of benadryl 50 mg. each on the first day with decided relief. Encouraged by this improvement she took subsequently 40 capsules in three days. As a result she became drowsy, lethargic, confused and disoriented. Within 48 hours she however made an apparently complete recovery.

It is of interest to note that the well-being of the medicament affected the judgment of the patient as a result she increased the dosage without obtaining further advice.

M. M. A.

Benadryl, A Contributing Cause of an Accident

By B. J. SLATER

and

N. FRANCIS

(Abstracted from the *Journal of the American Medical Association*, Vol. 132, 28th September, 1946, p. 212)

WHILE it is recognized that benadryl is a very effective agent in the treatment of urticaria and in the control of pruritis in allergic dermatosis, it exhibits a common side reaction, drowsiness, in more than half of the patients taking it. This drowsiness is usually mild, but some patients report that they slept as long as eighteen hours after taking only 50 mg. of benadryl. When the dose is reduced to 10 or 20 mg., it is better tolerated and the side reactions, if they occur, are diminished. Leving, using 50 to 100 mg. of benadryl every four to six hours in his series of 400 cases, enumerated twenty-four different side reactions, with drowsiness occurring in 60 per cent of his cases.

In our series of 65 cases, drowsiness has been a common symptom twenty-five times. This figure should be increased somewhat, as many of our patients were instructed to take the drug only at bed time. Invariably they reported that they slept better than usual. Drowsiness may occur from one to three hours after taking benadryl, and this drowsiness may be cumulative if the drug is continued.

Because of this narcotic side reaction incident to the taking of benadryl, the drug may be a serious hazard when used by persons operating automobiles or in industry operating moving equipment or machinery.

Isopropyl Alcohol for Sterilization of Metal Instruments

(Abstracted from the *Journal of the American Medical Association*, Vol. 133, 8th March, 1947, p. 734)

ISOPROPYL alcohol is a somewhat stronger germicide against vegetative forms than is ethyl alcohol. In addition it has advantages of lower surface tension and greater fat solvent action. The maximum bactericidal concentration of isopropyl alcohol is full strength, as compared with a maximum bactericidal concentration of 70 per cent by weight for ethyl alcohol. The best grades of commercial isopropyl alcohol are said to be 98 to 99 per cent. The small water content of these solutions renders them less corrosive for metal instruments than the 70 per cent ethyl alcohol solution.

Unfortunately, however, neither ethyl nor isopropyl alcohol can be depended on to kill spores. Scalpels are frequently contaminated with sporulating pathogenic micro-organisms. That is probably true also of needles, scissors and other instruments which come into contact with skin. Immersion in isopropyl alcohol for several hours or even several days is not a trustworthy method of sterilizing such instruments.

Isopropyl alcohol is sold at present in unadulterated form, which is not irritating to the operator's hands or patient's skin.

Tuberculosis Statistics in the United States

(Abstracted from the *Journal of the American Medical Association*, Vol. 133, 8th March, 1947, p. 698)

SINCE the turn of the century the death rate from tuberculosis in the United States has been reduced, according to the Metropolitan Life Insurance Company's Statistical Bulletin of November 1946 (Wiping Out Tuberculosis in Our Time), from approximately 200 per hundred thousand to about 40. In the white population the disease is now a relatively minor cause of death, with a rate of 30 per hundred thousand. In 1944 forty-three states had tuberculosis death rates under 50 per hundred thousand, whereas in 1934 there were only twenty states in that category. In five states the death rate from the disease in 1944 had dropped to well below 20 per hundred thousand. The campaign against tuberculosis has been intensified greatly through the availability of increased funds and through the impetus given by the organization of the Tuberculosis Division of the U.S. Public Health Service. The Bulletin quoted expresses the opinion that tuberculosis may cease to exist in our time. Among the favourable factors may be mentioned the fact that the chances of becoming infected are now greatly diminished and that people generally live and work under more healthful conditions are better fed and have more adequate knowledge of personal hygiene. The facilities for detecting existing cases have made great advances, so that a greater proportion of unsuspected infections are being discovered in the early stages, when the chances of cure are best. The use of mass x-ray examinations in the army, in schools, in colleges, in factories and in entire communities has undoubtedly contributed much to early recognition of the disease. Tuberculosis still ranks high among the causes of death at most age periods. Among white women from 20 to 34 years of age it remains the principal cause of death, accounting for about one-fifth of all deaths in this broad age range. Among white men the disease ranks second only to accidents in the prime ages from 20 to 39 years. In these two decades of life among Negro men, according to the Bulletin, tuberculosis outranked every other cause without exception, as it did among Negro women of the age range from 10 to 39 years. The conquest of tuberculosis, if at all possible, involves not only full utilization of the existing knowledge and facilities for discovering and treating the disease but also the creation of healthful environmental conditions of work and recreation. The attack may well be concentrated in those areas and among those persons in the population where infection is most prevalent and death rates highest.

Reviews

A HANDBOOK OF CLINICAL MEDICINE: VOLUME I:—DISEASES OF THE HEART AND KIDNEY.—By J. C. Banerjee and P. K. Chatterjee. 1947. U. N. Dhar and Sons Limited, Calcutta. Pp. 184. Price, Rs. 8

THIS is the first of a series of small handy volumes intended to present clinical medicine in a manner which the authors have found useful for bedside training. The plan evidently is to first detail the various clinical methods of examination under each system and then proceed with descriptions of diseases of that system. The book opens with an introductory chapter which includes a general scheme of case taking for routine use. Then considerable space has been devoted to the investigation of diseases of the heart and kidneys which are the subject-matter of this volume. These diseases have been treated with reference to their aetiology, symptomatology, diagnosis and treatment in a concise form with an up-to-date information of them and their management. Finally, in two appendices are given the essentials of clinical electrocardiography and the methods of urine analysis. We have no doubt that the volume will prove useful to students at the bedside as well as in their examinations. An indication should have been given of the number of volumes that will complete the series.

R. N. C.

MODERN MANAGEMENT IN CLINICAL MEDICINE.—By F. K. Albrecht, M.D. 1946. Baillière, Tindall and Cox, Limited, London. Pp. ix plus 1238. Illustrated. Price, 55s.

THIS is a book mainly on diagnosis and treatment, the subjects under each system being presented in condensed, simplified and readily available form. Recognizing that there are no short-cuts in medicine, the author lays stress on a careful case-history and painstaking physical examination as the foundation stone of diagnosis, and as these are often not enough, he indicates and describes laboratory studies and specialized procedures including new advancements and techniques that are of value. The discussion of treatment is elaborate enough to give a clear picture of the rationale and technique of therapy. The diseases treated cover a wide field and include endocrinology and common skin and tropical disorders, and the last four chapters are on chemotherapy, geriatrics, the care of ambulatory patients which is full of much practical advice, and clinical laboratory medicine. In an appendix are given more routine diets and common procedures which range from lifting and turning patients to a description of the technique of blood transfusion. The book is obviously the product of much painstaking labour and judicious selection of materials and enriched by the author's own observations and experiences in the field of internal medicine. It well deserves its title and should be welcome to general practitioners, house officers and specialists who will find in it recent information about diagnosis, differential diagnosis and treatment quickly and in a succinct form. The book, as the author says, is intended for the doctor's office, not his library.

THE ACUTE INFECTIOUS FEVERS: AN INTRODUCTION FOR STUDENTS AND PRACTITIONERS.—By Alexander Joe, D.Sc., M.D. (Edin.), F.R.C.P. (Edin.), D.P.H., D.T.M. & H. 1947. J. and A. Churchill Limited, London. Pp. vii plus 276 with 64 illustrations. Price, 18s.

IN his preface Dr. Alexander Joe writes, 'There are few aspects of the diseases dealt with in which the

author has not had a good deal of personal experience and he has firmly resisted the temptation to write on subjects not covered by this'. And as he also writes in easy and fluent style, the result has been a book which is full of much practical information and pleasant to read. The diseases which he has described are nearly all more or less common: they are scarlet fever, erysipelas, puerperal sepsis, diphtheria, whooping cough, cerebro-spinal fever, enteric fever, measles, chickenpox, smallpox, mumps, rubella and erythema infectiosum. In addition there are two chapters on vaccination and serum reactions. Each disease has been described with reference to its pathology, transmission, infectivity, clinical features, diagnosis, prognosis, prophylaxis and treatment. The work will be found useful to students and practitioners who wish to brush up their knowledge of these common conditions.

R. N. C.

DIABETES.—By Lieut.-Colonel Henry J. John, M.A., M.D., F.A.C.P., M.C. 1946. The C. V. Mosby Company, St. Louis, U.S.A. Pp. 300. Illustrated

THE successful treatment of diabetes depends to a large extent on a close co-operation between the physician and his patient. To achieve this object an intelligent understanding of the underlying principles of the disease in all its various aspects is essential and we are of opinion that Colonel John's book is an useful addition to such series designedly written with that object in view.

In the present volume, the author has tried to present the problems regarding the management and treatment of diabetes to the general practitioners in a simple way. The clear and lucid style in which it is written will no doubt be appreciated by them. He has also given several simple but valuable tips regarding the effective management of diabetic patients which would be helpful to a busy practitioner.

The author has very rightly warned the practitioners about the fallacy of depending upon glycosuria as the sole criterion of sugar metabolism, though, we must admit, that we cannot share with him the same anxiety regarding the pathological consequences which are likely to follow repeated or sustained hyperglycaemia. While we are in complete agreement with him that prolonged hyperglycaemia will certainly have damaging effect on the pancreas, yet we consider statements such as 'Every day we let a patient carry hyperglycaemia he has that much less pancreas left' to be rather extreme.

J. P. B.

DEVELOPMENTAL ANATOMY: A TEXTBOOK AND LABORATORY MANUAL OF EMBRYOLOGY.—By Leslie Brainard Arey, Ph.D., Sc.D., LL.D. Fifth Edition. 1946. W. B. Saunders Company, Philadelphia and London. Pp. ix plus 616. Illustrated. Price, 35s.

IT is not usual to find practical lessons in a textbook as given in this book. They have been incorporated in the last section, are very well chosen and so illustrated as to ensure a thorough understanding of the different stages of the developmental processes.

The subject-matter of the text is grouped in two sections: one dealing with general features of embryology and the other devoted to the development of various organs and systems of the body. The practical portion forms the third part of the book and is designed for laboratory works. Although the plan and sections of the book have not altered, there has been a very large amount of rewriting and refashioning of the chapters in each section. Recent researches have necessitated a drastic revision, and by the inclusion of such new matters, the text has been brought abreast of the modern conception of the subjects. Most of the improvements are noticed in the general section.

Effective and Low Dosage Sulphonamide Therapy
with

IRGAFEN

(N,3, 4-Dimethylbenzoyl Sulphanilamide)

A well tolerated chemotherapeutic agent with definite action.
Total dosage 30-50% lower than that of other sulphonamides.

Indications :

Pneumonia, meningitis, B. coli infections, strepto- and
staphylococcal infections, dysenteric enterocolitis, etc.

Tablets — Ampoules

Anaemia

The administration of a good tonic is of first importance in the successful treatment of the various forms of anaemia. Generally accompanied by loss of appetite, this condition responds to the analeptic action of Waterbury's Compound, a preparation made from a formula containing products obtained by the enzymatic action of pancreatic ferments on cod liver oil, livers and spleens, malt extracts and hypophosphites. It is produced in a palatable form and can be administered with every confidence by the practitioner.

The text studied with practical lessons as detailed in part III would enable the reader to grasp the subject in all its essential fundamentals. The illustrations throughout the text in all the three parts are attractive and explanatory—a feature of the book that has rendered the perusal of the text both pleasant and wholesome.

We can confidently commend the book as thoroughly dependable to all students of embryology as well as to the teachers on whom fall the onerous task of guiding the students in their practical works.

The book has maintained the high standard for which Messrs. Saunders Co. are well known.

S. C. S.

A PRACTICAL HANDBOOK OF PSYCHIATRY FOR STUDENTS AND NURSES.—By Louis Minski, M.D., F.R.C.P., D.P.M. 1946. William Heinemann (Medical Books) Ltd., London. Pp. 128. Price, 6s.

This small volume contains a comprehensive collection of various aspects of psychiatry in brief. The preface states that it is written primarily for students and nurses but it is needless to say that it will prove of equal value to educators and practising members of the medical profession as psychiatry is a social and medical science.

The first chapter deals with the development of the individual which is essential to the studies in the mechanism of the normal working of the mind as well as the psychopathology of everyday life. The book gives a critical evaluation of the practical methods and therapeutic results of insulin shock therapy in schizophrenia, malaria shock therapy in general paralysis and convulsion therapy in involutional depressive states. The value of the book would be greatly enhanced if in future editions the author considers in more detail the fundamentals of psychoanalysis for psychotherapy and includes a short bibliography. The book will be a great stimulus to those interested in psychiatry.

MEDICAL RESEARCH COUNCIL. SPECIAL REPORT SERIES NO. 256. 'THE CULTIVATION OF VIRUSES AND RICKETTSIAE IN THE CHICK EMBRYO.'—By W. I. B. Beveridge and F. M. Burnet. 1946. Published by His Majesty's Stationery Office, London. Pp. 92. Illustrated. Price, 2s.

This report is the revised version of a previous Medical Research Council Monograph (No. 220) by one of its authors in which the method of growing viruses in the chorioallantoic membranes of fertile hens' eggs had been described. This technique was first used by Rous and Marphy in 1911, but as a result of pioneer studies of Goodpasture in America and Burnet in Australia, the developing egg can now be used in a number of different ways: the virus can be inoculated into the amniotic or allantoic cavities, into the yolk sac, into the veins of the membranes or even into the brain or other parts of the embryo itself. Each of these routes has its usefulness for special purposes. It has now been established that fertile hens' eggs, in spite of certain limitations, offer many advantages over other methods for the study of virus. In addition they have been found to give much greater yields of some viruses or rickettsiae than obtainable otherwise, and they are thus a very good source of material for vaccines. This has been exploited for manufacturing vaccines for typhus and yellow fever and influenza. Another use of them is a source of diagnostic reagents such as Frei's antigen for the diagnosis of lymphogranuloma venereum or the reagents needed for performing hæmagglutination test. Virus workers in these fields of study will find the present report a rich source of information. The work on which this report

is based was carried out by the authors in the Walter and Eliza Hall Institute in Melbourne.

MEDICAL RESEARCH COUNCIL. SPECIAL REPORT SERIES NO. 258. 'THE PRESERVATION OF PROTEINS BY DRYING. WITH SPECIAL REFERENCE TO THE PRODUCTION OF DRIED HUMAN SERUM AND PLASMA FOR TRANSFUSION.'—By R. I. N. Greaves. 1946. Published by His Majesty's Stationery Office, London. Pp. 64 with 20 plates. Price, 2s.

When the war broke out in 1939, it seemed certain that blood transfusion would play an important part in the treatment of casualties but difficulties were anticipated in the preservation and transport of citrated whole blood in liquid form for use in the field. Indeed, soon there was an urgent demand for satisfactory blood derivative which would be stable, readily transportable and suitable for administration to any patient. Luckily it was known at the time that therapeutic sera could be preserved by drying without injury to their protein structure and properties, and it seemed that drying, by appropriate methods, could be applied also to the preservation of human plasma or serum. This was actually done, and experimental batches of the dried material reconstituted with water, was given by transfusion to patients and shown to be safe. A blood drying unit was then established by the Medical Research Council at Cambridge under the direction of Dr. Greaves. The work of this unit which passed through severe phases is described in this report.

The new and bigger plant which was erected with a gift of £20,000 from the Wellcome Trustees produced in 1943-45 close on half a million bottles of dried plasma and serum. The method of drying by sublimation after 'high speed vertical spin-freezing' followed by secondary desiccation resulted in a very satisfactory product which was easily reconstituted and very stable even in extremes of temperature. There will be need for those life-saving products in peace-time transfusion practice, and moreover, the experience gained by the unit during the war, will be applicable in the future to the preservation of many biological products. The report is invaluable to all blood banks.

R. N. C.

MEDICAL RESEARCH COUNCIL. SPECIAL REPORT SERIES NO. 259. 'THE MURINE TYPE OF TUBERCLE BACILLUS (THE VOLE ACID-FAST BACILLUS).'—By A. Q. Wells. With notes on the morphology of infection by the vole acid-fast bacillus. By A. H. T. Robb-Smith. 1946. Published by His Majesty's Stationery Office, London. Pp. 48. Illustrated. Price, 2s.

In 1937 Dr. A. Q. Wells discovered an acid-fast bacillus giving rise to a disease in voles which he described as tuberculosis. Though it was regarded by some as a form of leprosy, further investigations showed that his description of the disease was essentially correct. The first part of the present report written by Dr. Wells himself, deals with the morphology, culture and pathogenicity of the vole bacillus and results of immunization experiments with it. The bacillus can be grown in artificial culture and is capable of producing characteristic tuberculous reactions when injected into animals; it is antigenically indistinguishable from the human and bovine types of tubercle bacillus, and it forms a tuberculin in liquid media which is very closely allied to, if not identical with, mammalian 'old tuberculin'. It is therefore fair to conclude that the organism is a third type of mammalian tubercle bacillus, and the term 'murine type of tubercle bacillus' seems to be appropriate. But of greater interest is the fact that animals injected with vole bacillus rapidly become sensitive to tuberculin, suggesting that it might confer some degree of protection against tuberculosis. Preliminary experiment carried on guinea-pigs have shown the truth of this

surmise. In the second part of the report Dr. A. H. T. Robb-Smith gives a descriptive account of the lesions in the tissues of naturally and experimentally infected animals. The report will interest tuberculosis workers. The possibility of making a field trial of the vaccinating effect of vole bacillus against tuberculosis is being considered.

Abstracts from Reports

REPORT ON THE LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE FOR 1945-46

THIS first post-war report indicates how in spite of bomb damage to the building, reduced staff and dispersal of equipments steps were taken, immediately after cessation of hostilities, to resume teaching activities of the School. Regular courses in diploma for public health, tropical medicine and hygiene, and bacteriology were begun, but such was the demand that a duplicate course in public health had to be organized. The short intensive courses in various subjects which were adapted to the needs of service medical officers and which were attended by 2,259 men and women during the war have been discontinued being no longer necessary. New enterprises are being promoted. A new department on human nutrition has been created under Professor B. S. Platt and through the generosity of the Wellcome Trust a chair of tropical medicine has been established, Brigadier Hamilton Fairley being its first occupant. A new sub-department of mycology has begun its work. The expanding field of tropical hygiene is recognized in the appointment of Dr. G. McDonald to an academic chair. The full development of occupational hygiene is under active consideration. The small new hospital for tropical diseases at Devonshire Street being unsuitable for teaching purposes, arrangements have been made to hold clinical sessions in Albert Dock, Dreadnought and Queen Mary's (Ministry of Pensions) hospitals and the Royal Army Medical College. Three senior members of the staff have retired—Professor R. T. Leiper (Parasitology), Brigadier G. S. Parkinson (Public Health) and Major P. G. Edge (Epidemiology and Statistics).

The report gives briefly some account of the work done in various departments but owing to the reasons given above it has not been possible to undertake any organized research work. Indeed the staff in some departments had to be supplemented by outside workers with expert knowledge and experience for teaching purpose. It is worth mentioning that Professor Raistrick (Biochemistry Department), as Scientific Adviser to the Ministry of Supply, contributed to the manufacture of penicillin on a commercial scale. He also visited America in connection with the production of streptomycin for clinical trials to be carried out under the Medical Research Council. The investigation into the treatment of 'carrier' cases of amœbic infection with diodoquin has been continued with encouraging results. An attempt has been made to introduce the results of many outstanding advances in entomological technique which have been made during the war into the teaching of D.P.H. and D.T.M. & H. courses. The department of medical statistics, besides

giving regular courses of instruction, is continually engaged in advising and carrying out statistical analysis of data for workers over a wide field of medical research. Attempts are being made to elucidate the life histories of mammalian and avian malarial parasites in the pre-erythrocytic stage, i.e. during the incubation period.

The Ross Institute of Tropical Hygiene which works in close co-operation with other departments of the School but retaining its individual character has taken part in the instruction of medical students as well as laymen, started some researches and done valuable work through its branches in Asia and Africa. The report also includes an account of the work of the Institute of Agricultural Parasitology at Wines Farm.

R. N. C.

ANNUAL PUBLIC HEALTH REPORT OF THE PROVINCE OF ASSAM FOR THE YEAR 1944. BY MAJOR T. D. AHMAD, B.A., M.B., Ch.B., D.P.H., D.T.M. & H., I.M.S., DIRECTOR OF PUBLIC HEALTH, ASSAM

THE birth-rate (16.77 per mille) during the year showed a further fall from that (19.06) in the previous year; and the death-rate (16.74 per mille) showed an increase over the previous year's rate (16.34). The districts of Cachar and Sylhet recorded death-rates above the quinquennial average of 16.99, while the remaining districts were below it. The highest death-rate (46.12) in rural areas was in the Baniyachang Circle in the Sylhet district, due to the continuance of the malaria epidemic which first broke out in 1942. The rate of child mortality, after showing a decline for several years, showed a sharp increase during the year; and the rise is perhaps due to the cumulative effects of disturbed conditions arising out of the war, and to the scarcity of protective foods. But the general high rates of child mortality prevailing during the past years, point to the need for a properly organized system of pre-natal care, and maternity and child welfare work, which are at present hampered for lack of funds.

Of the diseases causing death during the year, the chief are fevers, dysentery and diarrhoea, cholera and smallpox.

Fevers.—Deaths from 'fever' are mainly due to malaria and other diseases having fever as the predominant symptom. As already mentioned a large toll of life was taken by the malaria epidemic at Baniyachang. Quinine and other anti-malaria drugs continued to be supplied to the indigent malaria patients in the badly affected areas of the province. The Assam Medical Research Society, which directed its work mainly to malaria, continued its useful work. The activities of the Society suffered on account of its lending the Malaria Research Officer to the Public Health Department of the Provincial Government for employment as Malariologist in connection with the malaria epidemic at Baniyachang.

Kala-azar.—Kala-azar, which showed signs of recrudescence since 1937 and reached the peak in 1940, appeared to be on the decline during the year, though this could not be confirmed by survey works which could not be effectively maintained on account of the paucity of qualified doctors as a result of the deputation of a large number of them to military duty, and to the non-availability of suitable substitutes in their places.

Cholera.—The incidence of cholera during the year was low, the number of deaths from it being 4,107 against 15,454 of the previous year. The epidemic which broke out in 1943 continued till the early part of 1944, during which the incidence of the disease was comparatively higher.

Smallpox.—During the year smallpox was prevalent in epidemic form throughout the province; the district of Sylhet, where the disease seems to be endemic, being the worst sufferer. The number of deaths from smallpox during the year was 11,728 against 1,692 in the previous year.

Dysentery and diarrhoea.—The number of deaths from these increased slightly during the year. A total of 11,100 persons died from these diseases against 10,577 in the previous year.

Leprosy.—A total of 786 leprosy cases was treated in the Public Health Department dispensaries. As a result of the survey undertaken by the Special Leprosy Officer in an area of the Goalpara district 157 cases of leprosy was detected and a Public Health Department dispensary with an out-centre was opened for the treatment of the detected cases. As before the Missionaries and the British Empire Leprosy Association did excellent anti-leprosy work which Government again take the opportunity to appreciate. The Post-War Anti-Leprosy Scheme is under the consideration of Government.

Tuberculosis.—The Provincial Tuberculosis Association maintained steady progress in its activities. Accommodation at the Lady Reid Chest Hospital at Shillong was raised from 28 to 47. A second clinic named the Bijoyendra Clinic was also opened at Dibrugarh and it did good work.

Maternity and child welfare.—The good work done by the Red Cross Society in this sphere was continued during the year. There is still no recognized institution for the training of midwives within the province. The training centres at Sylhet and Silchar provide courses of *dhais*.

Food adulteration.—Due to the war the supply of articles of foodstuffs was generally short and adulteration was high. The administration of the Assam Pure Food Act, 1932, which lies with the local bodies still remained far from satisfactory.

Sale of quinine.—The sale of quinine and its substitutes remained under Government control under the supervision of the Director of Public Health. Considering all circumstances the province got a fair supply of quinine and other anti-malaria drugs.

Public health administration.—The year 1944 saw the fulfilment of the long-standing need of the department for its re-organization. As a consequence of the re-organization, which affected the eight plains districts of the province, the control of public health activities passed from the hands of the Civil Surgeons to the District Medical Officers of Health, who were made directly responsible to the Assistant Directors of Public Health. To cope with the increase of work that would follow the re-organization of the department a third permanent post of Assistant Director of Public Health with headquarters at Jorhat was created.

TRANSACTIONS OF THE THIRD TUBERCULOSIS WORKERS' CONFERENCE HELD IN NEW DELHI IN MARCH 1945

THIS was the first conference since 1940 and was attended by 65 delegates representing provinces and states. It lasted three days during which various administrative and clinical subjects were discussed.

In the opening speech Lieut.-General Hance, I.M.S., drew attention to the extremely inadequate provision in personnel and institutional facilities compared with the needs of the country where the annual death rate from tuberculosis is half a million and there are at least 2½ millions of active cases. He pointed out that even if all the money necessary to build all the institutions were immediately available, they could not be established because the necessary personnel to staff them is not available. He expressed the hope that soon every university will establish a T.D.D. course and that future institutions will be localized not on the tops of hills but where most needed, viz, near the houses of patients. Dr. P. V. Benjamin said that our aim should be one clinic for each 50,000 urban population and one clinic for each 100,000 rural population, some of the latter being mobile, and at least one hospital or sanatorium bed for each annual tuberculosis death; then there must be after-care agency to follow up the treated cases after their discharge. As it will take many years to achieve an object of such magnitude

he suggested that we should set about with short-term policy to fit in with the long-term programme of which an outline was given. Dr. B. Jayaram Naidu described a plan for 10-year anti-tuberculosis work in Mysore State. Dr. J. Ahmed spoke on the rising tide in tuberculosis, Dr. Riaz Ali Shah on tuberculosis during war time, and Dr. T. J. Joseph on the tuberculous soldier. In the discussion that followed, opinions were expressed that the Government should take charge of all schemes including financial provisions and that the Tuberculosis Association should lead the education campaign including education of the medical profession and publication of the scientific journals. It was also stated that at present we need more beds in hospitals and sanatoria, for without these surveys, clinics cannot be expected to serve any useful purpose.

Speaking on mass radiography Major Aspin, R.A.M.C., said that suitably practised within a well-established tuberculosis scheme, it will prove the sharpest single weapon we possess in the fight against tuberculosis but its extension to the population as a whole, in advance of adequate provision for institutional observation, treatment and after-care, would be a grave mistake. Incidentally he made a brief reference to the findings at India's first military mass radiography centre in which 3.4 per cent of pulmonary tuberculosis was discovered in 3,511 Labour Unit men and one per cent in 3,097 young Gurkha recruits. These had previously been medically examined. In reviewing tropical eosinophilia Dr. J. Frimodt-Møller gave the result of an analysis of 3,334 patients who had come to Arogyavaram Sanatorium for consultation during the years 1939 to 1944. Among them 131 or 3.93 per cent had symptoms characteristic of the syndrome with eosinophil count of 20 per cent or more. The majority (81 per cent) had a count of 50 per cent more and 7 patients above 80 per cent. Thirty-four per cent had typical x-ray findings. There was no material difference in the degree of eosinophils between patients with normal x-ray and those with typical x-ray findings, and most probably they were all suffering from the same disease. Most cases were negative to tuberculin. Analysis of the monthly figures shows that it was more common in the hot than in the cool months. Further investigation pointed towards a higher incidence in the Eastern coastal area than in the districts further inland, which seems to support Weingarten's observation that environmental factors might be of importance in its aetiology. Dr. Frimodt-Møller is inclined to think that the syndrome depends on an allergic condition in hypersensitive individuals who react to certain airborne antigens arising from grasses or other plants. This theory, he suggests, could be tried out by skin-testing eosinophilic cases and suitable controls with series of allergens prepared from the local flora. The last two papers read on the first day of the conference were on relationship of bronchial asthma and tuberculosis by Dr. P. K. Ghosh and some of the conditions that simulate pulmonary tuberculosis by Dr. R. A. Bidari.

On the second day Dr. Benjamin first spoke on the minimum standards for tuberculosis institutions. As technical adviser to the Association he had visited many clinics, hospitals and sanatoria and was struck with different standards of work; some had reached high standard of efficiency while others were inadequate. It is possible, he said, to have well-equipped wards and yet the standard of the institution may be low. On the other hand fine work has been done with patients in wards which may seem to some to be but primitive. In the subsequent discussion it was pointed out that the staff is often inadequate, that the doctor in charge of a clinic should be a whole-time man and there should be better co-ordination between hospital and sanatoria and clinics. It was also emphasized that it is vital to raise the standards of the health visitors. Dr. B. K. Sikand gave an account of his experiences of organized home treatment, a scheme introduced by the late Dr. C. Frimodt-Møller to meet the special conditions prevalent in India. The treatment was carried out for the

New Delhi Tuberculosis Clinic in two municipal wards of the city with a population between 60 and 70 thousand, all very poor people. Up to December 1944, 603 pulmonary cases came from the area, the majority being in advanced stage of the disease. Co-operation of patients depended on their education and socio-economic conditions. Seventy-five per cent of the patients left treatment within 6 months and only 16 per cent continued treatment from one to four years. The results of treatment as given in tables seem to show its usefulness, though limited, or, as Dr. Sikand puts it, the scheme succeeds only to a point. As regards preventive measures, the appalling home conditions made isolation practically impossible and it was not easy to convince the patient and his family about the infective nature of the disease. Of the contacts 13 per cent were suffering from tuberculosis of some organ or other. Dr. Sikand's conclusion is that the scheme, though good, cannot yield lasting results unless it is accompanied by improvement in housing conditions and backed by funds for social relief measures. There must also be some beds in the clinics for admission of poor patients. Drs. A. C. Ukil and P. K. Sen suggested in a paper quantitative approach to the classification of pulmonary tuberculosis (adult type) based on x-ray appearances, toxic manifestations and presence of complications. Talking on the minimum laboratory standards in tuberculosis work, Mr. R. M. Barton discussed the significance of negative sputum. The significance of the finding of occasional tubercle bacilli by sensitive methods, he said, has not yet been fully worked out. The ideal thing, he said, is to aim at a high standard of examination which must include, when the direct smear is negative, cultures of the sputum and gastric contents, or even animal inoculation. Such minimum standard is seldom attainable. With our present knowledge it is perhaps best to adhere to the standard suggested by the Association, viz, ordinary smear examination on four separate days in each of 3 months and if negative, culture methods before the sputum is declared negative. When the sputum is negative though the patient still shows clinical or x-ray evidence of disease, then if no higher standard than smears can be obtained, the discharge report must state this. Regarding the standard for the number of bacilli in a smear, Dr. Barton would prefer a suitable grouping such as 'numerous' when there are more than 10 bacilli per field, 'few' when 1 to 9 bacilli per field, and 'rare' when only a single bacillus in an occasional field. Speaking of blood examinations, he said that in making differential counts it is of the utmost importance to use one of the methods which take note of the division of the lobes of the neutrophils, viz, the Schilling count, the Arneeth count or the von Bonsdorff count. As regards estimation of the sedimentation rate, most workers are coming to the conclusion that the fine variations are not of importance, but only gross variations and a continued high or low rate is of value. In the afternoon Major S. M. K. Mallick read a paper on immunotherapy. Dr. J. Frimodt-Møller on motility of the colon after barium meal, Dr. S. K. Sen on early diagnosis and treatment of intestinal tuberculosis (said to be comparatively common in Rajputana) and Dr. B. J. Naidu on laryngeal tuberculosis.

On the third day Dr. K. Vasudeva Rao spoke on teaching of tuberculosis in medical colleges and schools. To tackle the disease, he said, it is essential to get the co-operation of general practitioners, but the position is very unsatisfactory as tuberculosis now forms an insignificant part of medical teaching. In Madras a change for the better has come in recent years; each final year student is required to attend 12 lectures, 12 clinical demonstrations and 12 bedside clinical periods in a tuberculosis hospital. But he said that is not enough and suggested (1) creation of a tuberculosis department under a separate professor, (2) three months' teaching in a tuberculosis hospital plus at least 15 lectures and (3) post-graduate courses. The remaining papers on this day were on paradoxical respiration occurring in collapse therapy by Dr. Sam

Bose, post-operative complications of thoracoplasty and their treatment by Dr. Amir-ud-din, intrapleural pneumolysis by Dr. Riaz-i-Quader, and the rôle of cardiovascular apparatus in pulmonary tuberculosis by Dr. S. N. Ahmed.

In conclusion we would suggest that a short summary be added to each paper that appears in future publications of the conference proceedings.

Correspondence

DISSOLUTION OF THE I.M.S.

THE following advance copy of a letter of retrospect and farewell, which Lieutenant-General R. Hay, C.I.E., K.H.R., I.M.S., Director-General, I.M.S., proposed to post to all officers of the I.M.S. on the eve of its dissolution, has been sent to us for publication.

Members of the Indian Medical Service :

Our service dissolves on the 14th of August, 1947, and I send you this letter of retrospect and farewell.

Our history as a service dates back to 1612 when on the formation of the East India Company into a joint-stock business, John Woodall was appointed the first Surgeon-General of the Company. He held this office for nearly thirty years and for many years was the only Surgeon-General of the Company. Until 1763, when the surgeons employed by the East India Company were combined into a regular establishment, with fixed grades for promotion, medical officers were recruited more or less on individual contracts. Though occasionally involved in the desultory fighting which took place from time to time, they were essentially civilians and engaged in purely civil duties. From 1745 onwards, however, the Company's wars in various parts of India necessitated the formation and maintenance of regular bodies of troops and in consequence the employment of military surgeons. In 1766, therefore, little more than two years after its first formal constitution, the Medical Service in India was divided into two branches, military and civil. It was combined into one service soon afterwards, but in 1796 was again split up. The separation was once more found impracticable and the two services were speedily reunited.

The professional activities of our early predecessors in the service were most varied. They were eligible for practically any post in which scientific knowledge was required. They were regularly employed, for example, in the Assay Department and in Botanical Gardens, and not infrequently went further afield. Among those extra-professionally employed, a Commission appointed in 1866, noticed a postmaster, a cotton agent, a superintendent of a school of arts, a naturalist, a political agent, a commissioner and a conservator of forests. Members of the service played an important part in the organization of both the Forest and Veterinary Departments.

A Professor of Chemistry in the Calcutta Medical College, conducted the first experiments for the introduction of the electric telegraph in India and became the first Director-General of Telegraphs in 1852. Later, a Physician-General, Madras, introduced cochineal into India and had a large share in the introduction of silk, sugarcane, coffee and American cotton.

With the increasing specialization of Government Departments and the recruitment by them of their own experts, the call on our service to fill posts outside our strictly professional sphere gradually diminished, the variety of our activities was curtailed, and we concentrated increasingly on our medical work. In 1896 the medical establishments of Bengal, Madras and Bombay were amalgamated into one service under the direct control of the Government of India and the designation 'Surgeon-General to the Government

of India' was altered to that of 'Director-General, Indian Medical Service'.

Until the first great war, the I.M.S. in spite of its basic military nature was, in fact, predominantly civil in character. The Royal Commission on the Public Services (1912-15) found that out of 748 officers 475 were engaged in civil duties. Thereafter, though from time to time the monopoly of superior civil appointments enjoyed by the service was substantially reduced, it retained its dual character, the last reorganization in 1937 fixing the military strength at 364 and the civil at 220. From 1915 the percentage of Indian recruitment steadily increased. In this regard, we can claim that we have contributed at least as much as any other branch of the Defence Services to enable this country to shoulder the responsibilities devolving on it under the new constitution. A feature of the service's history in these latter years was the creation from its ranks on the separation of Burma of a civil medical service for that country.

By 1939, many thoughtful members of the service had arrived at the conclusion that in order to meet the political and administrative requirements of modern India a fundamental reorganization of the service was overdue. A suitable reorganization would, they felt, include the creation by the Defence Services of their own medical corps. In 1943, the creation of the Indian Army Medical Corps made the abolition of the I.M.S. in its present form merely a matter of time. The far-reaching constitutional changes of 1947 have made it immediate.

As I pen these words to you, the service is being wound up and its members are dispersing. Some of us will find new careers in the service of the Crown, in the health services at home, and elsewhere in the British Commonwealth. We know that their service here has fitted them to contribute generously to their new tasks. Our Indian members will be completely absorbed, with some of their British colleagues, in the two new Dominions. To them in their new sphere and to those who will work with them, we hand on our torch. Its flame has burned brightly through nearly three centuries of distinguished and devoted service. It is our cherished hope, nay, rather, our firm conviction, that in their hands its light will not fade.

FRATER, AVE ATQUE VALE!

R. HAY,

LIEUT.-GENERAL, I.M.S.

OFFICE OF THE DIRECTOR-GENERAL,
INDIAN MEDICAL SERVICE,
New Delhi, 14th August, 1947.

STRANGE THOUGHTS

SIR,—While returning from a village after seeing a case of fibrosis of the lungs (probably specific) and walking through the meadows with the setting sun on my eyes I thought of 1835, when my father as a sub-assistant surgeon was deputed by the Government to hoist the banner of allopathy in remote, uncultured, uneducated areas of Assam villages. The stories that were told are self-instructive and one came out vividly in my mind. Probably it is known that like present-day hawkers sub-assistant surgeons were sent from village market to village market with panniers to let people know that western civilization has brought in a new system of treatment. They were armed with a gramophone to attract people. The existing systems of medicines vehemently opposed this system of medicine and anti-propaganda against the mixing of visible quantity of water came as a death blow to the doctors. The result of this anti-propaganda stood as a stumbling block and my poor father was being heckled by his superiors for not having any patient in well-populated villages. Luckily a thought came unto his head. He took pure nitric acid and a pice in the next market; placed his table and started showing the effect of the acid on the copper. The coppery fume frightened the people and he asked a volunteer if he would dare to have a pure drug like this fiery thing without water.

That had a dramatic effect and the banner of allopathy was hoisted in that village. I, his son, practising near that village, thought of that story. Then I thought of the case that I have just seen. Poor girl has been riddled with all sorts of injection like a bull's eye in a target practice, but nobody has given her a dose of Gees linctus or a grain of pot. iodide. Bhoze Committee says there are too few doctors in India. They never looked into the amount of syringes and doctors' almirahs that are lying astray in the villages. Every Tom, Dick and Harry, who had either been a cook or a household servant of a doctor, is an ambitious doctor. To-day while recognition to some private school doctors are being given the backbone of the medical practice is being kept away from the council. The council and the Harley Street practitioners have probably never thought of these L.M.P.s and L.M.F.s and Tom, Dick and Harry. I thought of my father with his banner and the world war II.

The sun has now set and the dusk was fast approaching, I thought of the sun that has set and the moon that will come. All of a sudden I thought of the 'Committee to consider the claims of the indigenous systems of medicine' and again I thought of nitric acid and copper and of Tom with his aqua distillata injection ampoule with a four anna visits; of Dick and his M&B 693 tablets three a day and eight annas a day practice and of Harry injecting scores of cases as syphilis (dhobies itch). Iron arsenic in anæmia of all description. A target practice in a case of fibrosis of lungs has brought in a questionable reputation to a reputed system of medicine.

Atebrin came as a boon for poor India, but it was thrown out because one in a thousand it may cause insanity, or was it because Tom's syringe will rust? Paludrine is coming, but will it thrive in the rustic soil? Vive la penicillin, but it must be available for Dick's worm-eaten almirah. Ampoules of all descriptions are welcome. Who cares as long as Messrs. So and So can sell all his panacea and Harley Street gets its patients.

I am the only registrable practitioner in about a five square miles area, but my duty has come to giving benediction and hearing the sad tales of how many injections were given and how the lands and herd were sold first to Tom then to Harry and then to Dick. A stethoscope in this area is a radio-active dictaphone which is alive and not only tells the public that a doctor is moving about but also tells the doctor that bronchitis is severe pneumonia and will require glucose injection and a case of heart failure will require glucose.

X.

TETRACHLORETHYLENE POISONING AND TREATMENT

To the Editor, INDIAN MEDICAL GAZETTE

SIR,—Reading in the March 1947 issue of *I.M.G.*, a case with toxæmia due to tetrachlorethylene was brought back to my memory.

In August 1946, I sent an I.O.R. to a local civil hospital to be treated for fever. Malaria was suspected and his temperature touched normal after quinine treatment. The M.O. of the hospital finding the patient to be very anæmic thought the cause to be ankylostomiasis. Unfortunately a microscopic examination of stools was not done, as there were no facilities for it.

He was given three capsules of 15 min. tetrachlorethylene (Allen and Hanbury's) each at hourly intervals on an empty stomach at 7, 8 and 9 a.m. At 10 a.m. he was given the mist. saline 2 oz. At 10-30 a.m. he vomited the saline and was drowsy; about half an hour later he was semi-conscious, just being roused for a minute or two. He vomited once again and then followed the spasms of muscles. The vomitus contained clear watery fluid with a bit of mucus, etc. The spasms were very similar to those of strychnine poisoning. The fits used to come on at intervals of 8 to 10 minutes. In the beginning it was just stiffening of arms and legs, with twitching of facial

muscles. Later, the convulsions were more severe and he was getting opisthotonos. He was unconscious in between the fits. I was informed of his condition as soon as he got his first fit. The available history did not suggest any other cause excepting poisoning by tetrachlorethylene.

Looking up Martindale's Extra Pharmacopoeia (only book available for reference) as to poisoning symptoms and antidote for tetrachlorethylene did not help much. The book said that carbon tetrachloride caused poisoning and that the spasms and convulsions were relieved by calcium chloride intravenously—working on the assumption the tetrachlorethylene is more or less a similar preparation. Calcium gluconate 10 per cent 10 c.c. intravenously was given at 11-30 a.m. Strange to say the patient did not get any repetition of the fits after that. Another injection was given at 3-30 p.m. the same day. He was unable to talk for 3 days. Although he could hear and would ask for food and drinks by signs on the very second day, he recovered fully. Later, he informed that he had no recollection of his experience after the first vomit.

OM PRAKASH, M.B., B.S.

239/241, MOGHUL STREET,
RANGOON.

Any Questions

STORAGE AND USE OF PENICILLIN

1. How long penicillin in dry state retains its potency in ordinary room temperature after it is taken out of cold storage? Does postal transmission which usually takes 3 to 4 days to reach the subdepot from the main depot seriously affects its usefulness?

2. Does its potency gradually diminish, and if so, can it be compensated to some extent by increase in dosage? Is there any difference as regards its loss of potency when it is stored in dry state or in normal saline solution?

3. In outlying countryside, where a refrigerator is not available, is there any justification in its use when the drug has to be kept in ordinary room temperature for a period of 3, 5 or even 7 days?

4. To maintain adequate concentration in blood, injections at three hours' interval are recommended. In outlying places, particularly in private practice in rural areas, such frequent injections are often difficult to continue owing to absence of a doctor in constant attendance. In such instances two or three injections per day may at most be arranged. In such a case, can a modified penicillin *cum* sulfa drug treatment be reckoned superior to sulfa drug treatment alone and is worth giving a trial?

J. C. BHATTACHARJEE, L.M.P.,
Assistant Medical Officer, D. H. Railway.

THAKURGANJ,
PURNEA.

[No. 1. No definite data available. Highly purified crystalline penicillin is reported to retain its full potency at ordinary temperature for quite a long time. Postal transmission which takes 3 to 4 days would therefore not affect the potency of this material.

Commercial penicillin received during the latter part of 1946 are known to be about 80 per cent pure. There is every possibility that this material would retain its potency during postal transmission.

No. 2. Yes, by increasing the dosage to a certain extent this can be compensated. However, both these factors are naturally indefinite and one will have to depend largely on judgment. Penicillin is much more stable in the dry stage than in solutions.

No. 3. Already answered in no. 1. In case of solutions of penicillin however this should be used up within 24 hours.

B. M.

No. 4. It has been considered that two or three peaks of concentration in the blood, reached with a high dose, are as good as a constant medium level.

EDITOR, I.M.G.]

Service Notes

APPOINTMENTS AND TRANSFERS

LIEUTENANT-COLONEL M. L. AHUJA, Director, Pasteur Institute, Coonoor, is appointed to officiate as Director, Central Research Institute, Kasauli, with effect from the 8th May, 1947, *vice* Lieutenant-Colonel H. W. Mulligan, granted leave.

Major T. Sommerville, Assistant Director, Central Research Institute, Kasauli, is appointed to officiate as Director from the 14th April to the 7th May, 1947, *vice* Lieutenant-Colonel H. W. Mulligan.

The Secretary of State for India has sanctioned the reversion to military employment of Major H. D. R. Zscherpel of the North-West Frontier Province I.M.S. Cadre, with effect from the 19th April, 1947.

Major R. R. Rao is appointed Medical Adviser (Pensions) (D.A.D.M.S.), in the Defence Department (Pensions Branch), 8th May, 1947.

Major M. Jafar, Director, Public Health, Bengal, is appointed Public Health Commissioner with the Government of India, with effect from the 23rd May, 1947.

(AIR BRANCH)

The officers mentioned below of the I.M.S. (E.C.) are granted Emergency Commissions:—

ROYAL INDIAN AIR FORCE—MEDICAL BRANCH

To be war substantive Flight-Lieutenant

Habibullah Khan Khalil. Dated 7th January, 1947.

Prem Raj Govind. Dated 7th January, 1947.

Puthsala Dharma Raj. Dated 8th January, 1947.

Alla-ud-Din. Dated 27th January, 1947.

Ziauddin Khan. Dated 3rd February, 1947.

Syed Baqir Hussain Gardezi. Dated 7th February, 1947.

Mohammad Aslam Khan. Dated 8th February, 1947.

Ramamurti Arunachalam. Dated 8th February, 1947.

George Antony Paulie. Dated 2nd March, 1947.

Raghibir Singh Rao. Dated 3rd March, 1947.

Dina Nath Maniktola. Dated 4th March, 1947.

Pushpala Venkatrao. Dated 6th March, 1947.

Rama Krishna. Dated 13th March, 1947.

LEAVE

Lieutenant-Colonel Jaswant Singh, O.B.E., Deputy Director, Malaria Institute of India, Delhi, is granted war concession leave for 4 months, for rest and recreation, with effect from the 12th May, 1947.

Captain T. P. Binns, Medical Officer, and His Britannic Majesty's Acting Vice-Consul, Kashgar, is granted leave on average pay for 4 months and 17 days (including additional leave for 1 month and 4 days) combined with leave on half-average pay for 8 months and 17 days, with effect from the 19th October, 1946. On the expiry of this leave his services will be replaced at the disposal of the Director of Medical Services in India.

PROMOTION

Major-General R. Hay, C.I.E., is granted the local rank of Lieutenant-General without effect on pay and pension whilst holding the appointment of Director-General, I.M.S. Dated 12th March, 1946.

RETIREMENTS

Major J. G. Durning. Dated 28th August, 1946.
 Major R. DeSoldenhoff. Dated 5th October, 1946.
 Major S. C. Colbeck. Dated 26th October, 1946.
 Captain G. A. Graham retires, receiving a gratuity.
 Dated 20th September, 1946.

RELINQUISHMENTS

The undermentioned officer is permitted to relinquish his commission :—

INDIAN LAND FORCES—INDIAN MEDICAL SERVICE
 SECONDED TO THE INDIAN ARMY MEDICAL CORPS

(Emergency Commission)

Ty. Lieutenant-Colonel F. M. Graham. Dated 15th July, 1946.

The undermentioned officers are permitted to relinquish their commissions on release from army service and are granted the honorary rank of Lieutenant-Colonel :—

INDIAN LAND FORCES—INDIAN MEDICAL SERVICE
 SECONDED TO THE INDIAN ARMY MEDICAL CORPS

(Emergency Commissions)

Ty. Lieutenant-Colonel Dwarkalal Narainlal Rai. Dated 3rd August, 1946.

Major Girdhari Lal Puri. Dated 18th December, 1946.

The undermentioned officer is permitted to relinquish his commission on release from army service and is granted the honorary rank of Major. His services are replaced at the disposal of the Government of N.W.F.P. with effect from the date specified :—

INDIAN LAND FORCES—INDIAN MEDICAL SERVICE
 SECONDED TO THE INDIAN ARMY MEDICAL CORPS

(Emergency Commission)

Captain K. A. Jabbar. Dated 22nd April, 1946.

The undermentioned officer is permitted to relinquish his commission on release from army service and is granted the honorary rank of Major. His services are replaced at the disposal of the Government of Mysore with effect from the date specified :—

INDIAN LAND FORCES—INDIAN MEDICAL SERVICE
 SECONDED TO THE INDIAN ARMY MEDICAL CORPS

(Emergency Commission)

Ty. Major Navaratna Srinivasa Rao. Dated 4th June, 1946.

The undermentioned officers are permitted to relinquish their commissions on release from army service and are granted the honorary rank of Major :—

INDIAN LAND FORCES—INDIAN MEDICAL SERVICE
 SECONDED TO THE INDIAN ARMY MEDICAL CORPS

(Emergency Commissions)

Ty. Major M. M. A. Dubash. Dated 18th June, 1946.
 Major S. N. Seal. Dated 26th August, 1946.
 Ty. Major P. B. Koppiker. Dated 24th September, 1946.

Major K. K. Seal. Dated 14th November, 1946.
 Ty. Major K. S. Iyer. Dated 27th November, 1946.
 Major V. G. Pande. Dated 23rd December, 1946.
 Major S. B. Sinha. Dated 17th January, 1947.
 Major N. S. Sankaranarayanan. Dated 2nd February, 1947.

Ty. Major R. V. Padmanavan. Dated 10th February, 1947.

Major J. C. Sen. Dated 23rd February, 1947.

Major B. Singh. Dated 31st March, 1947.

Major G. S. Sidhu. Dated 10th April, 1947.

Major M. Aslam. Dated 29th April, 1947.

The undermentioned officers are permitted to relinquish their commissions on release from army service and are granted the honorary rank of Major :—

INDIAN LAND FORCES—INDIAN MEDICAL SERVICE
 SECONDED TO THE INDIAN ARMY MEDICAL CORPS

(Emergency Commissions)

Major C. B. Chaudhury. Dated 29th August, 1946.
 Ty. Major K. N. Chakraborti. Dated 8th November, 1946.

Ty. Major P. C. Banerjee. Dated 21st November, 1946.

Major P. N. Roy. Dated 21st November, 1946.

Ty. Major G. J. Bhatt. Dated 26th November, 1946.

Major M. N. Rajan. Dated 27th November, 1946.

Captain S. C. Sarkhel. Dated 22nd December, 1946.

Ty. Major C. M. Nair. Dated 1st January, 1947.

Ty. Major K. N. H. Rizvi. Dated 22nd January, 1947.

Ty. Major U. M. Rao. Dated 5th February, 1947.

Ty. Major S. C. Bagchi. Dated 25th February, 1947.

Ty. Major H. A. Davidson. Dated 5th March, 1947.

Captain M. Ahmed. Dated 9th March, 1947.

Ty. Major N. G. Rajulu. Dated 26th March, 1947.

(WOMEN'S BRANCH)

Ty. Major (Miss) A. M. Pichaimuthu. Dated 21st October, 1946.

The undermentioned officers are permitted to relinquish their commissions on release from army service and are granted the honorary rank of Captain :—

INDIAN LAND FORCES—INDIAN MEDICAL SERVICE
 SECONDED TO THE INDIAN ARMY MEDICAL CORPS

(Emergency Commissions)

Captain M. L. Datta. Dated 10th March, 1946.

Captain F. Khan. Dated 13th June, 1946.

Captain C. N. N. Nambison. Dated 3rd September, 1946.

Captain S. R. Rao. Dated 10th September, 1946.

Captain P. Chandra. Dated 10th October, 1946.

Captain M. K. Siddiqui. Dated 5th November, 1946.

Captain M. V. Singh. Dated 24th November, 1946.

Captain D. C. Banerjee. Dated 1st December, 1946.

Captain G. Venkataramaniah. Dated 4th December, 1946.

Captain G. Das. Dated 17th December, 1946.

Captain G. C. Aubunathan. Dated 2nd January, 1947.

Captain S. K. Bose. Dated 10th January, 1947.

Captain C. S. Mehdiratte. Dated 21st January, 1947.

Captain B. V. Naidu. Dated 1st February, 1947.

Captain N. K. Sen. Dated 22nd February, 1947.

Captain B. V. Shirolkar. Dated 25th February, 1947.

Captain B. Banerjee. Dated 28th February, 1947.

Captain A. N. Lakhota. Dated 11th March, 1947.

Captain P. I. George. Dated 29th March, 1947.

Captain S. P. Bhalla. Dated 5th April, 1947.

Captain S. A. A. Sami. Dated 8th April, 1947.

Captain H. L. Banerjee. Dated 8th April, 1947.

Captain K. P. Datta. Dated 10th April, 1947.

Captain A. A. Carvalho. Dated 14th April, 1947.

Captain P. N. Menon. Dated 15th April, 1947.

Captain M. A. N. Iyengar. Dated 15th April, 1947.

Captain N. I. Sreenivasan. Dated 17th April, 1947.

Captain J. Harinarain. Dated 19th April, 1947.

Captain R. K. Moorthy. Dated 21st April, 1947.

Captain D. C. Chaudhuri. Dated 24th April, 1947.

Captain S. N. Venkataraman. Dated 25th April, 1947.

Captain B. G. Sur. Dated 27th April, 1947.

Captain S. A. William. Dated 27th April, 1947.

Captain G. S. Singh. Dated 27th April, 1947.

Captain M. Ubeidullah. Dated 28th April, 1947.

Captain S. K. Mitra. Dated 30th April, 1947.

Captain B. Mukherjee. Dated 1st May, 1947.

Captain R. N. Sharma. Dated 9th May, 1947.

Captain K. Bhaskaran. Dated 14th May, 1947.

Captain J. C. Chakravarti. Dated 15th May, 1947.

Captain S. R. Rao. Dated 18th May, 1947.

Captain J. F. Guerra. Dated 19th May, 1947.

Captain Gangasani Janardan Reddy. Dated 19th May, 1947.

Captain Syed Sayeeduddin Ahmad. Dated 20th May, 1947.

Captain Anil Chandra Das Gupta. Dated 22nd May, 1947.

Captain Sambhu Nath Datta. Dated 23rd May, 1947.

(WOMEN'S BRANCH)

Captain (Mrs.) Maude Elisabeth Khan. Dated 6th April, 1947.

Captain (Mrs.) Amy Winifred Burrows. Dated 8th April, 1947.

The undermentioned officer is permitted to relinquish his commission on release from army service and is granted the honorary rank of Captain. His services are replaced at the disposal of the Government of North-West Frontier Province with effect from the date specified :—

INDIAN LAND FORCES—INDIAN MEDICAL SERVICE
SECONDED TO THE INDIAN ARMY MEDICAL CORPS

(Emergency Commission)

Captain Abdul Azim Qureshi. Dated 14th April, 1947.

The undermentioned officer is permitted to relinquish his commission on release from army service and is granted the honorary rank of Captain. His services are replaced at the disposal of the Government of Sind from the date specified :—

INDIAN LAND FORCES—INDIAN MEDICAL SERVICE
SECONDED TO THE INDIAN ARMY MEDICAL CORPS

(Emergency Commission)

Captain Gehi Wadhu Mal Keswani. Dated 22nd May, 1946.

The undermentioned officer is permitted to relinquish his commission on release from army service and is granted the honorary rank of Captain. His services are placed at the disposal of the Government of the United Provinces with effect from the date specified :—

INDIAN LAND FORCES—INDIAN MEDICAL SERVICE
SECONDED TO THE INDIAN ARMY MEDICAL CORPS

(Emergency Commission)

Captain Bishnu Dutta Tiwari. Dated 12th June, 1946.

The undermentioned officers are permitted to relinquish their commissions on release from army service and are granted the honorary rank of Captain :—

INDIAN LAND FORCES—INDIAN MEDICAL SERVICE
SECONDED TO THE INDIAN ARMY MEDICAL CORPS

(Emergency Commissions)

Captain Tevur Ramanathaiyer Maniyan. Dated 2nd August, 1946.

Captain Parameshwaran Pillai Madhavan Nair. Dated 7th September, 1946.

Captain Attar Singh Nagpal. Dated 18th September, 1946.

Captain Anaikuppam Ramaswami Subrahmanyam. Dated 28th September, 1946.

Captain Thekevetil Ninan Chacke. Dated 17th November, 1946.

Captain Jugraj Saghavi. Dated 16th December, 1946.

Captain Vyasarpadi Loganathan Srinivasan. Dated 30th January, 1947.

Captain Abadul Ghaffar Siddiei. Dated 17th March, 1947.

Captain Bhagwan Das Kumar. Dated 29th March, 1947.

Captain Jagjit Singh. Dated 29th March, 1947.

Captain Suresh Chandra Lahiri. Dated 12th April, 1947.

Captain C. Thomas Simon. Dated 20th April, 1947.

Captain Romendra Nath Chowdhury. Dated 20th April, 1947.

(WOMEN'S BRANCH)

Captain (Mrs.) Manijeh Rustam, Tarapore. Dated 26th June, 1946.

The undermentioned officer is permitted to relinquish his commission on reversion to the Indian State Forces :—

INDIAN LAND FORCES—INDIAN MEDICAL SERVICE
SECONDED TO THE INDIAN ARMY MEDICAL CORPS

(Emergency Commission)

Captain Raghubar Chowdhury. Dated 4th December, 1946.

The undermentioned officers are permitted to relinquish their commissions on release from army service and are granted the honorary rank of Captain. Their services are placed at the disposal of the Government of Baluchistan with effect from the date specified :—

INDIAN LAND FORCES—INDIAN MEDICAL SERVICE
SECONDED TO THE INDIAN ARMY MEDICAL CORPS

(Emergency Commissions)

Captain Dhroub Parkash Kapur. Dated 22nd January, 1947.

Captain Abdul Aziz Awan. Dated 21st February, 1947.

The undermentioned officer is permitted to relinquish his commission on release from army service and is granted rank of Surgeon-Lieutenant :—

INDIAN LAND FORCES—INDIAN MEDICAL SERVICE
SECONDED TO THE INDIAN ARMY MEDICAL CORPS

(Emergency Commission)

Captain K. V. Ganapathy. Dated 24th March, 1947.

Publishers' Notice

SCIENTIFIC Articles and Notes of interest to the profession in India are solicited. Contributors of Original Articles are entitled to receive 25 reprints *gratis*; additional reprints can be obtained on payment. No reprints will be supplied unless contributors ask for them at the time of submitting their manuscripts.

The preparation of reprints entails rearranging the type, so that there is often a delay of a month or more, after the publication of the *Gazette*, before the reprints are ready. If reprints are not received within two months of publication of the *Gazette*, contributors should write to the Publishers.

Papers and articles forwarded for publication are understood to be offered to *The Indian Medical Gazette* alone, and any breach of this rule will be followed by non-publication. When any such article appears in *The Indian Medical Gazette*, the copyright automatically becomes the joint property of the author or authors and of the publishers.

Communications on Editorial Matters, Articles, Letters and Books for Review should be addressed to THE EDITOR, *The Indian Medical Gazette*, c/o The Calcutta School of Tropical Medicine, Central Avenue, Calcutta.

Communications for the Publishers relating to Subscriptions and Advertisements should be addressed to THE PUBLISHERS, *The Indian Medical Gazette*, P. O. Box No. 54, Calcutta.

Annual Subscription to 'The Indian Medical Gazette', Rs. 16 including postage, in India. Rs. 19-8 including postage, abroad. Single copies Re. 1-8 each. Back numbers (if available) for the previous year Rs. 2-8 each, and all other back numbers Rs. 5 each.

The Editors of *The Indian Medical Gazette* cannot advise correspondents with regard to prescriptions, diagnosis, etc., nor can they recommend individual practitioners by name, as any such action would constitute a breach of professional etiquette.

HYPOPROTEINÆMIA DUE TO UTILIZATION OF PLASMA PROTEIN FOR ERYTHROPOIESIS

By C. R. DAS GUPTA, M.B., D.T.M. (Cal.)
and

J. B. CHATTERJEE, M.B.

Assistant Research Worker, Haematological Unit, Indian Research Fund Association

(From the Department of Haematology, School of Tropical Medicine, Calcutta)

RECENT studies on blood protein in cases of nutritional macrocytic anæmia show the incidence of hypoproteinæmia in some of the untreated cases*. In the cases responding well to treatment with hæmatinics, with or without transfusion, along with clinical and hæmatological improvement, there is increase of the blood-protein level as well. The case cited below was an exception. This was a case of severe macrocytic anæmia of pregnancy. Hæmatinics and transfusion of blood raised the blood picture from very low levels to almost the normal level in about a month. But contrary to expectation the patient's clinical condition, particularly the œdema, did not show proportionate improvement in the early stage and the œdema increased still further and spread all over the body in the later stages without any falling off of blood values. Estimation of blood protein in the later stages showed great reduction of total protein which was due mostly to the reduction of the albumin fraction. No treatment was of any avail in reducing the œdema or increasing blood protein, and with the blood picture maintaining the high level, the case closely simulated the clinical entity called 'malignant malnutrition' (Trowell and Muwazi, 1945). The patient died within a few months.

During recovery from anæmia generalized œdema due to hypoproteinæmia was noted in a vegetarian by Holmes (1944) and in a case of pernicious anæmia with faulty dietetic habit by Davies (1945). In both the cases the condition was relieved with transfusion of plasma and change over to high protein diet. Thus, these two cases differed materially from the case cited below which, as mentioned above, terminated fatally in spite of all treatment.

Case note

Mrs. S. D., 33, multipara, belonging to lower middle-class, was reported to be a chronic sufferer from diarrhœa for over 2 years and was reported to have had an attack of malaria in 1943. She was admitted into the Carmichael Hospital for Tropical Diseases in 1944 for her diarrhœa. Repeated examinations of the stool failed to

show any pathogenic organism. Her diarrhœa was however brought under control and she was discharged as a case of nutritional diarrhœa. After discharge from the hospital she had occasional bouts of diarrhœa.

The patient became pregnant in April 1945 and it was reported that before her conception she was in indifferent health and had also some degree of anæmia. With the progress of pregnancy her anæmia increased and later she developed some œdema. She was admitted into Chittaranjan Seva Sadan on 16th December, 1945, where she was delivered of a male child on 18th December, 1945. Reports from Seva Sadan indicated that she was very anæmic and had œdema all over the body; she was also running a low intermittent temperature. Treatment with hæmatinics and two blood transfusions for about a month did not improve her condition and she was transferred to the Carmichael Hospital for Tropical Diseases on 19th January, 1946, for the treatment of her anæmia.

On admission, the patient was found to be distinctly orthopneic with visible carotid pulsations. She had a distressing cough but expectoration was scanty. The general condition of the patient was very low and she was running a slight temperature. The patient looked very pale, the face was slightly puffy and she had moderate degree of œdema over the feet and legs and slight œdema in the sacral region.

The spleen was enlarged about one inch below the costal margin and the liver was also enlarged about one inch and was slightly tender. The heart was slightly dilated and hæmic murmur was audible over the pulmonary area. The pulse was of water-hammer type and the blood pressure was 106/35. Fine crepitations were heard over the interscapular region of both sides.

Laboratory and other findings :—

Blood :

Blood picture	.. See table and graph
Blood proteins	.. See table
Blood cholesterol	.. 0.070 per cent
Blood urea	.. 0.0232 "
Aldehyde test	.. Negative "
Complement-fixation test for kala-azar.	.. "
Wassermann reaction	.. "

Stool.—Nothing abnormal found on repeated examinations.

Urine.—Repeated examinations showed only traces of albumin.

Sputum.—No acid-fast bacilli on repeated examinations.

Skiagram of the chest.—No lung infiltration seen.

Fractional gastric analysis.—Hypochlorhydria.

Treatment.—See graph.

Progress

With transfusion of blood and hæmatinics the blood picture improved very rapidly from the

* Unpublished observations.

very beginning and reached a high level in about a month and showed still further improvement later on. With the improvement of blood picture

pickles (*achár*) and fried rice (*mudi*). Strict vigilance on her diet and a course of enterovioform helped to control the diarrhoea,

BI = Blood. PI = Plasma. S = Serum. P.H. = Protein hydrolysate.

the patient's general condition improved considerably, the patient was no longer orthopneic and the cough was not distressing. But even then the clinical improvement was never proportionate to the hæmatological improvement. The œdema after slight initial improvement was found to be increasing again after the third week and gradually the œdema spread all over the body and there was fluid in the peritoneal cavity

The slow intermittent temperature was completely off by the third week and thereafter the patient continued to be afebrile.

On account of persistent œdema, the blood protein examined again by the copper sulphate method and later by microkjeldahl method was found to have gone down considerably below the level found on admission with marked fall in albumin fraction (*see table*).

TABLE

Date	R.B.C. (millions)	Hb. (gramme)	M.C.V. (cu. μ)	W.B.C. (thousands)	PROTEIN			Treatment
					Total (per cent)	Albumin (per cent)	Globulin (per cent)	
21-1-46	0.77	3.16	149.4	7.8	5.4	2.9	2.5	See graph.
1-2-46	2.02	6.18	103.9	
22-2-46	3.40	11.5	105.9	7.7	
13-3-46	3.78	12.5	97.8	7.4	3.0	
17-4-46	3.95	13.4	103.8	5.7

12-5-46	3.90	13.2	

as well. No treatment was of any avail in reducing the œdema which persisted till the very end.

The initial diarrhoea was brought under control with sulfaguanidine, later she again developed diarrhoea which did not improve with sulfaguanidine. It was then detected that the patient was surreptitiously taking

Discussion

The most notable clinical feature in this case was that though the blood picture improved rapidly with hæmatinics and transfusion of blood, in fact, more rapidly in the early stages than is usually seen in similar cases of macrocytic anæmia of pregnancy, the œdema, after slight initial improvement, began to increase

again after the third week of treatment, when the blood values were still increasing. From that time the oedema increased more and more and spread all over the body though the blood picture continued to be within the normal range. On admission, with a red cell count of only 0.677,000 per c.mm. and with hæmoglobin value of 3.16 gm., the total blood protein was only slightly below the normal range. Estimation of blood protein at a later date, when both the red cell and hæmoglobin had reached almost the normal level, showed marked hypoproteinæmia with greater reduction of the albumin fraction and consequently an altered albumin-globulin ratio. This would explain the recrudescence of the oedema, but what could be the pathogenesis of the development of the hypoproteinæmia, which afterwards turned out to be one of malignant hypoproteinæmia, if we may use the term. Infection as a cause of the lowering of the plasma protein can be ruled out on clinical grounds and on negative laboratory and x-ray findings. Is it then possible that the unusually brisk erythropoiesis, the increase of red cells at the rate of 0.125,000 per c.mm. and of hæmoglobin at the rate of 0.3 gm. per diem for the first ten days in such a patient, was possible only at the cost of the plasma proteins with consequent lowering of the plasma proteins? That this was not only probable but quite feasible will be seen from the works of Whipple (1938, 1942). Whipple contends that 'the reserve stores of protein-building materials from which the body can manufacture hæmoglobin, plasma protein or cell protein are largely in the form of protein within cells' and 'that liver is actively concerned in the production of plasma proteins and of the globin', which constitute the bulk of the protein content of the hæmoglobin. 'These reserve stores may be reduced to low levels by fasting or a long period of low protein diet or reduced practically to zero by long-continued anæmia or by plasma depletion during periods of low protein diet'. Whipple envisages that 'food through amino-acids contributes to the cell proteins of liver-muscle and body tissues. The liver cell (and its protein) contributes directly to plasma protein and hæmoglobin. There is an important protein exchange which may go on within the body'. 'The plasma protein contributes easily to body protein needs (muscle, liver and hæmoglobin)', but 'other tissues can contribute only with difficulty to plasma protein by this method of exchange (after the reserve stores are depleted). Other tissues contribute easily to hæmoglobin (for example, in fasting) but hæmoglobin can less readily if at all contribute to other body proteins'. Convincing proof of the theory that hæmoglobin may be formed with the help of plasma protein is afforded by the experiments on fasting anæmic dogs. Whipple (1942) concludes that 'hæmoglobin in its production may draw on the plasma protein but hæmoglobin stands apart in the protein economy and does not contribute freely to the protein pool. On

the other hand, the body guards jealously the fabrication of hæmoglobin and, given a real need for both plasma protein and hæmoglobin, the protein flow favours hæmoglobin, which under these circumstances always is produced in more abundance than the plasma protein'.

On the basis of Whipple's theory, the development of hypoproteinæmia in the reported case could be explained in the following way: The reserve store of protein-building material was brought to a very low level, may be to zero level, by long-continued anæmia together with the restricted diet on account of diarrhoea and finally by loss of blood during childbirth. The brisk hæmopoiesis, following liver therapy at this stage, could only be possible from utilization of the plasma protein more so as the patient could not or rather would not take sufficient protein by mouth on account of diarrhoea. The recrudescence of the oedema just at the end of the brisk erythropoiesis would lend support to this. Continued improvement in the blood picture in the absence of sufficient protein diet was responsible for further lowering of the plasma protein, which later was found to have gone down to very low level with altered albumin-globulin ratio.

Summary and conclusion

In response to the stimulus of potent liver extract hæmoglobin and red cells were formed in great abundance in a very debilitated case of macrocytic anæmia after confinement. The increase in the hæmoglobin and red cells was followed by fall in the plasma protein to a very low level from which it could not recover. It has been suggested that the lowering of the plasma protein was due to utilization of plasma protein for the formation of hæmoglobin. For, it has been argued that on account of the depletion of the protein reserve of the body, and in the absence of sufficient protein from the food, formation of hæmoglobin could only be possible by utilization of plasma protein, a not too unusual procedure under certain conditions.

FURTHER OBSERVATIONS ON PLAGUE

By A. T. W. SIMEONS, M.D.

Director of Health Services, Kolhapur State
and

K. D. CHHATRE, M.B., B.S.

Assistant Director of Public Health, Kolhapur State

In the June-July 1946 number of the *Indian Medical Gazette* we published a report on

1,000 cases of bubonic plague treated in an emergency plague hospital. Here we deal with a further 700 cases treated with sulfamerazine, the value of inoculation, our experience with temporary village plague hospitals and general anti-epidemic measures.

Sulfamerazine in bubonic plague

During the period from July 1946 to January 1947, 700 consecutive cases of bubonic plague were treated in the Kolhapur Plague Hospital with sulfamerazine.* From the outset sulfamerazine appeared to have the great practical advantage that the interval between doses can be prolonged to eight hours instead of four hours as with sulfadiazine. In an overcrowded emergency hospital this very considerably reduces the work of the staff administering the drug. Thus even if sulfamerazine showed no clinical superiority over sulfadiazine it would still remain the drug of choice.

Apart from the variations in dosage described below, all patients received the same general nursing care. Great attention was again paid to an ample intake of fluids, but instead of doing this by the intravenous route, as in a previous series, we generally gave unconscious patients fluids (normal saline-glucose) by nasal catheter. This we found to be most satisfactory if started before there were any signs of collapse and it was, of course, simpler, quicker and much cheaper.

We started with a series of 100 consecutive cases of bubonic plague in which we gave no injections. The dose of sulfamerazine was: initially six tablets (3 grammes), then two tablets six hourly. In this series we had 19 deaths of which 6 were moribund (i.e. death within 24 hours of admission). The average duration of fever was 3.6 days among recovered cases and the average duration of hospitalization was 7 days. We gathered the impression that the effect on the temperature was not as prompt as we had been accustomed to see after sulfadiazine injections. We also noticed that the buboes became exceedingly painful from the second day of treatment onwards, a phenomenon we had not previously observed. We further experienced retention of urine in a much larger percentage of cases than previously observed. We attributed this to the very high dose of sulfamerazine which was in excess of that advised by the manufacturers.

For these reasons we changed our dosage schedule in the next 100 cases to one injection of $2\frac{1}{2}$ grammes in 50 c.c. of glucose intravenously on admission and then two tablets eight hourly instead of six hourly as in the previous series. In this series we had 15 deaths of which 6 were moribund and 9 non-moribund. The average duration of fever was 3.2 days and the average

duration of hospitalization was 6.3 days. The results of this schedule were therefore slightly better than in the first series. Retention of urine occurred only in a single case. We attributed these better results to the rapid action of the intravenous injection and to the decrease in dosage.

Having convinced ourselves of the advantage of an initial injection we again changed our schedule in the next 100 cases to two injections eight hours apart, the first of 2.5 grammes and the second of 1 gramme and continued with one gramme of the drug orally given at eight hourly intervals. In this series there were only 12 deaths of which 4 were moribund and 8 non-moribund. The average duration of fever and the average stay in hospital were 2.7 days and 6.1 days respectively, thus showing an improvement over the first and second series. As our figures appeared to improve with the number of injections given, we tried a few cases giving four to five injections without any oral treatment. Though in these cases the temperature came to normal they all relapsed after a few days and had to be treated again with injections and tablets. We, therefore, abandoned work along these lines and tried another series of 100 cases with three injections, initially 2.5 grammes then two injections of 1 gramme each eight hourly after which tablets (one gramme per dose) were given eight hourly. In this series we had 14 deaths of which 4 were moribund and 10 non-moribund. Though this result was not quite as satisfactory as in the previous series as regards the mortality we were none the less impressed with the rapid fall in temperature and the control of toxic symptoms both of which appeared to be better than in the two-injection series. We, therefore, decided to continue on this schedule and treated 400 consecutive cases in this way. In this series of 400 cases the average stay in hospital of recovered cases was 5.9 days and the average duration of fever 3.3 days. The total mortality was 14 per cent and the non-moribund mortality was 7.2 per cent. We observed no toxic effects attributable to the drug: there were no rashes and no urinary complications. Though the average duration of fever worked out to 3.3 days, the majority of cases was normal within 24 hours; the high average is due to the inclusion of some cases with extensive cellulitis and severe hæmorrhagic cases in which the temperature took a long time to subside completely.

Sulfamerazine versus sulfadiazine

In our previous work with sulfadiazine we found a total mortality of 18 per cent and in non-moribund cases 8 per cent while sulfamerazine (three-injection series) showed a total mortality of 14 per cent and 7.2 per cent in non-moribund cases. There thus appears to be a slight (perhaps not statistically significant) superiority of sulfamerazine. It must, however, be pointed out that in our sulfadiazine cases we

* Messrs. Sharpe & Dohme very kindly placed at our disposal, free of charge, all the sulfamerazine we required.

used far more than three injections. Apart from the recorded facts the clinical observation of cases distinctly gave us the impression that sulfamerazine is superior; that in the dosage used in the last series the initial drop in temperature after the beginning of treatment was more rapid. The great advantage of a longer spacing between doses has already been stressed.

Fig. 1.

Figure 1 shows a comparison between the mortality rates of hospitalized patients treated with sulfathiazole, sulfadiazine and sulfamerazine. It is significant that in the sulfathiazole group the majority of cases was from Kolhapur City and that later cases in the sulfamerazine group were mostly from outlying rural areas and frequently admitted in a collapsed condition after a long journey. We are inclined to believe that all other factors being equal sulfamerazine would show a more marked superiority than our figures indicate. That under these circumstances there is a decline in moribund deaths can only mean that a larger number of cases could be made to survive the first 24 hours. It is also significantly in favour of sulfamerazine that in this group the percentage of inoculated cases was lower than in either of the others.

We are satisfied that sulfamerazine used according to our last schedule is, so far, the drug of choice in the treatment of bubonic plague.

Village plague hospitals

The more popular the Kolhapur Plague Hospital became the longer became the distance that patients travelled to seek admission and the more clear it became to us that a long and difficult transport after the onset of plague lowered the chances of recovery very considerably. Generally speaking, our moribund cases were ones that had been transported from a long distance before admission. Once this was clearly realized that we decided to start temporary emergency village plague hospitals in the middle of affected areas so that patients could be admitted without the dangers of a long transport, usually in a bullock cart. In two such temporary village hospitals a total of 316

patients was admitted. Among these there were 31 deaths, representing 10 per cent mortality. Of these, 13 were moribund and 18 non-moribund. The non-moribund mortality was therefore only 6 per cent. All these cases were treated with sulfadiazine. It is interesting to note that these results, achieved under very primitive village conditions, are even better than those of the city plague hospital; entirely, we think, due to the fact that these cases were admitted from a radius of only a few miles which may also account for the low number of moribund cases (4 per cent of total admissions compared with 11 per cent in the Kolhapur City Hospital).

It does, therefore, seem to be of the greatest importance to bring adequate facilities for treatment right into the midst of an affected area and to have a number of such emergency field hospitals rather than to concentrate the cases in a large central hospital situated possibly at some considerable distance from the affected area. We shall refer to these village hospitals again further on.

The value of inoculation for improving the chance of recovery

Among a total of 2,753 cases treated in the hospital there was a total mortality of 17 per cent and a non-moribund mortality of 8.5 per cent. Of these 2,753 cases, 1,400 were inoculated and 1,353 were uninoculated. Among the uninoculated the total mortality was 21.2 per cent and among the inoculated it was 12.9 per cent. Similarly the non-moribund deaths were 10.8 per cent among uninoculated and 6.3 per cent among inoculated (see figure 2). Contrary to our fears

Fig. 2.

expressed in a previous paper, the analysis of a much larger series does, therefore, show that inoculation, to some extent, enhances the chances of recovery.

In order to demonstrate the relation of the lapse of time between inoculation and attack and the improved chance of recovery we have in figure 3 plotted the total mortality rates per cent against the period between the date of inoculation and the date of attack. This figure

confirms our previous view that between the first and second week after inoculation the mortality is very high. During the third week the mortality drops to its lowest and after six months

it returns to the level of the uninoculated. The fact that the mortality in the first week is unexpectedly low might indicate that inoculation, i.e. during the incubation period, boosts an immunity mechanism which has already started to function; but that an infection acquired during the 'negative phase' caused by the inoculation, i.e. shortly after inoculation, is particularly virulent.

If practical conclusions can at all be drawn from our limited material they would be: first to refrain from inoculating immediately exposed persons such as those living in the close vicinity of a case and secondly to set the period of increased resistance after inoculation at a maximum of 4 months for a single injection.

General anti-epidemic measures

Since our earlier report in which we emphasized the value of cyanogas, considerable further studies have led us to modify our views.

We have on several occasions seen that cyanogassing a whole plague-affected village with the utmost care and thoroughness combined with the use of kerosene-soap emulsion has had disastrous result never observed in the city where the whole inhabited area could not be covered in 2 to 3 days. Within 2 weeks of our enthusiastic efforts we have seen a sudden and alarming rise in incidence occur in such thoroughly treated villages. The only explanation is a too radical destruction of rats and the merely ephemeral effect of kerosene-soap emulsion on fleas.

We, therefore, decided to use D.D.T. on a large scale. In this we were handicapped by a severe shortage of kerosene though we had ample crude D.D.T. available. At first we tried to blow D.D.T. dust on the floors. This did not work because as soon as the squad turned their

backs the floor would be swept 'clean' by the house-owner. It was, therefore, decided to mix crude D.D.T. in a proportion of 1 in 4 with fresh cowdung and to spread this mixture in the usual way on the floors of village houses. A few pilot experiments in the laboratory had shown this mixture thinly spread to be rapidly lethal to rat fleas. This method, though very wasteful in D.D.T., proved to be the most successful we have so far employed. We have collected dead fleas in large numbers from rooms treated in this way. After the second or third day it was hard to find more fleas but the floors continued to be lethal to other insects as long as the house-owners could be prevented from applying a fresh coat of dung containing no D.D.T. Now that water miscible D.D.T. is available the kerosene and the transport difficulties are solved and we can at last apply it to floors and walls with sprayers.

We consider it the ideal routine in plague control to treat the focus of an outbreak with D.D.T. at once and intensively and to do no rat-baiting or inoculation in the focus. The surrounding unaffected villages, however, should be inoculated (if funds and staff permit) and in any case subjected to intensive anti-rat measures and given a blanket D.D.T. treatment of all houses, if the village is near, or in direct communication with, the affected one.

The occurrence of 10 simultaneous plague cases in one locality within a 4-mile radius we consider sufficiently serious to call for the immediate establishment of a village plague hospital which can be opened within a few hours and which closes down as soon as no further cases are reported. These village hospitals are run by doctors deputed from the Kollhapur Plague Hospital who have had special training. The villages provide room, furniture and menials and pay for drugs, food, etc., from voluntary contributions or village funds. Our difficulty has not been to get such hospitals going, on the contrary we have often had to dissuade village enthusiasts from opening a hospital for an occasional sporadic case. We usually select a hall in which men, women, children and all castes and creeds are accommodated together in order to save staff and make supervision easier. The fact that there is no criticism of this arrangement and that the villagers are intensely proud of their recovery records and gladly admit outsiders from adjoining non-State territory to 'their' hospital is certainly encouraging evidence of 'rural uplift'.

Where such measures are adopted we discourage the villagers from leaving their houses and camping in the fields, because our experience shows that the incidence of plague among those that have fled is usually higher than among those that have stayed at home, safeguarded by D.D.T.

Of all these measures we consider inoculation the least important; it is by far the most expensive and enjoys none of the universal

popularity of the other measures. Particularly the blanket D.D.T. treatment has an incredible effect on village morale owing to the incidental riddance of bedbugs, flies and other pests for which the villagers are intensely grateful.

As it has been possible to apply these measures to all outbreaks occurring in the State, the population have, to a very great extent, lost their dread of plague. They have come to look upon it as a severe but brief illness from which one generally recovers and which is far less serious than typhoid. It is easily recognizable and our villagers now know exactly what to do. Forty-eight hours' delay between the reporting of a case and the arrival of an anti-epidemic squad, even in remote villages, usually results in a formal deputation politely suggesting gross inefficiency on the part of the Health Department, a welcome sign indeed. The complete absence of panic makes sanitary measures much easier to apply. Plague is rapidly becoming a controllable disease. It is still very expensive to control, but the old attitude of helpless horror is fast waning.

Summary

1. Sulfamerazine, the drug of choice, in the treatment of bubonic plague.
2. The importance of emergency village hospitals.
3. Inoculation to some extent improves the chances of recovery, particularly during the 2nd, 3rd and 4th months after inoculation.
4. The danger of too thorough rat-destruction.
5. D.D.T. in rural plague control.

Acknowledgments

Our particular thanks are due to Dr. G. B. Pawar, Assistant Director of Public Health, and Dr. V. K. Altekar, Epidemic Officer, Kolhapur State, who were responsible for all the work in the field and to the enthusiastic plague hospital staff.

BLACKWATER FEVER

By A. K. NANDI, B.Sc., M.B. (Cal.), L.R.C.P. & S. (Edin.),
M.R.C.P. (Edin.)

Teacher of Medicine, Dacca Medical School, Dacca

DURING the period of my service for the last six years at Jalpaiguri I had opportunities to see quite a large number of cases of blackwater fever. The disease is very prevalent in Duars of Jalpaiguri, Terai of Darjeeling and also moderately in other parts of Bengal.

Economic loss to the population due to this disease is not inconsiderable. Loss of earning *per capita* due to death is a small factor, but the greatest loss sustained is due to disablement after an attack of blackwater fever. The victim is in constant dread of a relapse and leads a life of semi-invalidism, unable to work hard and earn as much as a healthy man.

The worst sufferers are middle-class people, who are to work hard, often pass sleepless nights and are careless about their diets. They are generally constipated, often suffer from mild attacks of malaria which they generally ignore or at least treat with only occasional doses of quinine. On the other hand, the poorer class, the tea garden coolies and the Santhal cultivators of Duars, who are in the habit of taking daily 'panchai' (fermented rice) and 'toddy', are comparatively free from this disease, though they often suffer from recurrent attacks of malaria. It may be that 'panchai' and 'toddy' contain vitamin B which may play some rôle in the prevention of blackwater fever and opens a field for investigation. The Europeans of Duars and Terai are also comparatively immune, although they stay there for years together and take quinine almost daily along with whisky, brandy or beer.

The onset of the disease is always very sudden. There is chill and the patient takes a few grains of quinine salt and to his horror he finds that he is passing tarry black or deep red urine. Incessant vomiting sets in, the skin and the conjunctivæ of the eyes become canary yellow, and the patient becomes very restless and writhes in agony. The consciousness is never lost and the mind is clear up to the end. The temperature rises up to 102°F. or more. As long as urine is passed in good quantity, be it black or light coloured, there is every chance of recovery. If it stops and hiccough starts, the situation is extremely grave. The suppression of urine may continue till death or after sometime, 2, 3 or 4 days or longer, there may be free urination and the patient's life is saved. In a case of mine there was total suppression of urine for as long as seven days during which period the patient did not pass a drop of urine in spite of all possible treatment, and then all of a sudden, after seven days, he passed about 2 pints of clear urine and the crisis was over.

The suppression of urine is not necessarily due to mechanical obstruction of the kidney tubules, but may be due to temporary suspension of the activities of the kidneys allied to shock.

It is a self-limited disease, generally curing itself. Sometimes a course of slight fever comes in the wake which is often refractory to all treatment and ultimately leads to the death of the patient.

The disease never confers immunity. Relapses are common. It is quinine that precipitates attacks.

The havoc wrought on different organs of the body is not inconsiderable. Massive destruction of red blood cells is a special feature. The liver tries to put a check to it by sending out lipoids and reconverting lost iron into corpuscles. Soon it gets overworked and shows signs of necrosis. Heart suffers from malnutrition due to less number of oxygen carriers and the increased blood acidity leads to the injury of the heart.

muscle. The kidneys try to eliminate the stroma of broken red cells and also the excess of accumulated acids. They get enlarged, tubules are degenerated, and filter heads clogged with stroma and hæmoglobin infarcts.

Treatment

1. Hydrarg subchlor in fractional doses with chloretone and ice to suck give the best result in checking vomiting.

2. Injection of atebirin and plasmoquin.

It is questionable if they are at all indicated in blackwater fever. They can be given with good result only when the blood shows malarial parasites. On the other hand, we have seen that blackwater patients, who are generally very much afraid to take quinine (and I think that they are justified) during their subsequent attacks of malaria, have often developed blackwater fever after taking atebirin and plasmoquin. So I think they are not absolutely safe as has hitherto been considered.

3. Injection of pedunculine or vitex peduncularis by mouth.

As there is excessive vomiting, we prefer injections. Pedunculine 3 c.c. intramuscularly or intravenously once or twice a day gives very good result and often produces free diuresis.

4. Glucose and sodi bicarb.

As there is damage to the kidneys, I prefer 5 per cent glucose solution 100 to 200 c.c. with sodi bicarb 7½ per cent 25 c.c. intravenously once or twice daily for loss of fluid and increased H ion of the blood and to maintain the heart.

5. Salines—subcutaneously, intramuscularly, intravenously or per rectum—are highly advocated in textbooks for the treatment of blackwater fever. But are they justifiable in view of the fact that inflammatory changes occur in the kidneys with chloride retention in some cases and do they not cause more damage to the kidneys?

Plenty of fluid in the form of plain water, dab (green coconut) water and glucose water should be given for dehydration.

6. Calcium, vitamin C and vitamin K have been freely introduced as adjuvant treatment.

7. Penicillin.

In November and December 1946 there were several cases of blackwater fever in Gooshkara (district Burdwan) and I was told by the attending physicians of the locality about the high mortality of the blackwater fever cases there. Thorough investigations were made in two cases which I saw—they were real blackwater fever cases and both were highly toxic. But the blood count in one was 14,000 white cells and 85 per cent polymorphonuclear cells and in another 13,000 white cells with 91 per cent polymorphonuclear cells, although I could not detect any inflammatory evidence anywhere clinically. Penicillin was tried—20,000 units intramuscularly every three hours, total 600,000 units in one case and 1,000,000 units in the

other—along with intravenous glucose and sodi bicarb. One case rallied in a week but the other took one month for complete recovery.

It is too early to say anything definitely about the rationality and efficacy of penicillin treatment of blackwater fever, but as I was very much impressed with the results I have thought them worth recording.

8. Blood transfusion.

Only in one case it was possible—about 500 c.c. were transfused—the patient survived.

9. For suppression of urine, alkalies in massive doses, plenty of bland diluents to drink, hot fomentations and application of anti-phlogistin or linseed poultice over the loins, dry cupping, continuous rectal administration of alkalies and 5 per cent glucose by drip method, intravenous injection of 5 per cent glucose 100 to 200 c.c., and in suitable cases injection of caffeine sodium benzoas may all be tried.

10. After infection fever is very hard to control. Mixed vaccines, iron and liver extract have done some good in many cases.

Sudden failure of the heart is baffling to the physicians. The patient apparently cured may drop down dead as soon as he attempts to sit on bed. It may be due to coronary blocking owing to formation of intravascular clots after liberation of a large quantity of thrombokinase from massive destruction of red blood corpuscles or due to damaged myocardium.

It is now admitted that H ion poisoning is the main factor for extensive hæmolysis. If it were so, blackwater fever could be induced by injecting any acid or by giving any acid by mouth. If hæmolysis were due to quinine alone acting as a detonator, then quinine has something to do with the hæmolysins produced somehow in the blood and may be working in combination. It may be that at certain stages of sporulation of malarial parasites a large quantity of hæmolysin is produced which is perfectly neutralized where the blood is in physiological state. These are some of the doubts that come upon the present conception of blackwater fever which future workers may be in a position to clear.

TREATMENT OF AMŒBIC DYSENTERY WITH E.B.I. RETENTION ENEMAS

By S. J. GROSS, M.D.

Chirala, M. and S. M. Ry.

AMŒBIC dysentery is an infection of the colon with *Entamœba histolytica* (EH) which, except in cases of metastatic abscesses, very seldom resides in other organs. The colon is normally inhabited by a number of other bacteria. It is beyond the scope of this paper to discuss the rôle of these bacteria in the pathology of amœbiasis. However, it has to be mentioned that the amœbæ grow better in the presence of certain bacteria and that, to my belief, certain symptoms generally ascribed to the amœbic

infection are caused by these bacteria. The latter enter the organism *via* the intestinal lesions caused by the amoebæ, and may produce a *B. coli* sepsis for instance. None of the various drugs and methods advocated for the treatment of amoebiasis has given complete satisfaction. The oral drugs like the arsenic and quinoline compounds do not eradicate the infection, emetine injections do not affect the cysts, and emetine-bismuth-iodide combined with the chiniofon enemas requires hospitalization. The ideal would be an ambulatory treatment.

It has been established that *in vitro* emetine is an excellent amoebicide, but does not affect the cysts of *EH*. Emetine-bismuth-iodide has the advantage that it also destroys the cysts. Therefore, these drugs should give excellent results in the treatment of amoebic dysentery, provided they are given in the proper manner. This led to a reconsideration of the usual methods of treatment.

Parenteral route.—Emetine is given by injections. In this manner only a small fraction of the drug can, and will, reach the colon where its action is desired. A greater portion will be distributed all over the body. Thus it will affect also healthy tissue, as emetine is a plasma poison, and the toxic effects of emetine are well known. On the other hand, investigations by Laidlaw, Dobell and Bishop have shown that even such a small concentration of emetine as 1 : 5,000,000 was lethal for *EH in vitro*, if it were in constant contact for a period up to 4 days, and provided that the medium did not become too acid. In later experiments Dobell grew amoebæ in a culture containing one strain of bacteria only. There he found that the amoebæ were unable to survive for 3 or 4 days in emetine concentrations of less than 1 : 5,000,000.

Oral route.—Only a small portion of the drugs given by mouth will reach the colon where their action is desired. A greater portion will be absorbed in the intestinal tract or be transformed by the digestive secretions. In this connection I want to cite Manson-Bahr: 'From observations made by sigmoidoscopy it has been found that the most intense amoebic ulceration is present in the sigmoid colon and in the lower part of the rectum, in a position where it is improbable that *E.B.I.* can any longer exert its full action'.

Rectal route.—In view of the above it has to be concluded that the best method would be to introduce the medicaments directly into the colon and rectum. Manson-Bahr attempted to introduce emetine directly into the bowel. This caused a considerable amount of pain and was by no means successful. 'When given in a dilution of 1 : 4,000 (4 grains of emetine in 10 oz. of normal saline) violent spasms were produced and a parasitic relapse of amoebic dysentery with blood and mucus in the stools ensued.' I contend that this treatment was unsuccessful for

the following reasons. Nobody would ever dare to give a single injection of 4 grains of emetine as this would be too toxic. The drastic action had to be expected, because emetine being a plasma poison will in this concentration damage also the healthy tissue of the bowels. The strong concentration of emetine will cause irritation and subsequently there will be diarrhoea with mucus and blood from vessels which have been damaged.

I gave emetine-bismuth-iodide (*E.B.I.*) as retention enema, and after trial and error I arrived at the following formula for the retention enemas:—

R Emetine-bismuth-iodide	1 gr.
(or			
Kurchi-bismuth-iodide	1 gr.
plus Emetine	$\frac{1}{2}$ gr.)
Sulfonamide	10 gr.
Sodium bicarbonate	10 gr.
T. opii	5 mins.
Tragacanth or gum	5 gr.
Water	ad	..	1-2 oz.

Comment.—At first I used only *E.B.I.*, and when I could not get it any more, I tried kurchi-bismuth-iodide (*K.B.I.*), but the results with *K.B.I.* were disappointing. Therefore, I added a $\frac{1}{2}$ grain of emetine to *K.B.I.*, as $\frac{1}{2}$ grain is roughly the amount of emetine in 1 grain *E.B.I.*

The results with *K.B.I.* plus emetine were subsequently as good as with *E.B.I.* The sodium bicarbonate was added because emetine acts best in an alkaline medium. Sulfonamide was given to inactivate the intestinal bacteria which might support the growth of the amoebæ as these grow better in the presence of certain bacteria. Moreover, the sulfa drugs will be useful against an eventual concomitant *B. coli* infection. *T. opii* was added because in some cases the enemas caused irritation and cramps. Tragacanth was needed to suspend the drugs like in an emulsion, and to prevent that the drugs are reabsorbed too quickly from the bowels.

The enemas were given after defecation so that its contents should not be absorbed or diluted by the fæces, and to ensure that the drugs come into direct contact with the wall of the bowels. A fairly even distribution of the enema can be assumed, as peristalsis and anti-peristalsis will move the contents of the colon forwards and backwards. I have the impression that the enema forms a film all over the colon, because pains indicating a lesion in the area of the cæcum were also relieved with this method. The enemas were given daily for 8 days; 8 administrations constituting one course. All patients were treated as out-patients. No special diet nor directions were given during treatment, except that I gave vitamin B to some patients who were rather weak and where it was feared that the sulfas might interfere with the absorption of vitamin B from the intestines. All patients were able to continue their work. In a number of cases retention enemas proved successful where all other treatments had failed.

The majority were relapsing or chronic cases. All patients who were still positive after the first course, whose motions still contained *EHs* or cysts, were given a second course after an interval of 4 days.

The following cases may serve as an illustration :—

Case 1.—Mr. A. C., 31 years old, complained of flatulence, weakness and abdominal pains, most painful points being cæcum and sigmoid. Microscopical examination of the stools showed *EHs* and cysts. Patient was given a course of emetine injections and simultaneously enterovioform by mouth. Patient felt subjectively better, but re-examination of the motion still revealed cysts. Some weeks later he complained again about pains. He was now given E.B.I. retention enemas for 8 days. During the first 3 or 4 days patient reported diarrhoea with mucus and abdominal cramps. These symptoms subsided gradually. After 8 days still cysts were seen in the stool. Four days later he was given another course, and this time there were no manifestations. At the end of the second course which was tolerated much better, all his symptoms disappeared, and repeated examinations did not reveal any *EHs* or cysts.

Case 2.—Mr. C. R., 43 years old, had a history of hookworm infection and of gastric ulcer. He complained of vague pains round the umbilicus. Cysts were found in his stool. He was treated with enterovioform, but though the symptoms improved, a control examination showed cysts to be still present. Patient was then given a course of E.B.I. retention enemas. At the end of this course cysts and *EHs* were found in his motions. A second course was given, and thereafter the stool was free of *EHs* and of cysts. The patient was re-examined at regular intervals, but no parasites were found nor did he have any further complaints.

Case 3.—Mr. E. K., 39 years old, gave a history of pains in the left groin. He had been under medical treatment for a long time. As the patient did not improve with any treatment given, his stools were examined and cysts found. After a course of emetine and of enterovioform, he was slightly better, but parasites were still present. Several ulcers were seen on rectoscopical examination. Kahn positive. Patient was then put on N.A.B. injections, and simultaneously he was given E.B.I. retention enemas. A subsequent stool examination showed *EHs* and cysts. A second course was given, but stool remained positive. After an interval of 8 days he was given a third course, the enemas having double strength, together with stovarsol tablets by mouth. However, this too proved unsuccessful. This patient continued to have *EHs* and cysts in the faeces for all the time he was under my observation, i.e. 15 months, and had periodical relapses of his symptoms in spite of all the treatments given to him.

Case 4.—Mr. C. E., 30 years old, gave a long history of gastro-abdominal complaints and had

been treated for gastric ulcer. Radiological examination did not show any gastric lesion, but on stool examination cysts were found. He got temporary relief from emetine injections, but stools continued to remain positive. Patient was then put on E.B.I. retention enemas, and his motions became free from parasites after the second course only. After the last course he made a speedy recovery and began to put on weight.

I have treated 64 cases of amœbiasis with E.B.I. retention enemas and the results are given in the table.

64	EH, C +	C +	C +	Cysts persisting.

EH = *Entamoeba histolytica*.C = Cyst of *Entamoeba histolytica*.

Many of these cases had previously been treated unsuccessfully by other methods. Forty-four patients were passing cysts, and 20, cysts and EHs prior to treatment. Of the 44 cyst-carriers, 31 (70.4 per cent) became negative after one course; 2 (4.5 per cent) required two courses, and 11 (25 per cent) showed in their stool after the first course not only cysts but also EHs. These 11 cases received a second course and at the end of the second course only 2 patients were still passing cysts. So that after two courses the treatment was successful in 42 (95.5 per cent) cases of cyst-carriers and failed in 2 (4.5 per cent). Amongst those patients who had become negative there were 3 cases of relapse after 1, 4 and 8 months respectively. However, it is difficult to say whether these cases were real relapses or fresh infections.

Twenty patients had on first examination EHs and cysts, and were treated with retention enemas. Of these cases, 5 (25 per cent) were cured after one course, 13 (65 per cent) were cured after two courses, and 2 (10 per cent) were still passing cysts after two courses. If the 11 cases of the first group who were passing EHs after the first course are added to those with amœbæ, then there are 4 (12.9 per cent) out of 31 patients with amœbæ who were not cured after two courses. Sixty-four cases of amœbiasis were treated with E.B.I. retention enemas. Four cases (6.3 per cent) did not respond to the treatment. Three patients (4.6 per cent) had a

relapse. All these cases had their stools examined for at least 2 months, and have been under observation for over 10 months.

This method of treatment has none of the unpleasant effects of E.B.I. when given by mouth. In the majority of the cases it causes neither discomfort nor pain. During the first 3 or 4 days there is, though not as a rule, an increased elimination of mucus and in a very few cases even of blood with the stools. These cases had also 3 to 5 motions daily. The mucus and the occasional blood in the stool might be regarded as a worsening of the condition, but it could also be viewed as a 'flare-up' of a chronic process. This would be useful for the treatment, because an acute process is less difficult to treat than a chronic one. I have the impression that due to the action of the enema the superficial epithelial layer of the intestinal mucosa may have been removed, and thus deeper-seated nests of the amœbæ may have been laid bare and brought to the surface of the intestinal lumen. This seems indicated by the number of cyst-carriers who after the first course passed not only cysts but also EHs with their stool. Except a few very resistant cases, all these patients were cured after the second course of E.B.I. retention enemas.

The treatment described in this paper has the following advantages:—

1. It can be given in the surgery or out-patient department.
2. It does not require any rest in bed or hospitalization if the latter should not be necessitated by the general state of health of the affected.
3. It causes little or no discomfort, and while undergoing treatment, the patient can attend to his work and fulfil his duties.
4. It is very economical as it requires a minimum amount of rather inexpensive drugs.

Summary and conclusions

Amœbiasis is an infection which is localized mainly in the colon and in the rectum. Therefore, local treatment by topical application of medicines is indicated. Treatment by means of small retention enemas containing E.B.I. is suggested. The results of 64 cases treated with this method are reported.

SEROLOGICAL TECHNIQUE (contd.)

By S. D. S. GREVAL

LIEUTENANT-COLONEL, late I.M.S.

(From the Laboratory of the Imperial Serologist and Chemical Examiner to the Government of India, School of Tropical Medicine, Calcutta)

The Serum

The unknown serum.—Colour, turbidity, presence or absence of particles and state of preservation are noted. As much as possible is transferred to a sterile phial capable of holding 10 c.c. The phial is corked and on the top of

the cork is written in ink name, number or other distinguishing mark of the patient. The corked phial is inverted into melted paraffin well beyond the mouth of the phial. The paraffin seals the corked phial, prevents evaporation, makes the cork firm and preserves the writing. The sealed phials are put on a tray and immersed up to the neck in a water bath at 55 to 56°C. for half an hour for inactivation of the natural complement.

After inactivation the phials are arranged along a rack holding empty sterile test-tubes for dilution. The tubes are written upon with a glass marking pencil (yellow recommended) in accordance with the bottles. 2 c.c. of saline are put into all tubes. With sterile 1 c.c. graduated pipettes 0.5 c.c. of serum is transferred from each phial to its tube. The serum is now diluted 1 in 5. If a serum becomes turbid on dilution T is put on the dilution tube in blue pencil. For sera that are opalescent before dilution Op is put on the dilution tube. The pipettes are left in the tubes. The phials are recorked and stored in the cold.

From the dilution tubes 0.25 c.c. of the 1 in 5 sera is distributed into a column of 5 tubes. On all the tubes of the column are written the name, etc., with a glass marking pencil and the colour of the diluted serum (Op = opalescent serum; T = serum turning turbid on dilution; B = brown; R = red; P = pink; Y = yellow; C = colour nondescript). Opalescent sera and sera turning turbid may give false reactions due to their unstable colloid state. Yellow sera may also give a false positive reaction due to jaundice (and liver disease). The colour may appear like a trace of hæmolysis (T) in a positive reaction. The colour noted at this stage is going to decrease on the addition of 3 more volumes of fluid to the tube. For this reason the marked tubes are inspected again immediately before adding the rbc suspension. Any colour still present needs a special colour control: serum dilution 1 vol. + antigen 1 vol. + saline 1 vol. + rbc suspension 1 vol., to be incubated and treated like other tubes.

The serum is put in the tubes at this stage although it is shown as a part of the change in the full plan, later.

The known negative serum.—When the number of the unknown sera to be tested exceeds 24 or so this control is not necessary. Negative sera will stand out as such.

The known positive serum.—Serum pooled from about 25 cases of untreated florid secondary syphilis, diluted 1 in 10 with 2.5 per cent phenolized saline for preservation and filtered through Seitz filter gives full and partial fixation of complement on further dilution. After standing in the cold for about a month the titre of the reaction falls but remains constant for months (until the stock is exhausted). The following is a typical reaction with antigen 1 or antigen 3.

The 1 in 50 and 1 in 100 dilutions of the serum giving constant reactions are the *titrated*

	REACTION WITH	
	3 MHD of complement	5 MHD of complement
(1) Freshly pooled serum :		
1 in 50 ..	+	+
1 in 100 ..	+	+/-
1 in 200 ..	T/±	±/-
(2) After a month :		
1 in 50 ..	+	+/-
1 in 100 ..	T	T/±
1 in 200 ..	±/-	-

positive controls. Their margin of variation is small. The end point of complete fixation is indicated either with 3 or 5 MHD. When it is just indicated with 3 MHD the fixation is optimal. When it is plainly indicated with 3 MHD it is rather on the low side. When it is indicated with 5 MHD only the fixation is rather on the high side. When it is not indicated at all the fixation is too high: all negative reactions in the test will be accepted but all doubtful (T/±) and positive (+) reactions will be repeated. Conversely, when full fixation is not found even with 3 MHD the fixation is too low: all positive reactions will be accepted but all doubtful and negative reactions will be repeated.

The author pointed out many years ago that without the titrated controls the daily variations in the complement fixation were large enough to invalidate all ± and some + or - reactions. The ordinary positive control obtained from serum tested yesterday is not indicative at all of the reactions to-day, for the simple reason that it is being put up in a 1 in 5 dilution, while it may be positive in a 1 in 200 dilution.

The various adjustments in the antigen-complement system have been worked out with the aid of the titrated positive controls in the author's laboratory. They have stood the test of time.

Charging of tubes for serum.—For each serum 5 tubes are used in a column and charged as follows:—

A column.

For a serum dilution, 1 in 5, 1 vol. in all tubes (see sketch on page 385. There is a column for every serum under test in addition to 2 columns for the titrated controls).

5th row tube.	{ Complement in 1 vol. of dilution, 4 MHD (for + + +, standard) Antigen 2.
4th row tube.	{ Complement in 1 vol. of dilution, 5 MHD (for + +, standard) Antigen 1 or 3.
3rd row tube.	{ Complement in 1 vol. of dilution, 3 MHD (for +, standard) Antigen 1 or 3.

2nd row tube.	{ Complement in 1 vol. of dilution, 2 MHD (for +, additional) Antigen 4.
1st row tube.	{ Complement in 1 vol. of dilution, 2 MHD (for serum control) Saline 1 vol. (no antigen).

Antigen and complement are mixed and delivered as a double volume.

Left at room temperature $\frac{1}{2}$ hour and in the incubator at 37°C. for $\frac{1}{2}$ hour.

Sensitized rbc suspension 1 vol. added to all tubes.

Incubated $\frac{1}{2}$ hour.

A column for titrated controls for serum.

Dilution 1 in 50 or 1 in 100, 1 vol. in all tubes. (Two such columns, one for each dilution, are put up.)

4th row tube { Complement 5 MHD Antigen 1 or 3

3rd row tube { Complement 3 MHD Antigen 1 or 3

2nd row tube { Complement 2 MHD Antigen 4

1st row tube { Complement 2 MHD Saline (no antigen)

The serum control 1 in 50 should not be anti-complementary.

Typically the reactions should be :—

1 in 50 serum.	{ +/± with antigen 4 and 2 MHD. Usually ± with old fluid. 1 or 3 and 3 MHD. 1 or 3 and 5 MHD.
1 in 100 serum.	{ ±/- with antigen 4 and 2 MHD. 1 or 3 and 3 MHD. 1 or 3 and 5 MHD.

Controls of other reagents.—One set of controls for all other reagents used on the day of work is also prepared as shown below :—

A. For sensitized rbc.

Suspension 1 vol. + saline 3 vol.

B. For complement.

Comp. 1 MHD + saline 2 vol.

C. For antigen no. 1 or 3.

Comp. 2 MHD + ant. 1 vol. + saline 1 vol.

D. For antigen no. 4.

Comp. 1 MHD + ant. 1 vol. + saline 1 vol.

A is kept in the cold until the others have been incubated like the test and the sensitized rbc suspension has been added to them. Finally all are incubated and treated like the test.

Examination of the controls.—This is undertaken before the results of the test are read and in this order: (1) The sensitized rbc control. It should not show even a trace of hæmolysis. (2) The complement controls. The MHD of complement alone and in the presence of antigens should not show any appreciable deterioration. The hæmolysis should be complete in B, C and D. (3) The titrated controls. The serum dilution should not be anticomplementary. 1 in 50 dilution should fix 3 MHD completely. 1 in 100 dilution should not fix 5 MHD completely.

Reading of results for serum.—1. Immediately.

- A. Almost crystal clear and ruby red tubes = —
- B. Tubes falling short of A = ? — Provisional.
- C. Tubes only partly hæmolysed, obviously coloured supernatant fluid on an obvious and red deposit = ±
- D. Tubes apparently not hæmolysed at all = + Provisional.

In B it should be noted if all the tubes other than the serum controls are equally hazy. Some sera produce such equal haziness with the antigen without interfering with the hæmolysis. They are read as Ant(igen) Turb(idity) provisionally.

The racks are transferred to the ice chest for the night for the correct appraisal of B and D.

2. Next morning.

- B. Showing no deposit with a lens or the merest trace of colourless deposit = —
- B. " coloured deposit with a lens = ? —
- D. " no trace of hæmolysis = +
- D. " trace of hæmolysis = T
- D. " considerable hæmolysis = ±

Record and report for serum.—For the record the tubes are again treated as if running in a row from left to right (see TABLE OF WR RESULTS).

A marked difference between reactions of antigens

In the last two reactions of the table, XX and XXI, the doubtful or positive reaction is looked upon with suspicion and a search made for a non-specific cause (*vide infra*). A repetition of the test may be necessary.

It will be observed that a difference of the opposite kind has been ignored in reaction XVIII and just recognized in reaction XVII.

Explanation concerning anticomplementary sera

Certain sera like certain antigens render complement inert. They are anticomplementary. They usually acquire this property on keeping, but some sera are anticomplementary to begin with. A low anticomplementary titre of a serum can be made to disappear by heating at 55 to 56°C. for half an hour. This is accomplished at the time when the serum is inactivated.

Generally fresh normal human serum is not anticomplementary but *procomplementary* or neutral in its reaction with the complement.

When a serum has been found to be anticomplementary and another specimen is asked for, it is presumed that the original specimen had become anticomplementary on keeping.

It is not always possible to report on an anticomplementary serum. Sach's process of removing the anticomplementary substance may be tried (Process: Add 8.2 vols. of N/300 hydrochloric acid to 1 vol. of heated serum, leave $\frac{1}{2}$ hour and centrifuge to remove precipitate. Neutralization is not necessary as the acid is fixed in the precipitate of globulin.

TABLE OF WR RESULTS

	Tubes of row :—					Result (Tube in row 2 does not count if corroborative).	Report
	1	2	3	4	5		
I	—	—	—	—	—	—	Negative.
II	+	+	+	+	+	Ant. comp. Repeated 1 in 10 for III and IV.	Nil. May react as in 1 in 10.
III	±	±	±	—	—	—	Negative.
IV	T	+	+	+	+ / T	+	Positive. Degree not known. May be repeated in 1 in 10.
V	T	+	+	+ / T / ±	—	Ant. comp.	Anticomplementary. Repeat specimen.
VI	—	+	+	+	+	+++	Positive, strongly.
VII	—	+	+	+	T	++T	
VIII	—	+	+	+	—	++	Positive.
IX	—	+	+	T	—	+T	
X	—	+	+	±	—	+±	Positive, weakly.
XI	—	+	+	—	—	+	
XII	—	+ / T	T	T	—	TT	Doubtful. These reactions are not 9/10-5/10 positive.
XIII	—	+ / T / ±	T	±	—	T±	
XIV	—	+ / T / ±	±	±	—	±	
XV	—	+ / T / ±	±	—	—	±	Doubtful. Repeated before reporting.
XVI	—	T / ±	? —	—	—	±	
XVII	—	+	—	—	—	±	Doubtful: (i) significant with history, (ii) not significant without history.
XVIII	—	T / ±	—	—	—	—	
XIX	—	—	—	—	—	—	Negative.
XX	—	—	T / ±	±	—	±	Doubtful.
XXI	—	—	+	+ / ± / —	—	+	Positive or positive, weakly. Repeated before reporting. TT is the usual highest reading in tubes 3 and 4 when tube 2 is —.
XXII	—	—	? —	—	—	—	Negative.

Add 0.8 vol. saline to obtain a 1 in 10 dilution of the serum).

In combination III as long as all ± hæmolyses (or inhibition of hæmolysis) are of the same order there is no danger of missing a doubtful reaction.

Anticomplementary titre is reduced more rapidly than the positive titre, on dilution. When a typical positive reaction is obtained with a 1 in 10 dilution of the serum the positive titre is really higher than the one recorded.

Explanation concerning planning of symbols in records

Should 3 consecutive records or 3 different grades of positiveness be written, in columns

as +++ or +++
 ++ ++
 + +

As the tubes are charged for giving rising reactions from left to right and are read from left to right, the record should also be from left to right, unlike an arithmetical sum.

It will be observed that although there are 22 different combinations for record the report only gives 6 findings: (1) positive, strongly, (2) positive, (3) positive, weakly, (4) positive, degree unknown, (5) doubtful, (6) negative. From the records, however, the repeated reaction of a patient's serum under or after treatment, or with the mere passage of time, can be easily compared.

A MEDICAL MISADVENTURE—DEATH FROM STERNAL PUNCTURE

By P. N. BARDHAN, L.M.S. (Singapore),
F.R.C.P. (Edin.), D.P.H. (Edg.), D.R.C.O.G., M.M.S.A.
LIEUTENANT-COLONEL, I.A.M.C.

Adviser in Pathology, Southern Command

Introduction

DEATH from any cause is regrettable, and that from a preventable one more so. That a simple procedure like sternal puncture may be attended with fatality is very disturbing and calls for a full analysis when this occurs. This paper describes two cases in whom this happened and also suggests an explanation of the mechanism involved in causing the deaths.

Case records

The first case occurred at a military hospital in 1945. On a preliminary examination a diagnosis of kala-azar was made, and as the spleen was only slightly enlarged, it was decided to perform a sternal puncture to confirm the diagnosis. The doctor attempting the puncture was experienced in the procedure, and he was a competent general physician conversant with the problems involved. After novocain infiltration of the soft tissues and the periosteum, a Bole Brothers make of sternal puncture needle was suitably guarded to expose 8 mm. of the pricking end. It may be mentioned here that this needle is guarded by a screw-guard which cannot slip. It was considered at the time, and proved afterwards at autopsy, that the needle as guarded could not pierce the posterior plate of the sternum, under ordinary circumstances; the guard being of the type that cannot slip, the needle could not go beyond the pre-determined length. And yet when the needle was pushed in, there was a gasp from the patient who rapidly became shocked, and died within three minutes. Anti-shock measures were adopted without avail though it was not realized at the time that death had occurred from anything but a severe sudden shock; the clinical picture resembled that of pulmonary embolism with which many are familiar.

At autopsy it was found that the posterior plate of sternum had the minutest puncture through which the tip of the needle could just be protruded. Opposite this puncture hole, there was a laceration $\frac{3}{4}$ inch long in the anterior wall of the right ventricle. There was hæmopericardium and death had occurred from pressure on the heart, preventing further action of the organ. With the cadaver lying supine, the end of the needle introduced through the original route could not be made to touch the heart. The autopsy was performed within an hour of death. The other relevant findings were those of an early stage of kala-azar, the parasite being seen in smears taken from the spleen and the serum giving a positive reaction to Chopra's antimony test. Death was decided

to have been due to a traumatic rupture of the heart from the sternal puncture, though a certain amount of uneasiness was felt in view of the fact that it was assumed that the needle could not have touched the heart.

The second case died under similar circumstances in a civil hospital in 1946. The order of events was approximately the same as in the first case. The needle was guarded by a plate and there was a possibility that the guard had slipped. But this was in fact not so; the guard was placed so as to expose 11 mm. of the needle and this was a safe length for the particular patient as considered at the time and also as confirmed at autopsy. The operation was performed by a competent surgeon who, however, had not performed this operation before. Novocain infiltration was used and no sooner had the needle been pushed into the sternum than the patient gasped and became shocked. Death took place in not less than two minutes, perhaps after four minutes. The surgeon had an opportunity of discussing the first case some time ago, and rupture of the heart was at once thought of. The autopsy revealed a laceration $\frac{7}{8}$ inch long in the right ventricle and a hæmopericardium. The other findings were normal except for an aortic incompetence. The operation had been undertaken to study the bone-marrow for anæmia.

In both cases the laceration was larger on the pericardial aspect than on the endocardial, and the measurements are of the pericardial aspect.

Discussion

That two deaths should have occurred in the course of a rather simple surgical procedure and the absence of a satisfactory explanation for these was rather tantalizing. The matter was discussed with several people who were used to the procedure and the best criticism that could be offered was that there was an error in fixing the guards; but this was in fact not so. Even if it was, the happenings would not have been fully explained, for it is known that a puncture of a muscular organ is easily sealed off immediately after the needle is removed; intracardiac injections are not attended with hæmorrhage into the pericardial sac.

A review of the cases made several facts stand out. Firstly, the needle had punctured the posterior plate of the sternum, though to a very minute degree only, in each case. Secondly, as no premedication was used, the patients were rather apprehensive and probably held their breath. Thirdly, death was in each case due to arrest of the heart from continued hæmorrhage into the pericardial sac. Fourthly, the laceration involved the right ventricle and was nearly an inch long. Fifthly, the needle could not have touched the heart under ordinary circumstances. Sixthly and finally, there was no other cause of death found.

The heart is a very muscular organ, constantly stretching and contracting in diastole and systole respectively. That the tension in the heart is increased by holding the breath is an accepted fact of physiology. Holding of the breath causes an increased carbon-dioxide tension in the venous blood and this increased CO_2 tension enhances the extensibility of the cardiac muscle fibre during diastole. A person can by holding his breath, therefore, make his heart a little larger than normal, and a larger heart will tend to come nearer the sternum. This heart will be more stretched than normal. It is easy to visualize how an apprehensive person will, by holding his breath, bring the heart nearer to the posterior surface of the sternum and thus make it more susceptible to possible trauma from even a minute portion of the sternal puncture needle. It is also easy to see that while a contracted heart may throw off a needle, a relaxed heart may not be able to do so; in fact in a relaxed muscle a small prick will be rapidly converted into a tear if behind the relaxed muscle there is some other force. In diastole of the heart while the muscle is relaxed, there is a constantly rising pressure within the heart. Here then were the circumstances that could explain the two deaths. The apprehensive patient holds his breath, renders the heart slightly larger in size and more extensible, brings it nearer the sternum, where it is touched off by the small unsuspected portion of the needle, the rising tension of the heart converts the minute puncture into a laceration, and hæmopericardium follows.

A series of experiments was then conducted by dropping sharp needles weighted near their business ends on to football bladders which were put under varying degrees of tension. A high tension threw off the needles; a very relaxed bladder did not offer the needle any foothold though a mark was sometimes made. A medium pressure was found to be optimal for production of a puncture. If the bladder was kept attached to the pump, and the needle was dropped when the bladder was about two-thirds stretched, a puncture was easily produced, and the pressure of the pump overcoming the elasticity of the bladder, the puncture was made into a rent. Though suggestive, the experiments did not conclusively prove anything, for the same needle similarly weighted and dropped on the bladder under the same optimal tension did not always produce the tear. It was considered necessary to discover some more cogent explanation which, by itself or in conjunction with what has been said above, would explain all the phenomena.

It has been seen that in performing a sternal puncture, the needle is often pushed in by a series of jerky movements rather than by a steady pressure. These jerky movements give rise to two other movements. Firstly, with each jerk, the sternum tends to flatten out and come in

closer contact with the heart, and secondly with each jerk the patient becomes more apprehensive, causing the man to hold his breath and thus setting in motion the mechanism described above whereby the heart is rendered more liable to trauma from the sternal puncture needle. The jerks also damage the soft tissues in front of the sternum and reduce their depth, and allow the needle to go a trifle deeper. There is, thus, an unintentional and unsuspected increase in the range of the needle.

If heavy pressure is used in forcing the needle through the cortical layer of the sternum, there will be further sterno-cardiac approximation. One jerk may not puncture the heart, for the heart may be contracted in systole, but the next very well may, when the heart may be in diastole and by force of circumstances detailed above held pressed behind the sternum with the wall relaxed but the intracardiac pressure rising.

Experiments were then made on cadavers. It was seen that with the force of the jerky movements associated with sternal puncture, the sternum could be pressed down for nearly an inch and the soft tissues could be reduced in depth for up to 4 mm. If the anterior mediastinum which is after all only a potential space is fully obliterated by the heart, and there is an unsuspected increase in the range of the needle, there is nothing to prevent a traumatic rupture of the heart.

There can be little doubt that the two deaths occurred in the above manner, the sequence of events being as follows:—

1. Apprehension caused holding of the breath and this in turn led to stretching of the heart and its approximation to the sternum.
2. Jerky movements caused an unsuspected increase in the range of the needle; they also caused more approximation of the heart to the sternum.
3. The needle, then, unsuspectingly pierced the posterior plate of the sternum and caused a small prick in the apposed heart.
4. The heart having been put on the maximal stretch both by diastole and increased CO_2 tension, the prick rapidly became converted into a laceration by the rising intracardiac pressure.
5. Hæmopericardium followed leading to mechanical arrest of the heart, and to death.

Conclusion

It will be seen that a whole set of conditions has to be fulfilled before the catastrophe can occur in the above manner. It is not unlikely that this does not happen so very often, and may explain why there are so few deaths in attempting this operation. This, if true, is indeed a fortunate coincidence seeing how very casually sternal puncture is generally under-

taken. The lessons taught, in any case, should not be ignored. They are :—

1. Apprehension in the patient should be forestalled by suitable premedication.
2. The adjustment of the needle should be checked just before the operation. In doubt it should be guarded too much rather than too little.
3. Only the minimum amount of force should be applied and that in a steady pressure, and not in jerks; in fact, great gentleness should be used.
4. The anatomy of the regions affected should be visualized before the operation, and the dangerous nature of this apparently simple procedure remembered.
5. The routine for performing the operation should be standardized and converted into a ritual, as other pre-operative measures have been. The adherence to a strictly followed routine renders mistakes easy of detection.

Summary

1. Two cases are described in which death occurred after sternal puncture.
2. Death was in both cases due to a rupture of the right ventricle following a prick by the needle, causing hæmopericardium and arrest of the heart.
3. The possible mechanism leading to the rupture is discussed and results of certain experiments made in this connection are mentioned.
4. Certain precautions are suggested to prevent such catastrophes.

Note.—The production of a laceration of the heart by the contracting heart itself rubbing against a protruding needle presupposes too much penetration by the needle, and is to be explained by carelessness, and does not form part of this paper, which merely tries to point out some hitherto unrecognized dangers of sternal puncture.

Thanks are due to Dr. S. Nagaswami, M.B., B.T.M., for records of the first case, to Major W. Merrivale, R.A.M.C., M.R.C.P., Specialist in Pathology, for the autopsy report of the same case and also for allowing conduction of certain experiments in his laboratory, and to Lopamudra Bardhan for help with preparation of the paper.

ARTHRODESIS OF SHOULDER

A CASE REPORT

By ASITA LAL SOM, M.B., F.R.C.S. (Edin.)
Teacher of Clinical Surgery, Campbell Medical School

ARTHRODESIS of the shoulder from above has been performed for many years, with parts of the acromion process and the clavicle as grafts attached to the upper end of humerus. This technique ignored the fact that the shoulder tends to adduct through gravity and slight adduction may separate the graft with chances of failure of fusion. Brittain recently pointed out that it is not enough that the graft should have an adequate bed and that it is well secured but that the graft should be placed with its long

axis in compression rather than in tension. He applied the architectural principle of a lamp hanging from a wall by a bracket and supported by a stay. If the stay is an underlying one it is in compression and consequently the two ends of the stay tend to become secure, whereas if the stay is an overlying one, there is tendency of separation of the two ends of the stay due to gravity [vide figure 1 (a) and (b)].

Fig. 1.—(a) Showing position of the stay under tension. Lamp hanging from a wall by a bracket and supported by an overlying stay. The stay is in tension, and there is tendency to disruption at points A and B. (After Brittain.)

Fig. 1.—(b) Showing the position of the stay in compression. An ideal position for the bone graft. Lamp hanging from a wall by a bracket and supported by an underlying stay. The stay is in compression. Consequently points A and B are tending to become more secure. (After Brittain.)

In other words if the graft is placed below the scapulo-humeral joint, there is every possibility of the graft taking, thus leading to a sound arthrodesis.

The following case will illustrate the result of such a technique.

Case record

Ramu, driver, aged 24, Hindu male, met with a lorry accident on 5th January, 1946, and sustained fracture dislocation of right shoulder joint. On 15th February, 1946, the deltoid was found markedly wasted and flaccid with prominence of the bony landmarks. Head of the humerus could be felt in the axilla and there was a small area of sensory loss over the outer side of arm. Marked limitation of shoulder joint, especially abduction. X-ray showed the fracture line through the anatomical neck of the humerus and the head lying below the glenoid cavity.

On 20th June, 1946, extra-articular arthrodesis of shoulder joint was performed with a graft taken from tibia (*vide* figure 2, plate XVI). The shoulder was approached from the posterior aspect and a massive tibial graft was inserted into the humerus and the axillary border of the scapula below the shoulder joint.

The graft was cut with an osteotome and Brittain's technique was followed. The result is very gratifying as may be seen from the photographs [*vide* figure 3 (a), (b), (c), (d) and (e), plate XVI].

Comment

When the case was first seen by the author it was more than five weeks old. At that time traction and manipulation would probably have failed to reduce the dislocation. Open reduction was thought of, but one doubted its result because of the possibility of avascular necrosis of head and further operative procedure disturbing the remaining vascular supply of the head. Moreover, the patient had right axillary nerve palsy. Arthrodesis was considered as the proper line of treatment at that stage. This judgment was also based on considerations of the occupation and the age of the patient.

My thanks to Major E. H. Lossing, M.D., I.M.S., for allowing me to report this case which was also demonstrated in a clinical meeting at the School of Tropical Medicine, Calcutta.

TREATMENT OF MAJOR BURNS IN 1940 AND 1946

COMPARISON OF TANNIC ACID TREATMENT WITH COMPRESSION BANDAGE METHOD

By M. MUKHERJEE

Resident Surgeon, Campbell Hospital, Calcutta

AN attempt is made in this article to compare the results of general and local treatment of

major (Wallace, 1941) burns in the above-mentioned years. By major burn is meant any burn that covers more than 1 per cent of the body surface or that covers any joint surface or that is too near any source of natural contamination, e.g. mouth, anus, etc. In 1940, shock was treated by ordinary normal saline or gum saline and the burnt areas were tanned by tannic acid in 1 in 1,000 acriflavine. In 1946, one had the good fortune of treating shock with serum and the burnt areas by compression dressing using sulfathiazole and vaseline gauze. The infections could be prevented or combated by penicillin in 1946 over and above the sulfa group of drugs of 1940 and of later years.

If one traces the history of local treatment of burnt areas, one comes across a great many ointments and tanning reagents. Starting from picric acid, cod-liver oil, one passes through 1925 when Davidson (Lee and Rhoads, 1944) introduced tannic acid to precipitate the denatured protein and thus to prevent absorption of burn-toxin as that was the accepted theory at the time. He claimed that tannic acid stopped fluid loss too. Tannic acid held the field in treatment of burns for nearly 20 years. Tannic acid brought the mortality rate down from 26.7 to 10.5 per cent in Harkins (Riehl, 1942) series of cases. The tannic acid treatment has been losing its reputation rather quickly. It has been suggested by Erb, Morgan and Farmer (1943) that tannic acid causes liver damage after absorption from the burnt area especially when a big surface is involved. Tannic acid is also toxic to epithelial cells. Pus spreads under the crust spreading infection from 3rd degree areas to 2nd degree areas. Mild infections under the crust destroy a number of epithelial islets especially in deeper 2nd degree burns. The crust is uncomfortable to the patient and takes a long time to separate. In 3rd degree burns which are almost always infected, the crust with the pus underneath it will only delay healing processes (McIndoe, 1940).

The method of surgical cleanliness, compression bandage using some antiseptic ointment and rest, is advocated by many in America (Koch, 1944). A simple method of the above principle was followed in the series of cases treated in 1946 in the Campbell Hospital and is described below in detail.

Procedure.—As soon as a burn case came to the out-patient department, the officer on duty quickly examined the case. To a case of major burn, he gave a proper dose of morphia, covered him up with a clean sheet and blanket and sent him to the in-door ward. In the wards the dirty clothes were taken off and the patient was put on a sterile sheet. A sterile sheet covered him and then the blankets, electric cradle, etc., were used according to the necessity. In the cases with less than 10 per cent of the body surface burnt, the electric cradle was not needed except in winter. Then the patient was treated for shock

with serum or saline when serum was not available. (In this respect one is sorry to remark about the scarcity of serum since the war has stopped, most probably due to decreased number of donors visiting blood banks these days.) Adrenal cortex was used in some severe cases without any convincing result.

As soon as the patient recovered from shock or if he had a mild shock, attention was paid to the local treatment. In the earlier part of the series, general anaesthesia used specially in patients who recovered from moderate or severe shock proved definitely harmful. Two cases with less than 20 per cent burns died of shock within a few hours after cleaning was done under general anaesthesia (open ether was used) though they recovered from shock before the operation. So in the latter part of the series general anaesthesia was not used in such cases. Cases with less than 10 per cent area burnt did not affect the result whether general anaesthesia was used or not. Still in most cases attempt was made to tackle the case without anaesthesia and with administration of morphia only.

Cleaning.—Cleaning was done in the operation theatre with rigid aseptic technique, i.e. with masks on, etc. The blisters were snipped off. The parts were washed with sterile normal saline and cotton-wool swabs. Utmost gentleness was practised in the matter of washing; no rubbing but only dabbing was done, the note of warning being complaints of pain by the patient. In fact if this procedure is carried out carefully and gently, the patients are not disturbed from the soothing effects of a proper dose of morphia ($\frac{1}{4}$ to $\frac{1}{2}$ gr. for adult). Sulfathiazole powder was sprinkled uniformly over the cleaned areas with a gauze puff containing the powder. Total amount of the powder to be used was restricted to 8 to 12 grammes and this was sufficient in all cases. Then two layers of wide-meshed vaseline gauze were placed over the parts. Six to eight layers of gauze and $\frac{1}{4}$ inch thick layer of cotton-wool were used to cover the parts. The bandage was applied fairly tightly except in cases of chest wall. In the limbs the bandage was applied from the ends if the burnt area was near the wrist or ankle. The parts were watched carefully so that the tightness might not reach the stage of occlusion of vascular supply. The parts were kept at rest using splints for the limbs, elevating the limbs whenever much swollen.

Treatment of shock was continued or repeated in bad cases as necessity arose. Systemic administration of sulfathiazole or penicillin was started as a routine from the 2nd day and continued for the first seven days or for three days after there was no fever. If in any case the temperature persisted after seven days, a gap of three days was given before starting the next course of sulfathiazole. Usually these cases were followed by penicillin with very encouraging results.

Systemic medication to combat infection in cases of burns with 10 to 30 p.c. of body area burnt

	Total number of cases	Number of cases who were cured	Number of cases who died of infection
Penicillin ..	11	10	1
Sulfathiazole ..	18	15	3

It is obvious from the above figures that penicillin was much more effective in preventing and curing infections of burnt areas. It should be the drug of choice in all cases.

The first dressing was changed after 7 to 10 days. In all cases of 1st degree and superficial second degree burns the wounds healed up within this period. Patients were discharged cured in 10 to 14 days. The areas that were not dry or epithelialized were treated again with sulfathiazoles and vaseline gauze kept for another week. Quite a number of cases healed up in another one or two dressings, i.e. within 21 days. The remaining cases needed a skin graft and the same was done as soon as the area showed healthy granulation tissue. Skin grafting was necessary in all 3rd degree burns. The 2nd degree burns never produced secondary degeneration of epithelial islets so as to require skin grafting. Skin grafting was possible much earlier in this series of cases than was possible in cases treated with tannic acid. Complications like broncho-pneumonia, pyæmia, septicæmia have nearly become unknown with this method of treatment. In 1946 series there was only one case of broncho-pneumonia amongst 91 cases, whereas in 1940 there were 5 cases in a series of 80. The following are the tables for comparative study in the two years with two different methods of treatment (see tables I and II).

It will be seen that the death rate in 1946 was nearly half of that in 1940 taking all cases. When the cases with more than half the body surface burnt are excluded, then the death rate in 1946 is almost a third of that in 1940. Of the four cases of death due to infection in 1946, penicillin could not be provided for 3 cases as it was out of stock and out of market at the time (March-April 1946). Only one case died of infection even when penicillin was given parenterally.

Death between 3 and 5 days due to so-called acute toxæmia of burns is getting unknown these days.

In table II the number of cases getting severe infection is more than double in 1940 as compared to those in 1946. In 1946 penicillin was used only in 12 serious cases of whom only 2 developed severe infection. One can hope that when penicillin will be used for all cases both locally and parenterally, severe infection of burnt areas will become a thing of the past.

As the incidence of infection was much more frequent in 1940, so the average stay was much longer and this is corroborated by actual calculation.

Average stay in 1940 = 24.2 days (59 patients staying for 1,431 days).

Average stay in 1946 = 13.7 days (77 patients staying for 1,056 days).

routine measure in cases with more than 10 per cent area burnt.

6. The simple procedure of compression dressing described in the article is recommended for all cases of burns.

In conclusion, I am thankful to Major E. H. Lossing, i.m.s., Superintendent, Campbell Medical School and Hospital, to the resident medical officers of the surgical

TABLE I
Mortality

Year	Total number of patients treated	Number of deaths due to shock, i.e. within 48 hours	Number of deaths due to infection	Percentage of deaths due to shock	Percentage of deaths due to infection	Total percentage of deaths
1940	80	11	10	13.5	12.5	26
1946	91	9	4	9.5	4.5	14

If burns of more than half of the body surface which have so far been held to be hopeless cases are left aside the statistics are as follows :—

1940	75	6	10	8.0	13.3	21.3
1946	85	3	4	3.6	4.8	8.4

TABLE II
Infection

Year	Total number of patients living after 48 hours	NO FEVER OR INFECTION		FEVER FOR A WEEK WITH LOW GRADE INFECTION CAUSING NO DELAY IN HEALING		HIGH FEVER WITH SEVERE INFECTION	
		Number	Percentage	Number	Percentage	Number	Percentage
1940	69	23	33.3	21	30.4	25	36.3
1946	82	52	63.4	18	21.9	12	14.7

Summary

1. In 1940, 80 burn cases were treated with saline for shock and tannic acid for local areas with a mortality rate of 13.5 per cent from shock and 12.5 per cent from infection.

2. In 1946, 91 burn cases were treated with serum for shock and compression dressing with sulfathiazole and vaseline gauze for local area with a mortality rate of 9.5 per cent from shock and 4.5 per cent from infection.

3. Excluding cases, with more than 50 per cent area burnt, the mortality rate (8.4 per cent) and the incidence of severe infection (14.7 per cent) in 1946 have been brought down to nearly one-third of those in 1940 (mortality rate 21.3 per cent, incidence of infection 36.3 per cent).

4. In 1946, average stay of a patient in hospital (13.7 days) is decreased to almost half of that in 1940 (24.2 days).

5. Penicillin is the best drug for combating infection to burn cases, only one case died of infection when penicillin was being given as

wards and to the Chief Registrar for their kind collaboration.

EXPERIENCES OF RIOT SURGERY

A REVIEW OF 50 CASES

By A. K. BASU, M.S. (Cal.), F.R.C.S. (Eng.)

Teacher of Surgery, Campbell Medical School, Calcutta

THIS paper is an attempt at evaluating the results of established methods of treatment and new techniques of management of some 50 casualties resulting from the recent communal riots in Calcutta.

The casualties could be divided into the following categories :—

1. Abdominal stabs and gunshot wounds 12.
2. Stab wounds of the thorax 15.
3. Stab wounds involving soft tissue only 13.
4. Gunshot wounds of the extremities including compound fractures 10.

Abdominal stabs and gunshot wounds

These take the pride of place not only because of their frequency in this riot but also because they need the greatest attention and have the highest mortality.

Every case of abdominal stab or gunshot wound requires exploration however trivial the superficial wound may appear to be. This fact is well recognized and requires no emphasis, were it not for the fact that the extremely minor nature of the parietal wound often deludes the surgeon.

Example.—A small boy was admitted with a stab wound in the left lumbar region just below the costal arch. The wound was minute, and the child was in good condition with a slow pulse rate. The abdomen was soft. There was little tenderness, there was no fluid in the peritoneal cavity and peristalsis was active. The child had passed clear urine. The child was watched for 24 hours. On the second day his condition worsened and he complained of pain and increased tenderness in the left renal angle. Laparotomy disclosed subcapsular hæmatoma of the spleen. Splenectomy was performed.

The site and direction of the stab wound is a good indication of the structures likely to have been injured. A good illustration of this was in the man who was struck obliquely in the right loin and sustained laceration of the right lobe of the liver, perforation of the pyloric end of the stomach, first part of the duodenum and the adjoining portion of the transverse colon.

Gunshot wounds of the abdomen, however, have precarious pathways and often-times surprise the most painstaking surgeon.

When to operate.—It is a mistake to operate on any case of stab wound of the abdomen until the patient has been well resuscitated. I have heard it being expressed that if you cannot operate on these cases within the first 3 hours, the prognosis is almost hopeless. I have also noted the opinion of surgeons who say that shock for some reasons is conspicuously absent in these cases in the first few hours (Som and Mukherjee,

1947). In my experience this is a dangerous teaching. I find that shock in these cases is most profound within the first 2 to 3 hours and that unless the patient is in a reasonable condition to withstand what may be a major operation, it is a mistake to operate on them straightaway. The exception of course is in those cases where hæmorrhage is suspected. My practice is to insist on a well-regimented course of resuscitation and not to operate on any case until the systolic pressure has risen up to 100 mm. and diastolic to 60 mm. Hg.

Incision.—Routine use of paramedian incision is to be deprecated. There is a good deal to be said for the use of oblique and transverse incisions in selected cases. Exposure is much improved. Manipulation is easier, the general peritoneal cavity can often be left undisturbed and closure of the abdomen is less difficult.

Example.—A man received a stab wound of the right flank, the direction being downwards and inwards. The abdomen was opened by a transverse muscle cutting incision. It revealed lacerated injury of the right lobe of the liver and hepatic flexure of colon. Repair was easy. Two points need be stressed (1) that the general exploration of the abdomen, if necessary, can be well accomplished by the incision, and (2) that the resulting scar is quite sound.

If the wound of entry is somewhere in the back posterior to the mid-axillary line, it is a good practice to attend to this first and afterwards turn the patient on his back and proceed with the abdominal exploration. The advantages of this procedure are that (1) it causes less shock and that (2) surgeons are otherwise liable to forget about posterior wounds at the end of an exhaustive abdominal operation.

Another sound procedure and one which occasionally saves much unnecessary work and time is to investigate all the abdominal structures carefully and make a survey of all the lesions first before commencing actual repair. Very often multiple lesions are present in nearby segments of the bowel and after a time-consuming repair of a perforation, the surgeon is faced with a non-viable nearby segment when both could be included in a single resection anastomosis. Similarly injuries to solid viscera sometimes escape notice when they are associated with hollow visceral injuries. My own practice is to examine the solid viscera first after opening the abdomen, to pack any sources of bleeding found and then to investigate the hollow viscera from stomach downwards and their mesenteries. If more than one lesion exist in the hollow viscera, I close them up temporarily with gauze cover held in place by Allis's forceps until they are taken in turn for repair. This avoids unnecessary spillage and also forms useful guide for the surgeon especially when he is in a hurry.

Dealing with the actual lesion: Small intestine.—It is generally recognized that repair

is always better than excision. Three facts need stressing :—

1. There is little danger of narrowing of the lumen and stenosis after repair. Even if the wound in the small gut involves two-thirds of the wall, repair is still to be preferred.

2. If there are two or more wounds in closely contiguous areas of small bowel, it may be feasible to join them and repair them together instead of separately (Turner, 1943).

3. Excision of the small intestine has a much higher mortality than repair.

The indications of excision of small intestine are :—

1. Crushing of the gut wall so as to make it non-viable.

2. Loss of blood supply due to considerable separation of the mesentery from the gut wall. In the present series of cases excision and anastomosis were necessary only in one case (2 per cent) and the man recovered.

Large intestine.—The advantage of exteriorization over repair and closure of the large gut lesions have been widely stressed in the last war. Over the mobile areas of the colon exteriorization is easy and less time-consuming. Over the fixed areas it may not always be possible and in such cases repair should be accompanied by local drainage and proximal colostomy.

The indications of excision in large gut lesions are practically the same as those in small intestine except that as the large gut stands exteriorization well, the need for excision arises less frequently. When it does arise however, immediate suture and anastomosis are to be deprecated as mortality from this procedure is high. The operation described by Paul Miculicz under such circumstances is a safer plan to follow.

Thoracic stab wounds

All cases of thoracic stab wounds treated during the riots have recovered. This is quite remarkable when contrasted with gunshot wounds of thorax (which were unaccountably absent in this series) in which mortality is said to be quite high. All these thoracic stab wounds were associated with extensive surgical emphysema and hæmothorax to a greater or lesser extent. Surgical shock was not a major factor, in fact its absence to any marked extent was remarkable. Only one case with open pneumothorax required resuscitation and he quickly recovered after the pneumothorax was closed. All cases of hæmothorax were aspirated as a routine, some requiring 2 to 3 aspirations. Average amount of blood aspirated was about 15 oz. Intrapleural instillation of penicillin was done at the time followed by routine parenteral penicillin.

I consider that routine use of intrapleural penicillin is a great advance in the treatment of thoracic injuries and explains much of the good results obtained.

Stab wounds involving soft tissues

These have been treated on orthodox lines and have not caused much difficulty. Primary excision or débridement followed by sulfanilamide dusting has been the usual method. I have preferred to leave the wounds open except in special areas such as the hand or the face. One remarkable case in which the right hand was literally bisected into two by a cut through the whole thickness of the palm between the middle and ring fingers and reaching up to the thenar and hypothenar muscles but somehow sparing the tendons and nerves made a perfect recovery with primary healing.

There was one case of nerve injury involving the ulnar nerve about the middle of the forearm, which was sutured about three weeks after the injury together with anterior transposition.

There were also a few cases of tendon injury involving the flexors and extensors of the fingers which were treated by secondary suture.

Gunshot wounds of the extremities including compound fractures

These have been treated on conservative lines, care being taken in the primary excision to save as many pieces of loose bones as possible. I have preferred skeletal traction to immediate plastering especially in the case of the femur. One case is worth recording. This was a man who had been shot at close quarters and had sustained an extensive lacerated wound in his right arm involving an area of five inches long with compound comminuted fracture of the humerus. The fractured area in the humerus involved its middle $\frac{1}{3}$ and there were many loose pieces of bones. There was also complete avulsion of the musculospiral nerve. Kirschner wire traction through the olecranon after primary excision of the wound caused rapid healing of the wound and after one month the arm was put in plaster according to Böhler's method. As it was impossible to suture the musculospiral nerve, tendon transplantation using the flexor tendons of the forearm was performed after six weeks and the man now has a remarkably efficient limb with a soundly united humerus and 80 per cent power of extension of the wrist joint restored.

Summary

1. This paper is based on the experiences of the recent riot casualties in Calcutta.

2. A few salient points in the management of abdominal stab and gunshot wounds have been mentioned.

3. Thoracic stab wounds have been remarkable for the absence of marked surgical shock and for rapid recovery. Routine use of penicillin is responsible for the latter.

4. Soft tissue injuries and gunshot wounds of extremities have been treated on usual lines. Skeletal traction is preferred to plaster fixation in the treatment of compound fractures.

TRAUMATIC ARTERIAL SPASM

By G. AHMED

LIEUTENANT-COLONEL

Professor of Clinical Surgery, Lake Medical College,
Calcutta

Introduction

THAT the arteries undergo spasmodic contraction, when subjected to trauma or concussion violence, is now a well-recognized fact. Called by the French surgeons 'Stupeur Arterialle' and by the German surgeons 'Kroh's Arterial Spasm', the phenomenon was described by Makins (1919) towards the end of World War I. During World War II, several remarkable instances of the condition were cited from diverse theatres of war.

In a series of 567 cases of battle casualties treated in an Indian general hospital, the phenomenon was observed in twenty-seven cases or roughly in 5 per cent of the cases. Actual incidence may be higher as by the time these casualties arrived at the hospital, some of the milder forms of the arterial spasm had already subsided.

Blood vessels in which the phenomenon was noted

Axillary artery	3
Brachial artery	8
External iliac artery	1
Femoral artery	4
Popliteal artery	5
Posterior tibial artery	6
TOTAL			27

Causative factors

Gunshot wounds	15
Shell wounds	4
Bomb wounds	4
Non-missile compound fractures	2
Application of tourniquets	2
TOTAL			27

Description of the phenomenon in the present series of cases

The affected segment of the artery, together with a portion above and below it, was usually found to be empty and firmly contracted. In extreme cases, the reduction in the calibre reached as much as one-sixth of the normal circumference. The branches or collaterals arising from the affected part shared the same fate. The radial or the posterior tibial pulsation was

obliterated. The hand or the foot was pale and cold.

This phenomenon of segmentary contraction was noted more frequently in the brachial than in the axillary, more in the femoral than in the external iliac and more in the posterior tibial than in the popliteal, as will be evident from the incidences in the respective vessels as stated above. In other words, the medium and small-sized vessels of the extremities were more often affected than the large vessels at the roots of extremities. Rene Leriche observed the same incidence.

In one case of gunshot wound through the right arm, two inches above the bend of the elbow, the brachial artery was perforated. But there was no extravasated blood in the tissues outside the blood vessel. Sir George Makins observed quite a number of similar instances in World War I.

In seven cases (five gunshot wounds, one shell wound and one bomb wound) or in one-fourth of the total cases, the high-velocity projectile perforated or penetrated the tissues about $1\frac{1}{2}$ inches to $\frac{1}{2}$ inch from the main artery. There was no naked-eye structural damage of the vessel yet the latter exhibited segmental contraction. Evidently concussion violence reacted on the vessel wall. In sixteen cases, the vessel was contused, lacerated, ruptured or perforated.

Regarding the two non-missile compound fractures, the popliteal artery was contused by the jagged margins of the lower fragment of femur in one case, while in the other, the posterior tibial artery was found to have been pierced and kept tethered over a projecting spike-like process of the lower tibial fragment. Both the vessels were thrombosed at the site of injury, besides being contracted.

Regarding the two tourniquet cases, both were received from the field ambulances with notes stating that owing to uncontrollable hæmorrhages in the palm and in the calf following shell wounds, tourniquets had been applied in the lower part of the arm and thigh. Both were received within an hour of the application of the tourniquets. Apparently they had been applied very tightly, as their release left furrows $\frac{3}{4}$ inch deep in the soft tissues. Neither the release of tourniquets nor rapid infusion of plasma helped in the return of the circulation of the limb. At operation, the lower fourth of the brachial artery and lower fifth of the femoral artery were found to be extremely contracted. As soon as the vessels concerned were lifted from their beds, in the twinkling of the eye the circulation restarted.

Treatment adopted

A. For those cases where concussion violence set up the phenomenon: exposure of the artery, hot saline packing, lifting the artery from its bed or removal of surrounding areolar tissue—one of these measures or a combination of all

sufficed to re-awaken the artery from its 'stupor' and restart the circulation.

B. For those cases where structural damage initiated the phenomenon: resection of the damaged segment of the artery between ligatures made the spasmodic contraction disappear and re-established the circulation with the help of collaterals.

The following non-operative measures were suggested:—

(i) Intravenous injection of papaverin hydrochlor for vasodilatation.

(ii) Para-vertebral injection of novocaine, brachial plexus blocks or spinal anaesthesia to interrupt afferent impulses from reaching the cord.

But these measures were not given trial in the forward area, firstly for the uncertainty of the results and secondly as all wounds were to be opened up ultimately for primary wound excision or débridement.

The phenomenon as described by some of the previous observers

1. After he had exposed the posterior tibial artery of a dog, Hunter (Palmer, 1835) observed it to be 'so much contracted in a short time as almost to prevent the blood from passing through it and when divided, the blood only oozed out from the surface'.

2. A case of gunshot wound in the femoral triangle was described by Kroch (1915), in which the lower limb apparently became cut off from the circulation. At operation 'the artery was found apparently undamaged but contracted to the size of a knitting needle. When the artery was fully exposed, it suddenly dilated to normal size'.

3. Out of the experience of peri-arterial sympathectomy, Rene Leriche observed that as soon as the adventitia of an artery was touched, the artery underwent a localized contraction and became progressively reduced in calibre until it had only one-third or one-fourth of its normal volume over the entire segment that had been touched. The supra- and subjacent segments retained their normal calibre as long as the operative procedure did not concern them. 'Sometimes the simple pressure of the bistouri on the neighbouring muscles and indirectly over the common vascular sheath sufficed to fix the artery immovably in contraction'.

Discussion

The phenomenon is a reflex vasoconstriction, the afferent impulses originating in the injured segment. The proof of this statement lies in the fact that excision of the injured segment does away with spasmodic contraction.

The older physiologists did not believe in the existence of the sensory fibres of the blood vessels. Their existence is now proved. Hirsch (1926) has demonstrated, in the adventitious

coat of the peripheral vessels, encapsulated end-organs, tree-like or brush-like structure, which are terminations of autonomic afferent nerves.

The mode of distribution of autonomic fibres in the limb blood vessels will explain some aspect of the phenomenon described above. The main blood vessel of a limb is at its commencement innervated by fibres derived from the ganglionated sympathetic trunk (Kramer and Todd, 1914) in the case of the upper extremity, and from the continuation of the aortic plexus over the common iliac and external iliac vessels in the case of the lower limb (Woollard, 1926). These fibres extend only as far as the axilla or groin. Thereafter the limb vessels receive contributions from the neighbouring nerves at different levels (Hirsch, 1925), or in other words the innervation becomes more or less segmental: hence the segmentary contraction.

The number of branches joining the vessels of the extremities from the adjacent nerves is far greater and total extrinsic nerve supply is far richer than has hitherto been assumed (Kuntz, 1945). According to Burns *et al.* (1937) the proximal portion of the vascular tree is innervated with far less sympathetic fibres than the more distal portion innervated through the limb nerves. This will explain the comparative rarity of the phenomenon in the large blood vessels.

The phenomenon of contraction lasts for at least 24 hours and in some instances may continue for three or four days. Left to itself the distal pulse may then return but by that time muscles are all gangrenous.

The reflex vasospasm is undoubtedly a protective device of nature against the danger of bleeding to death after severe vascular trauma. The subject escapes from the danger of imminent death and may later on pay the price in the shape of ischaemic contracture or gangrene of the limb.

Summary

1. Traumatic arterial spasm or reflex segmentary vasospasm found in 27 cases out of a series of 567 battle casualties is described.

2. Besides direct trauma, concussion set up in the vicinity of the main vessel by the passage of high-velocity projectile or even pressure on the artery from outside are productive of the phenomenon.

3. Segmentary spasm and greater incidence in the medium and small vessels are explained on the anatomical basis of distribution of autonomic fibres to the vessels.

SUPRAPUBIC PROSTATECTOMY WITH SPECIAL REFERENCE TO PENICILLIN TREATMENT

By RAI SAHIB A. D. BHANDARI, F.M.S.

Medical Officer In-charge, District Hospital, Bareilly, U.P.

SOME persons after the age of 50 years get retention of urine as a result of hypertrophy of the prostate gland. This hypertrophy of the gland may attain a considerable size even as big as one's own fist, the normal weight of the prostate being only 18 grammes. Histologically this enlargement consists of overgrowth of the glandular tissue in the form of multiple adenomata, in some cases cystic changes are also observed and occasionally a few fibromyomata are also seen. Malignant disease may supervene in about 10 per cent of the cases. The enlargement of the gland may be hard or soft and in the latter case extremely vascular. Even in early stages of the enlargement it is liable to sudden attacks of congestion and in the early stages this congestion can be relieved by medical treatment but later on hypertrophy of the gland reaches to such an extent that medical treatment proves of no avail. The general health of the patient is slowly undermined due to the constant irritation, frequency of micturition, want of sleep and gradual toxic absorption.

In early stages these patients usually take to catheter life and seek admission to the hospital only when there is complete retention of urine and/or catheterization becomes difficult due to inflammation of the posterior and prostatic urethra.

In the series of cases noted below who came under the treatment of the writer mostly from the rural side of the Rohilkhand Division, U.P., during the last two years the following line of treatment was adopted with successful results. Special attention was paid to avoidance of urethral instrumentation as far as possible as most of the patients had already undergone frequent catheterization before coming to the hospital, in some cases there being false passages and almost all had some degree of cystitis, secondly decompression by the suprapubic route and thirdly prostatectomy in two stages. On admission to the hospital if there is complete retention of urine the patient is immediately prepared for suprapubic cystotomy which is done under local anaesthesia in order to avoid

pulmonary complications as most of these patients are subject to bronchitis. After this preliminary cystotomy there is a marked improvement in the general outlook of the patient. In mild cases a simple diuretic mixture with hexamine is given.

In cases where there is much congestion of the prostate due to cystitis this preliminary cystotomy relieves the congestion and in those cases where both the lobes are not hypertrophied the patient can pass urine freely. One such patient (case no. 12) was admitted with retention of urine and suprapubic cystotomy was done in December 1945. He felt so relieved that he did not consent to prostatectomy at that time and had to come again after 18 months for removal of the prostate. After cystotomy usually a patient is ready for prostatectomy in about 2 to 3 weeks time. For about a week prior to prostatectomy the patient is put on calcium lactate 15 grains three times a day and in some cases a few calcium gluconate, 10 per cent 10 c.c., injections are given. Patients who showed unusual bleeding during the first operation are also given a few injections of vitamin K prior to the second operation. If the systolic blood pressure be below 100, care is taken to bring it to at least 105 by general tonics and careful dieting.

Prostatectomy is done under general anaesthesia. After the enucleation of the prostate complete toilet of the prostatic cavity is done by gauze pack which is changed on the third day. The cavity is repacked if there be slightest indication of oozing of blood, otherwise a rubber tube is put in for drainage.

Restlessness is always complained of after this operation and this is relieved by bromide and chloral each 20 grains in 6 oz. normal saline per rectum. In one case the patient was given an injection of morphine. This relieved him much but there was complete suppression of the urine for about 8 hours and patient ultimately recovered after hypertonic saline and glucose injections. Sulpha drugs were not used as they cause suppression of urine—the kidneys in these cases being not healthy due to constant back pressure.

Penicillin treatment.—For fever and secondary infection patients were put on penicillin treatment. The mode of giving penicillin in all the cases was as follows: A solution of sodium salt of penicillin (containing 100,000 units) in 20 c.c. sterile normal saline was used and of this solution 4 c.c. (containing 20,000 units) were injected intramuscularly every 3 hours—syringe being sterilized by boiling and the penicillin solution being always kept in refrigerator. The time for stopping penicillin injections was determined by a fall of temperature and pulse rate to normal level and aseptic condition of the wound. Minimum period of penicillin injections was 3 days and maximum 12 days. This generally improved the prognosis. One of the very common complications in these cases is atony of

the bladder. The following mixture gave good results :—

Acid hydrochlor dil. ℥ x
 Liq. strychnine hydr. ℥ iii
 Aqua oz. 1
 Twice daily after meals for about
 10 to 15 days.

Summary

1. Thirteen cases of prostatectomy are reported. Eleven were done in two stages and two in one stage. Twelve cases were discharged cured and one died.

2. Prostatectomy in two stages is relatively a much safer procedure. It gives the patient

Case notes

Serial number	Name, age and caste	Course of the case in brief	Result.
1	Ali Bux, 60 years, Mohammedan (male).	Admitted 16-7-45, suprapubic cystotomy 18-7-45, prostatectomy 6-8-45. Glucose 25 per cent 40 c.c. intravenously on the day of prostatectomy. Course protracted—attack of enteritis. Symptomatic treatment and liver injections for 3 weeks.	Cured 21-9-45.
2	Hidayat Ullah, 64 years, Mohammedan (male).	Admitted 28-8-45, severe cystitis—BP 95/65. Suprapubic cystotomy 31-8-45, prostatectomy 17-9-45, fever for 7 days 99 to 103°F. Hypostatic congestion of lungs, morphia injection given after prostatectomy resulting in suppression of urine for 8 hours, function of kidneys restored with glucose and saline injections. Penicillin course for 7 days, progress slow. Vitamin B oral given to tone up general health.	Cured 26-12-45.
3	Mohabbat, 50 years, Mohammedan (male).	Admitted 3-10-45, severe cystitis, suprapubic cystotomy 9-10-45, prostatectomy 12-11-45. Glucose and calcium gluconate injections, fever for 4 days 99 to 101°F. Hypostatic congestion of lungs. Penicillin course for 7 days.	Cured 26-12-45.
4	Imam Bux, 55 years, Mohammedan (male).	Admitted 19-11-45; suprapubic cystotomy 22-11-45, prostatectomy 10-12-45, glucose 25 per cent 80 c.c. and calcium gluconate injections on the day of prostatectomy followed by 80 c.c. glucose intravenously in the next 2 days. Progress satisfactory.	Cured 13-1-46.
5	Mohd. Ishaq, 65 years, Mohammedan (male).	Admitted 7-4-46, severe cystitis, suprapubic cystotomy 9-4-46, prostatectomy 29-4-46, glucose 25 per cent 50 c.c. intravenously after operation, had hypostatic congestion of lungs. Penicillin course for 4 days.	Cured 26-6-46.
6	Man Singh, 60 years, Hindu (male).	Admitted 22-4-46, prostatectomy one stage operation 26-4-46. calcium gluconate and glucose intravenously before and after operation. Rectal saline and glucose after operation. Temperature 99 to 102°F. for 5 days. Penicillin course for 5 days. Progress satisfactory. Duration comparatively short.	Cured 7-6-46.
7	Farhat Husain, 55 years, Mohammedan (male).	Admitted 2-5-46, severe cystitis, albumin in urine ++, acetone +, blood urea 56 mg. per cent on admission. Heart slight dilatation, suprapubic cystotomy 6-5-46, vitamin K 3 injections. Blood urea 20 before second operation, prostatectomy 7-6-46, glucose and calcium gluconate intravenously. Penicillin course for 12 days, vitamin B and iron tonics.	Cured 15-7-46.
8	Chait Ram, 60 years, Hindu (male).	Admitted 28-7-46, suprapubic cystotomy 2-8-46, prostatectomy 20-8-46, glucose 25 per cent 40 c.c. intravenously before and after operation. No complications.	Cured 22-9-46.
9	Abdul Ghani, 60 years, Mohammedan (male).	Admitted 21-8-46, suprapubic cystotomy 26-8-46, prostatectomy 21-10-46. No complications.	Cured 20-11-46.
10	Iswari, 60 years, Hindu (male).	Admitted 25-11-46, general health good, suprapubic cystotomy 27-11-46, prostatectomy 13-12-46, calcium chloride 10 per cent 10 c.c. and glucose 25 per cent 50 c.c. intravenously after operation. Penicillin course for 3 days. No complications.	Cured 22-1-47.
11	Dori Lal, 70 years, Hindu (male).	Admitted 15-3-47, suprapubic cystotomy 17-3-47, prostatectomy 7-4-47, glucose 25 per cent 50 c.c. on the day of operation. Penicillin course for 4 days.	Cured 11-5-47.
12	Ram Chandra, 50 years, Hindu (male).	Admitted 9-12-45, suprapubic cystotomy 12-12-45. Discharged from the hospital on 25-1-46 when he could pass urine freely and did not like to undergo operation for prostatectomy. Re-admitted for retention of urine 28-5-47, prostatectomy performed on 30-6-47 in one stage. There was also a small stone impacted in the prostate. Penicillin course for 6 days.	Cured 1-7-47.
13	Peer Bux, 60 years, Mohammedan (male).	Admitted 7-11-45, albumin +, heart sounds weak, suprapubic cystotomy 12-11-45, prostatectomy 7-12-45, temperature for 2 days up to 100°F. only. Condition went on getting low after operation. Glucose 25 per cent 50 c.c. daily for 10 days. Coramine and other cardiac tonics given without much relief.	Died 14-1-46.

time to build up an immunity against infection and a chance for the renal function to improve. Thus prostatectomy in two stages despite its obvious disadvantages is a sound procedure to adopt particularly by those surgeons who have to treat such patients in surroundings not suited to specialized surgery.

3. Penicillin is by far the safest and best remedy to check secondary infection.

My thanks are due to Dr. P. N. Khanduri, P.M.S., Second Medical Officer in Sub-charge, for his assistance.

[The supervision of malignancy is no longer accepted generally.—EDITOR, I.M.G.]

ANALYSIS OF SURMA

By KUNDAN SINGH, M.Sc.

(From the Department of Pharmacology and Therapeutics, King Edward Medical College, Lahore)

SURMA is traditionally used as an application to the eyes in children of both the sexes, and in

be due to the insidious type of lead poisoning. Frequent abortions and sterility in women may, in the absence of other causes, be due to lead alone.

In view of these facts, it was thought desirable to find out the composition of surma as sold and used in the Punjab. Twenty samples have been examined. They have all been found to be lead sulphide (galena).

It would be interesting to find out if the application of surma can cause lead poisoning.

Experimental.

Lead, antimony, zinc, iron, and sulphur were estimated gravimetrically as lead sulphate, antimony oxide (Sb_2O_3), zinc pyrophosphate, ferric oxide and barium sulphate respectively. Copper was estimated volumetrically by titration with thiosulphate (Naish and Clennell, 1929).

Analysis of different samples of 'surma'

Number	Pb, per cent	Silicious matter, per cent	Cu, per cent	Antimony, per cent	Iron, per cent	Zinc, per cent	Sulphur, per cent	Silver

grown up girls and women. It is supposed to act as a tonic to the nerves of the eyes and to strengthen the sight.

In books on indigenous drugs in English, it is described both as trisulphide of antimony and lead sulphide (Ainslie, 1813; Chopra, 1933; Dey, 1896; Naish and Clennell, 1927; and Watt, 1889).

In connection with the investigations on lead content of normal human tissues, excreta and hair, it was found by Bagchi (1941) that hair of Hindu women was very rich in lead. The source of lead was traced by him to be cheap vermilion which contains red lead, the lead being absorbed through the scalp where it is applied. This was indicated by high lead figures of the urine and faeces of these women.

It was further suggested by him that some common ailments, such as anaemia, menstrual troubles, frequent abortions, dyspepsia, nervous troubles, high blood pressure, weariness of brain and body, etc., which are frequently met with among Hindu women, especially in Bengal, may

Summary.

Twenty samples of surma as sold in the bazars of the Punjab were collected and analysed. These were found to be galena.

I am grateful for the suggestion of the problem and guidance to Dr. Khem Singh Grewal, Ph.D. (Cantab.).

A Mirror of Hospital Practice

PENICILLIN IN SUBACUTE NEPHRITIS

By H. C. JAIN, M.B., B.S. (Bom.)

Chandan Nivas, Ajmer

S., FEMALE, age 4 years.

Present complaints.—1. Swelling of the eyelids, face, abdomen, legs and forearms.

2. Irritative cough.

3. Intermittent attacks of fever.

Origin, duration and progress.—About three months back the child got an attack of pain in the right leg and after five days of this attack swelling in the eyelids and legs was observed one morning.

The swelling of the eyelids and legs almost disappeared after twenty days of treatment though the child continued to have pain in her right leg all this time.

The swelling then increased and extended to abdomen and forearms as well.

The irritative cough set in about 22nd February and has since then persisted.

The fever was intermittent and never rose higher than 102°F.

Past history.—The child had an attack of double pneumonia about two years ago.

Previous medications.—Iron diuretic mixture, alkaline diaphoretic mixture, and neptal tablets were all tried. The cedema with administration of neptal tablets increased considerably.

I was called to see the case on 5th March.

Examination.—Face swollen more so in the region of eyelids. Conjunctiva pale; nails pale. Tongue clean and moist. Throat congested. Skin—shiny and tight over face, legs and abdomen. Pitting on pressure on the dorsum of foot extending up to the knee-joints.

Alimentary system.—Abdomen was full. Umbilicus was transversely stretched. Percussion dullness in the flanks. Fluid thrill was positive. Liver was palpable four fingers and softish in consistency.

Cardiovascular system.—Pulse 80 per minute. Rhythm regular. Force good. Tension fair. Heart borders normal. Heart sounds normal.

Respiratory system.—Rate 20 per minute. Rhythm regular. Both sides moving equally. A few basal râles were audible.

Urine examination.—Urine: Reaction varied. Specific gravity 1012 to 1020, albumin present. Granular and epithelial casts in the beginning only. Pus cells in the beginning only.

Diagnosis.—A diagnosis of subacute nephritis was made on the pathological basis of a septic focus in the tonsils and parenteral administration of penicillin began, though with some diffidence because of the subacute nature of the case.

In all it was aimed to give two lac units of penicillin sodium in twenty intramuscular

injections with a concentration of 10,000 units per c.c. in normal saline made with pyrogen-free distilled water at three hourly intervals.

After the administration of a lac units the child became extremely needle shy and it was decided to give three more injections only with a concentration of 25,000 units per c.c. making a total of 175,000 in all.

The needle and the syringe were boiled every time and ether was employed to sterilize the skin and the cap of the penicillin vial which was kept in ice when not being used.

Side by side a citrate diuretic mixture was given.

Diet.—No salt was given. Honey was given, also weak tea, milk, orange and lime juice, salt-free butter and toffee.

A dramatic improvement was noticed on the third day after the course of penicillin when a profuse diuresis set in and continued on the fourth day as well by which time there was not a trace of cedema left all over the body. The albumin however continued to be present though in diminished quantity.

AN UNUSUAL CASE OF SUPPRESSION OF URINE

By N. K. GUHA NIYOGI, B.S.C., M.B.

Chapai-Nawabganj, Malda

I was called in the early morning of 27th March, 1947, to attend a case of suppression of urine in an unmarried girl of 16. I was told that she had last urinated at 11 a.m. of 26th March, 1947. She had passed a very restless time after the suppression. I reached the place at about 1 p.m. and found her screaming.

On my arrival I was shown the huge swelling at the lower abdomen. As the mass was the distended bladder and as she was screaming, I, at once, made up my mind to relieve the bladder first and then to investigate the matter in details. She was put on the end of a bedstead for easy work.

On exposing the external genital organs, I noted:—

1. The vestibule of the vagina—the part stood out very prominent, seemed bulged and pushed forwards, making the labia gape apart.

2. The urethral opening seemed pushed upwards as far as the clitoris.

3. There was a complete septum across the vagina—imperforate hymen. The septum was very tough and thick.

To me, it seemed, at the outset, that all these troubles were due to the internal pressure caused by the distended bladder.

The part was thoroughly washed and catheter was passed. As the urethra was pushed upwards, I experienced some difficulty in passing the catheter. However a huge quantity of urine came out and the patient got immediate relief. Though a huge quantity of urine was drawn, still no change in the external genital organ was noticed, which struck me most.

Past history.—1. Burning sensation during micturition—duration 2 to 3 years.

2. She had to strain sometimes before the actual flow of urine commenced. At the beginning, urine came out in drops then in flow—duration about 2 to 3 years.

3. No history of appearance of menstruation.

4. She admitted that she used to get some painful sensation and some heaviness in the waist every month lasting for 3 or 4 days—duration 2 to 3 years.

On examination I found :—

1. A tough and thick membrane completely closing the vagina. The area of the vestibule was pushed forwards. This portion stood out very prominent separating the labia wide apart.

2. On rectal examination a huge mass (hard to feel, but not as hard as stone) was palpable between the finger inside the rectum and the finger placed over the lower abdomen.

3. A mass was also felt between the finger inside rectum and that over the vestibule.

4. The girl was 16 years old, still she did not show any marked development of the sexual organs—the breasts not much developed, no pubic hair.

From all these I diagnosed the case to be suppression of urine caused by accumulation of menstrual blood inside the vagina, which was closed by imperforate hymen. I thought of making an incision and removing the cause of the suppression. But I was not prepared for it.

Next day I was again awakened from my bed for the same troubles. I was told that there was no urine since the last catheterization. I reached the place at 2 p.m. That day the urethra seemed to be more pushed upwards for which I had to pass the catheter with some difficulty.

I made an exploratory puncture, with a needle fitted to a hypodermic syringe, in the tough membrane (hymen) to aspirate fluid, if any. Inside the syringe I found some black, thick tarry fluid. This confirmed my diagnosis. I incised the hymen. On opening, a huge quantity (about 1½ seers) of thick, black tarry fluid (accumulated menstrual blood) came out of the vagina. There was no clot in it. After this, no mass could be felt rectally nor was any bulging of the vestibule seen separating the labia. The patient is now doing well.

Points to note.—1. A girl of 16 with imperforate hymen. The hymen formed a complete septum. There was atresia of the vagina causing no symptoms until the onset of puberty.

2. Menstruation started long ago without appearance of any flow—apparent amenorrhœa.

She felt general discomfort and usual symptoms of approaching menstruation without any actual flow.

3. Menstrual blood accumulated inside the vagina for some years and a huge mass 'Hæmatoecolpos' was formed which compressed the urethra causing the suppression of urine. Burning sensation during micturition and straining during micturition with coming of urine in drops were all pressure symptoms.

DELIVERY OF A DEAD FŒTUS PER RECTUM

By S. K. SRIVASTAVA, L.M.F.

*Medical Officer, I/C Hospital Nagod, C. I.

THIS type of case rarely presents itself and it is therefore thought that report on such a case would be of interest.

A female Mohammedan, aged about 35 years, came to the Hospital Nagod in a bullock cart from Bundelkhand on 24th March, 1947, with the complaints of constant pain in the abdomen and offensive discharge of pus through the rectum.

The patient was very much debilitated, anæmic, and could neither stand erect nor walk. She had temperature 99°F. and the pulse rate was 120 per minute.

Past history.—Three years back she had given birth to a child who was born healthy but died after 6 months. She gave no specific history of syphilis or gonorrhœa. She conceived again and carried 8½ months till the end of the month of December 1946. She had pain in the abdomen throughout the whole period of confinement.

As she was illiterate and a village woman, she did not mind the trouble or worry about the consequences. At the end she felt no movement of the fœtus in the abdomen, believed the child was dead, even then she did not mind and carried on.

By and by as the days passed she began to get discharge of pus and offensive fluid per rectum and believed the dead fœtus had begun to come out part by part and thus in a few days she would get rid of it. Thus three months passed away. Now when attendants thought she had become bed-ridden and there was no hope of her surviving they brought the case to the hospital for the proper treatment.

I did not believe the history of the fœtus being cleared off through rectum.

Palpation.—Lump of swelling felt above the pubis up to 2 inches below the umbilicus.

P. V. examination.—Cervix contracted. External os so much constricted that even the uterine sound could not be passed in.

Rectal examination.—I passed my finger in the rectum, some foul discharge of pus came out. I felt some hard, long, stick-like thing against my finger. By manipulation I could

take out the same and to my surprise it was the radius of the foetus. Further, I manipulated and saw a big, two fingers' breadth, fistula in the rectal wall between the lower and posterior part of the uterus and rectum (utero-rectal fistula) through which I could feel a heap of bones inside.

Next day under chloroform anaesthesia, firstly I tried to dilate the cervix but it was so badly contracted that I had to discard this route. Then through rectum I dilated the fistula; by manipulation, with finger I removed all the remnant of the dead foetus—putrefied portion of organs and bones of skull, face, ribs and limbs. In between operation I washed and flushed out all the debris inside the uterus by douching with dettol lotion through the opening of the fistula. I cut clean the ragged margins of the fistula and left it open.

The patient was given glucose saline intravenously and brought to the inpatient ward.

She was given ergot quinine mixture to promote contraction of the uterus, and to prevent further infection, cibazol with alkali was given orally.

Daily douche of dettol lotion per rectum was administered. After a week iron mixture as tonic was given.

At the end of the 3rd week the fistula healed and the patient was discharged cured on 15th April, 1947.

She regained her health and became able to walk to her relation in the town.

I advised her to keep on taking some general tonic.

Conclusion

1. The admirable tolerance of the patient that she could keep full-term dead foetus for 4 months with no serious effect.
2. She did not develop sepsis having such an open chance.
3. Delivery of the whole skeletal part of the foetus per rectum.
4. Rapid healing of the fistula and uneventful recovery of the patient.

AN UNUSUAL CASE OF ILEO-CÆCAL TUBERCULOSIS

By A. K. BASU, M.S. (Cal.), F.R.C.S. (Eng.)

Teacher of Surgery, Campbell Hospital Medical School, Calcutta

THE frequency of tuberculous involvement of the ileo-cæcal region as a cause of chronic indigestion is only recently being realized. Formerly it was considered as one of the rare causes of a lump in the right iliac fossa. More and more cases are being recognized and successfully operated upon nowadays. During the last 12 months, the author has come across at least 12 well-authenticated cases.

The case described below presented certain peculiar features which makes its publication worth while.

Case report

S. L. D., 22, Hindu female, complained of occasional vague abdominal burning pain and indigestion for 6 months. She was rather uncertain about the exact nature of the pain and besides its being felt mostly in the right lower quadrant of the abdomen could not give more details about it. The pain had no relation to food. She also had anorexia and had lost a certain amount of weight during the last year.

She had also felt an occasional lump in the right iliac fossa and in fact had been admitted into the hospital as a case of suspected appendicular lump.

About a year ago, she had been admitted into the gynaecological ward of the hospital and had undergone an abdominal operation.

On admission.—She was a small frail woman, anæmic. There was a 4 inches midline lower abdominal scar.

A lump, size 2 inches \times 2½ inches, was easily felt in the right iliac fossa. It was slightly tender on pressure, freely movable in all directions and dull on percussion. Peristaltic sounds were normal.

P. V.—No abnormality was detected.

Investigation

Blood.—Hæmoglobin 55 per cent, red cells 2,800,000, white cells 8,500, polymorphonuclears 70 per cent.

Barium enema.—It showed a filling defect in lower half of ascending colon and cæcum. According to the radiologist the colon was very irritable and the meal very quickly passed through it into the small intestine—suggesting irritable colon? T.B.

Stool examination.—Normal.

Operation

Rectal paraldehyde and open ether were used. Right paramedian incision, 5 inches long, was made.

The mass was easily found in the right iliac fossa. It was much larger than could be felt manually before. It involved the cæcum, lower half of ascending colon and last 2 inches of ileum. It was firm and there were large numbers of nodules on the surface. Large masses of glands were palpable in the mesentery. The glands were firm but not hard as one would associate with malignancy. The colon was mobilized by incising the peritoneum in the right paracolic gutter. Mobilization was remarkably easy.

Right hemicolectomy was done by the method described by Rodney Maingot. Some difficulty was experienced in the excision of the mesentery owing to the very large number of enlarged glands present. About 6 inches of ileum were removed and the anastomosis of the ileum to the transverse colon was of the end to side variety, the open end of the transverse colon being closed. The V-shaped gap in the mesentery was closed

by suturing its cut margin to that of the transverse mesocolon and the posterior peritoneal wall repaired in the usual way.

The patient stood the operation well, and recovery was uneventful, except that she had diarrhoea on the 4th and 5th post-operative day, probably due to errors of diet.

About 3 weeks after the operation she developed an abscess in the abdominal parietes which healed after incision.

Points of interest

1. No significant symptom except occasional vague abdominal pain, dyspepsia and anorexia.
2. Free mobility of the lump.
3. Large number of nodules present on the surface.
4. Easy separation of the mass.

Pathological report

(S. Bhattacharya)

The mass: 1. *Macroscopic examination.*—The specimen consists of about 6 inches of ileum, caecum, appendix, ascending colon and about 4 inches of transverse colon. The area of the caecum and the lower half of the ascending colon is occupied by a large indurated mass, which shows the presence of numerous fair-sized tubercles on the surface (size of mustard seeds). The indurated area extends on to about 3 inches of ileum.

2. *Microscopic examination.*—(1) Giant cells of tubercular type, fair number; (2) much lymphocytic infiltration; (3) large amount of fibrosis; (4) caseation not much in evidence.

The lymph glands: 1. *Macroscopic examination.*—(1) Enlarged; (2) cut surface homogeneous, caseation not seen.

2. *Microscopic examination.*—(1) Giant cells, fair number; (2) marked fibrosis replacing the lymphoid tissue which is not much in evidence; (3) caseation—very little.

Diagnosis

Tubercular intestine, hyperplastic type.

A CASE OF HYPERTENSIVE ENCEPHALOPATHY WITH SUBARACHNOID HÆMORRHAGE IN ACUTE DIFFUSE GLOMERULO-NEPHRITIS

By M. BASAVARAJ URS, B.Sc., M.B., B.S.

Assistant Professor of Medicine and Assistant Surgeon, Krishnarajendra Hospital, Mysore

A SIXTEEN year old married girl entered Krishnarajendra Hospital, Mysore, on 8th March, 1947, with complaints of oedema of the face and lower extremities and scabies for the past fifteen days. One year before admission she had an attack of scabies which was treated and cured.

On admission, the girl was conscious, the feet were swollen, and lesions of scabies with

secondary infection were found all over the body specially over the hands and feet. Blood pressure was 130/90 mm. of Hg. Urine revealed albumin +++, R.B.C. ++, and casts ++, and was high coloured with a specific gravity of 1025. There were no signs of upper respiratory infection. Pupils were normal. The heart was not enlarged. The sounds were of good quality. Lungs were normal. Liver and spleen were not palpable. W.B.C. count was 11,500 c.mm., R.B.C. count 3.5 million per c.mm., Hb. 75 per cent, sedimentation rate 40/10, blood urea 35 mg. per cent.

A diagnosis of acute nephritis with hypertension was made, the aetiological factor probably being pyoderma. After five days' stay in the hospital, she started complaining of headache and slight dimness of vision. The headache became intense towards the evening and the vision was almost lost. She vomited about six times and it was projectile in nature. At 6 p.m. on the same day she developed an epileptiform seizure which lasted for 2 minutes and became unconscious after the attack. Soon after the attack, the blood pressure was 150/110 mm. of Hg. She spent the night unconscious with six more attacks of convulsions, incontinence of urine and faeces, and frequent vomitings. The next morning, lumbar puncture revealed hæmorrhagic fluid which was under high tension. The fluid was intimately mixed with blood and never became clear even after taking a test-tubeful of fluid with frequent change in the position of the needle. The fluid did not clot on standing. On centrifuging, there was xanthochromia. There was no increase in the number of leucocytes and no micro-organisms could be detected under the microscope. The blood pressure was 140/110 mm. of Hg. On physical examination, there was paresis on the left side of the body with rigidity of the neck and a positive Kernig. She was found to curl herself to the left. Pupils were normal and fundi were normal. She was put on intravenous glucose 50 c.c. 25 per cent twice a day with injections of luminal and oral bromides. She was also put on penicillin 20,000 units every three hours. Within twenty-four hours the convulsions ceased. She regained consciousness, and complained of severe headache and dimness of vision. The lumbar puncture was repeated which had the same characteristics as before. Blood pressure had come down to 130/100 mm. of Hg. Blood urea was 45 mg. per cent. Paresis of the left side of the body, nuchal rigidity and Kernig's sign were still present. The treatment was continued with absolute rest in bed and orange juice. Four days later the patient was found to be quite conscious, speech was rational, external stimuli were appreciated. The quantity of urine passed by this time was 40 oz. a day. Blood pressure was 130/90 mm. of Hg. There was improvement in the paresis. Nuchal rigidity and Kernig's sign were negative. Lumbar puncture

revealed no pressure, the fluid coming out in drops in contrast to the continuous stream in the first two punctures. The fluid was coloured yellow and on microscopy there were no red cells nor leucocytes.

After a stay of twenty-eight days in the hospital she was discharged at her request with instructions to come and report after a month. At the time of discharge there was no oedema, blood pressure was 110/85 mm. of Hg., blood urea 35 mg. per cent. Few granular casts and few red cells were found in the urine and albumin was in traces. Scabies had been cured.

She was prompt in reporting her condition exactly a month later. Except for eczematous ulcerations around the waist, nothing abnormal was detected on physical examination. Urine was free from albumin, red cells and casts. Urine output was between 40 to 50 oz. a day. Blood pressure was 110/80 mm. of Hg. After a stay of one week, the ulcerations around the waist disappeared with local application of calamine lotion, oral cibazol and intravenous caluseptasine.

Comment.—The first thing that strikes in the differential diagnosis is an accidental puncture of the spinal veins. The fact that the fluid did not become clear with the change in position of the needle, the intimate mixture of the blood with the cerebrospinal fluid, the absence of clotting and the presence of xanthochromia speak strongly against the accidental puncture. Acute meningitis is out of question in the absence of an increased number of leucocytes and micro-organisms in the fluid. Rupture of a berry aneurysm either spontaneous or as a result of an increased arterial tension is the only other alternative diagnosis. But the cerebral episode in association with increased cerebrospinal pressure and increasing arterial tension is more in favour of hypertensive encephalopathy.

In the acute stages of glomerulo-nephritis, it is the danger to the heart and to the brain which is of first and highest importance rather than to the kidney itself. 'Almost every case that dies in the acute stage of this disease dies of cardiac insufficiency'.—Volhard. The danger to the brain though less frequent is more startling and dramatic because of the cerebral oedema causing the convulsions of the so-called eclamptic uræmia, which has nothing to do with the uræmia caused by renal insufficiency. This cerebral-symptom complex is termed hypertensive encephalopathy by Oppenheimer and Fishberg. It is to be noted that the higher the blood pressure the greater the danger to the brain. Headache becomes intense accompanied by vertigo. Vomiting is projectile and without effort. Amaurosis affects both eyes, the vision returning to normal within a few hours or days if the patient survives. The blood pressure is high before and during the attack. The cerebrospinal fluid is under increased pressure, the fluid gushing from the needle in a steady

stream. Though unusual, it is possible to find blood in the cerebrospinal fluid. One case has been reported by Dewar and Walmsley (1945) where subarachnoid hæmorrhage was detected at post mortem in a case of relapsing fever with acute glomerulo-nephritis. The possibility of hæmorrhage into the subarachnoid space should be in mind whenever the epileptiform seizures are preceded by nuchal rigidity, a positive Kernig and an increasing blood pressure. 'It seems likely that . . . the cerebral arterioles are unable to constrict with the force necessary to keep pace with the great rise in arterial pressure; the result is that blood enters the cerebral capillaries under preternaturally great tension and transudation is augmented'.—Fishberg (1939). The already injured capillaries as a result of generalized capillaritis may have to yield to this preternatural great tension.

My thanks are due to Lieut.-Colonel R. Nagendran, B.Sc., M.B., B.S., F.R.C.S. (Eng.), Medical Officer, Krishnarajendra Hospital, Mysore, for having permitted me to utilize the materials from the hospital.

A CASE OF BLACKWATER FEVER

By R. N. CHAUDHURI, M.B., M.R.C.P. (Edin.),
 T.D.D. (Wales)

and

H. CHAKRAVARTI, M.B. (Cal.)

From the Department of Tropical Medicine, School of Tropical Medicine, Calcutta

GUPTA *et al.* (1942) reported on the anti-hæmolytic property of *Vitex peduncularis in vitro*, while clinically Chaudhuri and Rai Chaudhuri (1945) observed its apparent efficacy in a case of quinine hæmoglobinuria. Singh and Singh (1944) claimed uniformly good results with antivenene in blackwater fever cases. No report is yet available to us on paludrine being tried in this disease. The following case in which all the three drugs were tried is therefore worth reporting although none of them seemed to influence the hæmolytic process.

Case report

A Bengali male, aged 24 years, was admitted to the Carmichael Hospital for Tropical Diseases on the 13th January, 1947, for blackwater fever of six days' duration. He lived in a hyperendemic rural area about 30 miles from Calcutta and gave a past history of

having had many attacks of malaria. Two of his brothers died of blackwater fever—one seven years ago and the other only eight days before the patient's admission to the hospital.

The onset of present illness was sudden with rigor and rapid rise of temperature to 104°F ., and he took 10 grains of quinine sulphate by mouth. Three hours after the dose he started passing 'blackwater' and also had nausea and vomiting. Definite jaundice was noticed about the third day. The attending physician kept him on absolute rest and gave alkalies by mouth, daily intravenous injections of glucose, calcium and vitamin C as well as one injection of vitex peduncularis (Pedunculine of Gluconate Laboratories) but to no effect. High remittent type of fever with daily rigors persisted and the quantity of urine gradually diminished.

The patient was brought to hospital very ill. He looked alert and rather apprehensive and complained of nausea and dysuria. He appeared very prostrated, dehydrated and pale. The temperature was 101°F ., pulse rapid and feeble and blood pressure 92/28 mm. of Hg. There was a hæmic murmur in the heart; the lungs were clear and the spleen was just palpable. The urine was very scanty and the specimen presented the appearance characteristic of the disease. It was slightly acid in reaction and loaded with albumin; benzedrine reaction was strongly positive, and on microscopic examination, hyalin and granular casts, few pus cells and very few red cells could be found. Blood examination revealed severe degree of anæmia with positive indirect van den Bergh reaction (see table), while repeated thick films showed no malarial parasites. The Wassermann reaction was negative.

Treatment and progress.—In view of the impending circulatory failure the patient on admission was given a transfusion of 250 c.c. of plasma followed by four-hourly injections of suprarenal cortical extract alternately with coramine hypodermically. He was also given two injections of pedunculine 2 c.c. each on the same day, besides a mild alkaline mixture four hourly. He was kept on complete bed rest and given milk diluted with barley water, orange juice, glucose and plenty of water to drink. (He had practically no food except drinks of barley water, *dab* water and plain water with or without glucose for six days before admission.) A dose of phenobarbitone was given at night to ensure sleep.

14th January, 1947. The general condition of the patient was practically same, but there was profuse diuresis. The urine appeared clearer in the morning but in the afternoon, following a rigor with a high rise of temperature, black urine was again passed. Extract of vitex peduncularis by mouth in daily doses of $2\frac{1}{2}$ oz. was given and continued for five days. Blood pressure 90/32.

15th January, 1947. Diuresis continued, but following another rigor and passage of very dark

urine the patient became extremely prostrated and his general condition deteriorated. A single dose of paludrine 300 mg. was given empirically. Intravenous injections of 50 c.c. of 25 per cent solution of glucose with 400 mg. of vitamin C twice daily were started. He was also put on antivenene intravenously 30 c.c. *stat* followed by 10 c.c. four hourly for three days.

16th January, 1947. The patient was in an alarming state with profound anæmia (hæmoglobin 3.3 gm., 24 per cent), jaundice, persistent hæmoglobinuria and blood pressure 86/34 mm. of Hg. Adequate urinary output was however maintained. A transfusion of 250 c.c. of blood was given very slowly by drip method without any untoward reaction. In the evening following an injection of antivenene he had a severe rigor followed by passage of urine which was darker than any previous sample.

17th January, 1947. The patient appeared a little better. Another blood transfusion was started but severe rigor and high rise of temperature followed after only 50 c.c. were given and it had to be discontinued.

18th January, 1947. The morning specimen of urine was somewhat clearer but again became very dark after a severe rigor in the afternoon following a glucose injection. Blood pressure 83/34 mm. of Hg.

19th January, 1947. The patient's condition seemed to deteriorate, and the hæmolytic process was uninfluenced by antivenene and vitex peduncularis both of which were stopped and so also the glucose injections which were disliked by the patient. He was put on injections of whole liver extract (T.C.F.) as well as ferrous sulphate gr. 6 thrice daily by mouth. The alkaline mixture was continued.

20th January, 1947 to 26th January, 1947. The fever gradually came down; there were slight rigors on 20th and 21st only. The urine gradually became clearer though occasional darker samples were passed. The patient felt hungry and he was fed liberally.

27th January, 1947. Patient afebrile; blood pressure 98/42 mm. of Hg.; urine clear, no albumin.

Convalescence—uneventful. He had altogether 17 injections of liver extract (4 c.c. each) and iron for 21 days. There was steady improvement of the general condition and the blood picture (see table). He was discharged cured on 19th February, 1947.

Thick films were examined for malaria parasites almost daily with negative results.

Points of interest

1. History of blackwater fever in the family.
2. The patient was desperately ill with almost daily rigors, profound anæmia and hypoproteinæmia which was mainly due to reduction of the albumin fraction.
3. Plasma transfusion brought on marked diuresis averting threatened anuria on admission.

TABLE

Date	BLOOD COUNT		M.C.V.	Reticulo- cyte, per cent	Bilirubin, mg. per cent	W.B.C.	PLASMA PROTEINS, GM. PER CENT		
	Hemoglobin, gm. per cent	Red cells per million					Total	Albumin	Globulin
13-1-47	33	1.38	115.9	..	2.5	5,200	5.5	2.8	2.7
16-1-47	24
20-1-47	24	1.04	133.3	2.1	1.5	..	4.8	2.4	2.4
24-1-47	24	0.88	..	33.6	..	6,000
29-1-47	48	2.05	112.2	17.6	0.4	6,000	5.1	2.8	2.3
6-2-47	58	2.65	113.2	8.2	0.2	6,800	6.2	3.5	2.3
19-2-47	84	4.1	96.2	7,200	6.8	4.4	2.4

4. A blood transfusion gave rise to a temporary improvement of the general condition but it could not be repeated a second time owing to severe reaction.

5. Vitex peduncularis and antivenene therapy appeared disappointing; at least they had no immediate good effect.

6. A single dose of paludrine 300 mg. was given without any appreciable effect (good or bad).

7. Improvement of the patient's condition seemed spontaneous after cessation of intensive treatment, and the convalescence was undoubtedly hastened by administration of hæmatinics.

A CASE OF DIABETES INSIPIDUS ASSOCIATED WITH DIABETES MELLITUS

By SACHCHIDANANDA BANERJEE, M.B.,
D.Sc. (Cal.), M.A.D.A. (U.S.A.)

Dr. A. Mitra Research Scholar in Diabetes, School of
Tropical Medicine, Calcutta

THE patient, a married Hindu male, aged 54 years, a collecting sarkar by occupation, was admitted into the Carmichael Hospital for Tropical Diseases on the 13th February, 1947, for the following complaints: polyuria, nocturia, polydipsia, weakness and glycosuria. The duration of all these complaints was only two months. The patient gave a history of syphilis three months back for which he was treated by the venereal department of the Medical College, Bengal.

On admission the patient appeared very ill. As he was excreting sugar in urine the writer

thought that he was developing diabetic coma. His blood sugar was immediately estimated and it was found to be only 100 mg. per 100 c.c. of blood. His blood pressure was 110 mm. of Hg. systolic and 65 mm. of Hg. diastolic. The patient was kept on absolute rest in bed and was given a diet consisting of protein 135 gm., fat 90 gm. and carbohydrate 180 gm. This diet furnished him approximately 2,000 calories. 24-hours' specimen of urine was collected every day.

On the fifth day of his stay in the hospital the patient stopped excreting sugar in his urine although the volume of urine excreted which varied between 5 and 6 litres did not diminish.

FIG. 1.
Glucose tolerance Curves.

An oral glucose tolerance test was performed on the 17th February. The glucose tolerance curve (I) is shown in figure 1. Although the urine did not contain any sugar when the fasting blood was taken the patient excreted sugar after completion of the sugar tolerance test. The glucose

tolerance test showed a diabetic type of curve. The persistence of polyuria, even when the urine was sugar-free, suggested that the case might be a case of diabetes insipidus. The patient was, therefore, given a daily injection of 10 units of posterior pituitary extract. The volume of urine excreted was markedly diminished as a result of the injection. But as soon as the injection was stopped the patient began to excrete a large volume of urine. The volume of urine excreted in different days is shown in figure 2.

FIG. 2.

The effect of a high carbohydrate diet on the glucose tolerance test was also studied. From the 5th of March the patient was given a diet consisting of protein 120 gm., fat 55 gm. and carbohydrate 280 gm. This diet furnished approximately 2,000 calories per day as before. The oral glucose tolerance test was performed on the 12th of March, 1947. The patient excreted no sugar before the administration of glucose but the urine collected two hours after feeding glucose contained sugar. The glucose tolerance curve (II) is shown in figure 1. It will be seen that the high carbohydrate diet further diminished the tolerance to glucose. The glucose tolerance curves indicated that the patient was also suffering from mild diabetes mellitus.

Laboratory findings.—Urine showed presence of sugar for the first five days only. The specific gravity of the urine was 1005 and there was no other abnormality. Blood examination showed a white cell count of 8,900 per c.mm. of blood with 63 per cent neutrophils, 29 per cent lymphocytes, 4 per cent monocytes and 4 per cent eosinophils.

The red blood cells were 4.4 millions per c.mm. of blood and haemoglobin was 14 gm. per 100 c.c. of blood. Stool did not contain any protozoa or ova. The vitamin C nutrition, as determined by the saturation test, was normal. The Wassermann reaction was negative.

X-ray findings.—A skiagram of the pituitary fossa was taken and the radiologist's opinion was 'the pituitary fossa appears to be smaller than normal'.

Discussion.—The excretion of a large volume of very dilute urine of low specific gravity without any traces of albumin or casts, the negative Wassermann reaction, the diminution of the volume of urine after injection of posterior pituitary extract, the smaller pituitary fossa and low blood pressure point out that this was a case of diabetes insipidus. After hospitalization the patient stopped excreting sugar even on a moderately high carbohydrate diet. The lowered sugar tolerance, however, suggested that the patient was also suffering from mild diabetes mellitus. The coincidence of both diabetes insipidus and diabetes mellitus in the same patient is not very common.

[The possibility of a reaction in the pituitary gland, caused by the treatment for syphilis, remains.—Editor, I.M.G.]

A CASE OF MANIACAL EXCITEMENT FOLLOWING LARGE DOSES OF ATEBRIN

By A. R. GOVINDA RAO, M.B., B.S.

RECENTLY I was called to see a person who started behaving like a mad man all of a sudden. Previously he had been quite well and had no such attacks.

The patient was not feeling up to the mark that morning and having felt some chill imagined that he was getting fever and took 2 yellow tablets with a little water. Then he went out for a walk with some of his friends, leaving the house by 10 a.m. and returning by about 1.30 p.m. in the hot sun with bare head. The sun was very severe that day. After returning home he got all of a sudden excited and into a state of anxiety. He was uncontrollable, fretful and raving. He assaulted his father, mother and everybody in the house and was unmanageable. He had sudden attacks of panic in which he rushed blindly out into the open street, wandering aimlessly with ceaseless agitation. With much difficulty he was forced into the house by a number of people and locked up in a room.

I couldn't examine the patient in detail on account of his restlessness. Here are a few findings :—

The patient, a well-built sturdy man of about 25 years, was kept restrained by half a dozen persons. He was abusing them and sometimes spitting also. Pulse 92 per minute. Respiration 25. Temperature (armpit) 99.5. Heart and

lungs—clear. Liver not enlarged. Spleen just felt, eyeballs deviated outwards and upwards. Pupils dilated and sluggish to light. Biceps and kneejerks exaggerated.

Previous history.—The patient was demobilized from military service about a month back. He had come here to stay with his parents. He had told his father that he was getting malarial fever in the army and that he was advised to take regularly some yellow tablets. He had brought a good supply of the same tablets and was taking 2 or 3 tablets at a time once or twice a day and might have consumed quite a sufficient number during his stay of one month here. There was no history of alcohol or tobacco consumption. On further probing I was able to elicit that there were some misunderstandings between the son and the parents on the choice of a bride and that there were some scenes and heated arguments in the house for some days. The precipitating factor for the psychological derangement was there all right.

Now the problem of diagnosis came up. I considered the following for differential diagnosis :

1. Heat exhaustion and sunstroke.
2. Cerebral malaria.
3. Acute alcoholic intoxication.
4. Affective disorder—probably due to the large amount of atabrin or quinacrine consumed.

In heat exhaustion a direct heat action upon the brain occurs in addition to the salt loss and the picture is akin to that of surgical shock. In sunstroke hyperpyrexia will be present. But patient was perspiring well, with no hyperpyrexia and no signs of shock.

Cerebral malaria—temperature 99.5. No malarial parasites seen in thick and thin smears; history of having taken atabrin quite a good dose. All these were against it.

Alcoholic intoxication. Patient's friends and parents vouched that he was a complete teetotaler, never touched alcohol in his life. In addition this is a dry district and alcohol not easy to get. There was no smell of alcohol about him.

So in the end I was left with the affective disorder due to large dose of atabrin.

Treatment adopted.—Morphia gr. $\frac{1}{4}$ given immediately. As the patient had passed urine recently, no catheterization done. Lumbar puncture done—fluid under pressure, clear; no cells or leucocytes, no increase in globulin or albumin.

Blood for M.P. and leucocytosis—no M.P. and moderate leucocytosis. Feeding done through a nasal catheter passed into the stomach (intragastric drip). Nicotinic acid 4 tablets of 50 mg. crushed and dissolved in an ounce of water administered every 6 hourly. Orange juice with glucose, milk, barley water given.

Once paraldehyde with sugar solution given after about 6 hours. Patient had intervals of a few hours' rest.

The same treatment continued next day. The patient was slightly under control still. On the third day he was much better, and began taking interest in his surroundings. Took some milk by mouth and asked a number of reasonable questions. The convalescence was rapid and he became completely normal. He had 2,400 mg. of nicotinic acid in 3 days.

Subsequently I took the patient's blood pressure and examined his urine but could not find anything abnormal. He admitted to have consumed nearly 80 tablets of quinacrine within 30 days.

Therapeutic Notes

NOTES ON SOME REMEDIES

XI. ANTIMONY AND ITS DERIVATIVES (Part II)

By R. N. CHAUDHURI, M.B. (Cal.), M.R.C.P. (Edin.),
T.D.D. (Wales)

*Professor of Tropical Medicine, School of Tropical
Medicine, Calcutta*

Therapeutic Uses

1. LEISHMANIASIS

1. *Kala-azar (visceral leishmaniasis).*—In this condition the pentavalent compounds are preferable, but in the following account tartar emetine has been included because it has the advantage of being a very cheap drug. For reasons of space only a few selected drugs are detailed below :

(1) *Antimonyl tartrates.*—The sodium salt is somewhat less toxic and irritant than the potassium salt, but both are used in the same manner and doses. A 2 per cent solution in sterile water or normal saline is prepared for the injection; it will keep for some weeks if 0.5 per cent carbolic acid is added, but before use it should be examined carefully to see that there is no precipitate. The initial dose in an adult is 2 c.c. and is increased by 1 c.c. at a time up to a maximum dosage of 5 c.c. Subsequently this 5 c.c. dose is repeated on each occasion. Great care is required to prevent any escape of the solution into the subcutaneous tissue; for if this accident happens, there will be a very painful swelling which sometimes results in sterile suppuration. In children from 10 to 15 years, the first dose is 1 c.c. increased to maximum 3.5 c.c., and in those under 10, the dose is increased from 0.5 c.c. to 2 c.c.

Of the toxic symptoms which follow the injection, the cough is not of much significance. Nausea is an indication against any further increase of the dose so long as it ensues, on the

other hand if there is vomiting, it is an indication for reducing slightly the next dose, increasing again when it ceases to appear.

The length of the course is usually determined by the time it takes to bring the temperature to normal; if this is unduly delayed, it will take longer time and greater amount of the drug to cure the disease. As a general rule, the maximum curative dose of the tartrates is 2.5 to 4 gm. for every 100 lb. of body weight, given in about 25 to 40 injections. The cure rate is about 80 per cent.

(2) *Neostibosan*.—Napier found this preparation the most efficient and least toxic of the pentavalent compounds. It is given intravenously in 5 per cent strength, the first dose being 0.2 gm. and subsequent doses 0.3 gm. The injections are preferably given daily, the total number of injections to effect a cure being about 12 (2.7 to 4 gm.). In children the drug is given intramuscularly in buttocks in 25 per cent strength and the dose is according to weight; the maximum dose being for 60 pounds or more, adult dose; 50 pounds, 0.25 gm.; 40 pounds, 0.2 gm.; 30 pounds, 0.15 gm. and 20 pounds, 0.1 gm.

(3) *Urea stibamine*.—It has been very extensively used in India. It is slightly more toxic than neostibosan and is given intravenously in 5 to 10 per cent strength on alternate days. The initial dose is 0.05 gm. which is increased by 0.05 gm. at a time up to maximum of 0.2 gm.; total dose 2 to 2.9 gm. in 12 to 15 injections.

(4) *Solustibosan*.—Napier, Chaudhuri and Rai Chaudhuri first used the Bayer 561 preparation issued in ampoules of sterile isotonic solution ready for injection intramuscularly and also intravenously. The initial dose was 2 c.c. and then 4 c.c. and 6 c.c. repeating the last dose till a total of 60 c.c. was reached for every 100 pound body weight. *Stibatine* (Glaxo) is now used in much larger doses, viz, 20 c.c. intramuscularly for 10 consecutive days—a total of 200 c.c. A concentrated preparation is also available, the course consisting of 10 daily intramuscular injections of 4 c.c. each.

Course of the disease under treatment

The response to treatment is not immediate in most cases. With a potent drug like neostibosan, the temperature usually comes down after 5 or 6 injections; with tartar emetic it may take about double that number or even more.

In some patients the temperature persists throughout the course of treatment. The weight may decrease at first. But after a fortnight the patient improves steadily, the spleen diminishes in size, the weight increases and the hæmoglobin value rises. A rise of the white blood cells above 6,000 per c.mm. is an important sign of recovery. The liver is more slow to return to normal in size, a spleen which is already hard cannot be expected to be normal again until some time elapses. The Leishman-Donovan bodies sometimes persist even after the last injection but disappear subsequently.

In some cases progress is slow, but eventually a cure is obtained unless they happen to belong to the resistant group. Coincident infections such as malaria, dysentery and ankylostomiasis are suitably treated. Complications are common in kala-azar, of these perhaps the most dangerous is cancrum oris which should be treated energetically with antimony and penicillin, the latter being given intramuscularly in 10,000 to 20,000 units three hourly for one week, and locally in 500 units per c.c. for two to three weeks.

Napier thus summarizes the effect of treatment in uncomplicated cases. If a full course of neostibosan or urea stibamine is given between the third and twelfth month of the disease, 90 to 95 per cent are cured, about 2 per cent die of some intercurrent disease during the course of treatment, and the rest relapse. Of those that relapse, about half to two-thirds are cured by subsequent treatment, but there remains a small residue of entirely resistant cases. The prognosis is not so good when the disease has lasted more than a year. The above observations apply to Indian kala-azar only. In China and in some of the Mediterranean areas the disease is much more resistant, while in the Sudan the response to antimony treatment even after a prolonged course is very poor indeed.

Post-kala-azar dermal leishmaniasis

This is a sequel to generalized leishmania infection, the dermal lesions appearing from one to two years after all signs of visceral disease have disappeared. The pentavalent compounds are not so effective as in visceral form of the disease, and in some cases better results are obtained with the trivalent compounds such as neoantimosan. The injections are given on alternate days. The nodular lesions respond better than hypopigmented ones. It may be necessary to repeat the course two or more times.

When the nodules are few, a 2 per cent solution of berberine sulphate may be locally injected; when very extensive, they become more susceptible to antimony if the patient is subjected to preliminary treatment with large doses of potassium iodide.

Resistant cases of kala-azar

The introduction of diamidino stilbine (stilbamidine) in recent years marks an advance in the treatment of kala-azar, but as it is liable to produce serious toxic effects, it should be reserved, in India at least, for antimony-resistant cases only. Though it does not contain any antimony, some details about it are recorded here.

The drug is a white powder, supplied in ampoules and is administered intravenously after being dissolved in 10 c.c. of distilled water (1 per cent solution). If exposed to light, the solution develops a toxic product, so it must be prepared just before the injection which is given very

slowly and on successive days. The initial dose is 0.025 gm. which is increased by 0.010 or 0.020 gm. according to reaction till a maximum of 1 milligramme per pound weight of patient is reached. If there is reaction after an injection the next dose is preceded by an injection of 0.25 c.c. of 1 in 1,000 adrenaline. In children who tolerate the drug better than adults, the first dose is 0.010 gm. increased by 0.005 gm. to a little over 1 milligramme per pound body weight.

After an injection of stilbamidine the patient becomes flushed with a burning sensation in chest and abdomen, and in severe cases there is intense headache with giddiness and sometimes vomiting and considerable fall in blood pressure; there may be even unconsciousness. These effects can be controlled by adrenaline injections. Some patients develop trigeminal neuropathy as a sequel to this therapy. Commonly three or four months after the completion of treatment the patient notices loss of sensation over his face, complaining, for instance, that he cannot feel a cigarette in his lips. Paræsthesia may follow.

No improvement usually takes place in the patient during the actual course of treatment; indeed, at first, it may cause exacerbation of the symptoms, but soon after the last injection the temperature falls to normal, the spleen decreases in size and the patient begins to put on weight. The drug has no effect on other forms of leishmaniasis.

As an alternative to stilbamidine, it is recommended to give in resistant cases three courses of neostibosan, each of twelve daily injections, at intervals of 12 days. The initial dose is 0.2 gm. which is increased by 0.1 gm. up to a maximum of 0.5 gm. daily; in the second and third courses the initial doses should be 0.3 gm. Instead of giving neostibosan alone, it may be given in combination with urea stibamine. If the former is not available urea stibamine or aminostiburia is used in usual doses. If there is little or no improvement after the first course, it is advisable to give during the second course one or two intravenous injections of T.A.B. vaccine or a few intramuscular injections of milk.

Assessment of cure

Of the laboratory tests culture of the blood or the material from spleen or sternum puncture is the most reliable method, but it is a slow method, and is possible only in a well-equipped hospital. Microscopic examination of the smears after the puncture is the next best way of ascertaining whether parasites have disappeared from the system, but it has its limitations. The aldehyde reaction is not of much value, as, though it becomes less evident, it persists three or four months after the patient has, to all external appearances, completely recovered.

The best evidence of cure is the absence of all symptoms of the disease during at least six

months following the course of treatment. 'The complete cessation of fever and its continued absence for a considerable time is of value if accompanied by a substantial gain in weight approaching nearly to the normal; disappearance of the spleen beneath the costal margin in cases in which it had not been enlarged much below the navel when treatment was commenced, or reduction by several inches when the organ was well below the level of the navel; and the disappearance of the leucopenia with increase of the total leucocytes to the normal number or more, a slight degree of leucocytosis being often seen in favourable cases' (Rogers).

2. *Oriental sore (cutaneous leishmaniasis).*—This is caused by local infection of the skin by *Leishmania tropica*, an organism similar to *L. donovani*, but antimony is not very satisfactory in this condition, the progress being very slow. A course of neostibosan or neostam is given commencing with 0.1 gm. and increasing on alternate days to 0.3 to 0.4 gm. Twelve injections are usually necessary. Urea stibamine may also be used as an alternative in usual doses. Trivalent compounds usually act better and of these foudadin (neoantimosan) or anthiomalin is recommended. About 10 intramuscular injections on alternate days are usually sufficient, the initial dose being 1.5 c.c. and the maximum dose 5 c.c. If there are single or a few early sores without ulceration local treatment with berberine sulphate (orisol) is recommended. One c.c. of a 2 per cent solution is injected at four or more points into the indurated area surrounding the ulcer. The injections are given only once a week, though 2 or 3 sores can be dealt with at one sitting. Three to six treatments are necessary to effect a cure. Emetine hydrochloride has also been reported to be effective in producing healing, 20 minims of a 5 per cent solution being injected into the thickened edges and bases of the ulcers. A 2 per cent solution of neostam has also been similarly used. These local injections are suitable only when a few lesions are present. They cause some local inflammation and should not be given for sores on the face. There are many other methods of treatment and actually a judicious combination will be found to give better results. In obstinate cases x-rays are sometimes useful. *Leishmania* vaccine (autogens or stock) is under trial and good results have been reported in some cases.

3. *American or muco-cutaneous leishmaniasis (espundia).*—The disease is almost entirely confined to Central and South America and is caused by *Leishmania brasiliensis* which is morphologically indistinguishable from *L. donovani* and *L. tropica*.

It was in this form of leishmaniasis that antimony was first used in 1911. In the place of antimonyl tartrates, the new compounds, e.g. neostibosan, foudadin, are now being used with satisfactory results. Besides, local cauterization has also been practised.

150 years old...

1947 marks the 150th anniversary of Howards of Ilford, manufacturers of fine chemicals. Latterly, as most of our friends know, supplies have not been so freely available as they, or we would have wished, although conditions are improving. We would like to assure our friends, that we are doing our utmost to let our agents have everything we can spare, and that they, in turn, try to make the fairest possible distribution of what they get.

VIROL

in the treatment of debility

The composition of Virol is such that it satisfies all the most important dietetic requirements in the treatment of debility, whether the debility is due to illness or to other causes.

Virol provides an ample calorific intake of carbohydrates, protein, and fat, accompanied by an adequate supply of the other essential nutritive factors. It is readily assimilated and completely absorbed by even the most delicate digestive system, without risk of strain. Virol is pleasant in

flavour. The patient takes it with relish and benefits not only by its direct nutriment, but also because it assists in the digestion of other foods.

The value of Virol in debility and wasting conditions has been demonstrated by over forty years' clinical experience and by its increasing use in Hospitals and Clinics.

VIROL is composed of MALT EXTRACT, ANIMAL FATS (specially refined), EGGS, SUGARS (including Glucose), ORANGE JUICE and added mineral salts and vitamins

Agents for India: Messrs. A. H. Wheeler & Co., Asian Buildings, Nicol Road, Ballard Estate, Bombay

MULTIVITE

Trade Mark

Presenting Vitamins A B₁ C and D in a single pellet

The most satisfactory results are obtained when the vitamins are administered in a group. The rational explanation for this is based upon the following facts:—

1. Uncomplicated deficiencies of a single vitamin are rare.
2. The effects of incorrect proportions of vitamins taken are second only in seriousness to those of marked deficiencies.
3. Efficient utilisation of individual vitamins is in many cases dependent upon the presence of other vitamins in adequate amounts.

Multivite pellets are the original preparation in which fat-soluble and water-soluble vitamins are combined in one compact palatable product. They constitute an acceptable means of supplementing the vitamin intake from the diet and of preventing the appearance of deficiency symptoms of the four principal vitamins, A B₁ C and D.

Stocks of Multivite are held by leading chemists and full particulars are obtainable from—

AUGUST

THE BLOOD TRANSFUSION SERVICE AND BLOOD BANKS IN INDIA

For the purpose of supplying suitable donors of blood for special cases in hospitals and nursing homes a blood transfusion service was commenced in Calcutta 23 years ago. Later, this service was enlarged. Later still a blood bank was opened. During World War II a serum bank for freeze-drying serum was added at a special cost for the needs of the armed forces. Similar institutions were established at Bombay, Madras, Lucknow, Patna, Lahore and Shillong. For the needs of the civil population elsewhere in India the arrangements obtaining in Calcutta prior to the serum bank will be described and the present-day requirements added.

The beginning.—A service of supplying donors of blood, after grouping and matching directly the bloods of the prospective donors and recipients, was started by Lieut.-Colonel R. B. Lloyd, the then Imperial Serologist, in his laboratory in Calcutta in 1924 (Greval, 1937). This was the first blood transfusion service in India. It was meant for a small number of patients. The donors were recruited from the European and Anglo-Indian communities only and the fee was rather high for those days (Rs. 50). A register of donors was maintained and a record of physical, serological and hæmatological examination before and after each service was kept.

The enlargement.—Lieut.-Colonel S. D. S. Greval (then Major) who followed Lieut.-Colonel Lloyd enlarged the service in 1935 by recruiting Indian donors as well. The fee then could be reduced in deserving cases. Further, donors of all blood groups could be selected more easily.

Easy availability of blood steadily increased the demand for blood in Calcutta. A still further enlargement was then effected in 1939 with a view to meeting this demand and making provision for national emergencies as well. The usual register and records were maintained and it is worthy of record that during seven years, 1934-41, no donor suffered in health due to donation of blood. This service supplied donors for 366 transfusions in 1940. The population served was of the order of two million.

The blood bank.—This service was started in 1939 by Lieut.-Colonel S. D. S. Greval to supplement the service of donors of blood. The total number of persons, in addition to the members of the Imperial Serologist's staff, who took part in the organization of the bank was 16. Out of them only three were whole-time workers paid

from a fund raised by the Bengal Red Cross Society. Total salaries were of the order of Rs. 1,700 a year. Total cost of the equipment was Rs. 1,100, recurring expenditure being Rs. 200 (Greval, 1939, 1940a, 1941; Greval and Chandra, 1941). This was the first blood bank in India.

Relations' or friends' blood found incompatible in grouping for one prospective recipient was taken in a bottle, kept in a refrigerator and given to another recipient of the same group. The latter's relations' or friends' blood was also taken and, if found compatible, given to the first prospective recipient. Whenever possible, for one blood supplied two bloods were taken as some bloods were discarded due to a positive or doubtful Wassermann reaction.

Later, public-spirited free donors were persuaded to call every six weeks or so to part with 400-500 c.c. of blood. They were put on a register and could be sent for specially, if necessary. Now three months is considered to be a safer interval.

New professional paid donors of the donors' service (who were sent to give blood on the spot in hospitals and nursing homes) also gave a bottle of blood free to the bank. This constituted a test of suitability as donors.

[Some donors are known to collapse after giving varying quantities of blood. For their benefit (i) ampoules of adrenaline chloride, 1 in 1,000, (ii) aromatic spirit of ammonia, and (iii) lemonade should be at hand.]

Blood was also bought from prisons (for a nominal fee of Rs. 5 plus rest for 2 days plus a remission in sentence).

Hæmatological observations were made on all bloods collected. Two facts used special mention: (1) Some donors' citrated blood did not show any visible change after several weeks' storage. This was observed repeatedly. (2) On the whole the specific gravity of the blood from the prisons was higher than that of the blood of the same community outside. This could only be accounted for by the balance in diet, rigidly attended to in prisons.

The blood was stored for not more than ten days in the beginning and for not more than seven days later. Mostly it was used within 3 days. It was stored by (i) communities and (ii) unlike the then London blood banks, by groups. Universal 'donors' bloods of two qualities depending on the titre of the iso(hæmagglutinin) and with a limit of 300 c.c. for the second quality were also available. They were kept in distinctive containers and could be issued at a moment's notice.

In the middle of 1941 about 200 donors of all classes could be bled for a national emergency every six weeks.

The plasma bank.—From blood remaining in storage longer than seven days plasma was separated and made safe for transfusion (*vide infra*).

The serum bank.—This was essentially a war-time establishment and would be rather a wasteful way of providing material for transfusion in peace time. Bloods were taken and allowed to clot. Clear sera were pooled, filtered and freeze-dried by special machinery.

The plasma, a by-product in a blood bank, can be dried like serum also and waste avoided.

The war-time dried serum stocks are still available in most countries. They are not likely to be replaced when expended.

Rhesus grouping.—The double blood transfusion service of pre-war Calcutta (donors, and bottled blood and plasma) can be easily established in all big towns in India where laboratory facilities exist. All the donors now, however, should also be rhesus-grouped. Most of the reactions due to the Rh incompatibility are due to the presence or absence of the antigen Rh₀ which can be detected by an animal serum (Grevall and Roy Chowdhury, 1946). Human testing sera so far have not been collected in India. American sera (kindly supplied by Dr. Wiener) have been used for special cases for several years in the Imperial Serologist's Laboratory, Calcutta.

If possible, Rh— subjects (by animal serum) should not be given whole blood at all, lest some rbc negative by the animal serum should be positive by human serum (*i.e.* contain Rh' and Rh" antigen). All Rh— subjects who have had a previous blood transfusion and all Rh— females who have borne children should have special attention paid to cross-matching test: the action of their sera on the rbc of the donor should be studied in a conglutination test after at least one hour's incubation. A prospective recipient Rh— by animal serum should, of course, never receive blood from a prospective donor Rh+ by animal serum.

(If human testing sera against Rh' and Rh" are available the correct sub-type can, of course, be determined and a whole blood transfusion given.)

Further, all \pm , doubtful, reactions by animal serum should be looked upon as negative in a recipient and as positive in a donor.

A subject ORh— (negative with human sera as well) with low isonin content has been considered safe all round. Such, however, is not the case. The donor may isoimmunize an Hr negative subject. The same observation applies to Rh— subjects of other groups for these groups. An Rh— donor should only be used for an Rh— recipient unless, of course, the exact type can be determined and the Hr incompatibility ruled out.

It has been suspected that there is a boost in blood transfusion (Albrecht, 1946). The boost should be discouraged. The plasma (subject to the restriction under the new danger of homologous serum jaundice) or serum (reconstituted from freeze-dried material) suffices in most cases.

Homologous serum jaundice.—The new danger of homologous serum jaundice (Editorial, 1947) introduces a risk in plasma transfusion like the risk of Rh incompatibility in whole blood transfusion. The risk really is greater inasmuch as it cannot be foretold. All donors with a history of jaundice must, of course, be excluded.

Probably protein hydrolysates will ultimately be found to be more suitable for intravenous alimentation than blood, serum or plasma.

When the rbc must be used, it should be possible to remove all traces of plasma from them (Editorial, *loc. cit.*).

Points in procedure: (1) *Collection of blood.*—A Potain's aspirator available in most hospitals in India suffices for an apparatus. The stopper carrying the essential parts fits an ordinary bottle quite well. In the bottle are sterilized as many c.c. of a 3 per cent solution of sodium citrate as multiplied by 10 give the total quantity of blood taken in the bottle (20 c.c. for 200, 30 for 300 and so on). Details were published in this journal (Grevall and Chandra, 1940). This method was redescribed later by other workers (Napier and Das Gupta, 1941; 1945). Recently a 2.0 to 2.5 per cent solution of disodium hydrogen citrate has been preferred. It does not char glucose if the latter is to be added for the preservation of the red blood cells (disodium hydrogen citrate 2.0 to 2.5 per cent 100 c.c. plus glucose 15 per cent 20 c.c., total 120 c.c., which is sufficient to prevent clotting in 400 to 420 c.c. of blood) and a slightly acid reaction of the mixture further aids the preservation (Maycock, 1947).

(2) *Preservation.*—The special stopper of the apparatus is replaced by an ordinary glass stopper with sterile precaution and the bottle after inscription (with Indian ink, covered with a layer of collodion) is left at room temperature to complete half an hour of this temperature. The blood left in the tube is preserved in two lots: (i) in sodium citrate solution for the red blood cells and (ii) in a dry tube for serum, for cross-matching the recipient. All the containers of blood are left in a refrigerator (one free from vibrations—electrolux—preferred) at about 4 to 8°C., the usual temperature outside the freezing chamber.

Blood preserved for less than a week is as useful as fresh blood, for most purposes (Grevall *et al.*, 1940). After a week its plasma should be collected and stored as a liquid up to 18 to 24 months or as a freeze-dried powder for at least 5 years (Maycock, *loc. cit.*). Preservation of the red blood corpuscles for longer periods, with the aid of glucose, is really not necessary for banking blood, although the method is used for keeping blood for experimental purposes and for the manufacture of anti-sera against certain hæmagglutinogens. Recently this method has been described again (Khanolkar, 1946).

Pooling of plasma from several donors of different groups makes it safe by lowering its isonin content. On the other hand, the virus of homologous serum jaundice is thus spread over a larger number of recipients. A mixture of two bottles from subjects A and B will yield a safe plasma as a rule (Greval, 1940b).

Medical News

SCIENCE TO-DAY

THIS weekly publication is published by the Weekly Science Newsletter Ltd., 104, Clifton Hill, London, N.W.8. Its aim is to provide weekly a brief, but accurate, survey of contemporary advances in all branches of science. A. W. Haslett, M.A., is the editor. Subscription rates are 10s. a year (50 issues) or 5s. 6d for six months (25 issues).

Subjects which have so far been covered include the following:—

- New law of magnetism.
- Thorium and atomic energy.
- Research uses of rockets.
- Electronic calculators.
- Artificial rain.
- Cosmic radiation.
- Growth-control in plants.
- The chemistry of bacteria.
- Thirty million volt x-rays.
- Radioactivity and research.
- The structure of protein.
- Air navigation progress.
- Locust control.
- New chemical elements.
- Antarctic exploration.
- Future of radar techniques.
- Mountain building.
- Reflecting microscopes.

The 19th June, 1947, issue contains the following items: mountain building, the new radioactivity, Prof. Evans's visit in brief, strength of materials, books.

INTERNATIONAL SHORT WAVE CONGRESS, AMSTERDAM

19TH TO 24TH JULY, 1948

Direction:

DR. W. BEAUMONT, London. Dr. A. Gjertz, Stockholm. Prof. Dr. C. Guarini, Naples. Prof. Dr. D. Kobak, Chicago. Prof. Dr. W. Kowarschik, Vienna. Dr. P. Liebesny, New York.

Dr. J. Meyer, Paris. Dr. L. Rósa, Budapest. Dr. J. Saidman, Paris. Dr. J. Samuels, Amsterdam. Prof. Dr. F. Scheminzy, Innsbruck. Prof. Dr. E. Schliephake, Würzburg.

Colleagues, if possible also biologists and physicists, are requested to give their names for holding lectures. A difference will be made between important communications, for which 20 to 30 minutes are allowed, and less important ones for which 5 to 10 minutes' time can be given. Those who will hold a lecture must also send their manuscripts to the main secretary's office, Weteringschans 73, Amsterdam, before the 15th April, 1948, at the latest, so that it can be taken up in the congress report.

PUNJAB MEDICAL COUNCIL

PROCEEDINGS of a meeting of the Punjab Medical Council held in the Committee Room of the office of the Director of Public Health, Punjab, Lahore, on Saturday, the 26th April, 1947, at 10 a.m.

Present

1. Lieut.-Colonel B. S. Nat, M.D., F.R.C.S., I.M.S., President.

Members

2. Dr. Abdul Hakim Khan, M.B., B.S.
3. Lieut.-Colonel Amir Chand, F.R.C.P.E., I.M.S. (Retd.).
4. Dr. Bikrama Jit Sahni, L.R.C.P. & S., D.P.H.
5. Dr. Kewal Ram Chaudhri, F.R.C.S.
6. Rai Bahadur Dr. Maharaj Krishna Kapur, C.B.E., L.M.S., D.P.H.
7. Lieut.-Colonel S. M. K. Mallick, M.R.C.P., D.P.H., I.M.S.
8. Rai Bahadur Dr. Mathra Dass, P.C.M.S. (Retd.).
9. Dr. Ch. Mohd. Nawaz, M.D. (Munich).
10. Captain Ram Chand Goulatia, M.B., B.S.
11. Khan Bahadur Dr. M. Yacob, D.P.H.
12. Lieut.-Colonel A. Sargood Fry, C.B.E., I.M.S.

Before transacting the business the following resolution moved by the President was carried all standing:—

(i) That this meeting of the Punjab Medical Council places on record their deep sense of grief on the sad demise of Khan Bahadur Dr. K. A. Rahman who was associated with this Council as a member for about 24 years.

(ii) That a copy of this resolution be forwarded to the members of the deceased family.

1. The proceedings of the last meeting held on the 30th November, 1946, were confirmed.

2. Election of the Vice-President.

Dr. K. R. Chaudhri proposed and Dr. Ch. Mohd. Nawaz seconded that Captain Ram Chand Goulatia be elected as Vice-President of the Punjab Medical Council.

Though there was no other proposal a ballot was taken as required under the rules and as all the votes were in the affirmative Captain Ram Chand was declared unanimously elected as Vice-President of the Punjab Medical Council.

3. Election of members on the Executive Committee.

Dr. K. R. Chaudhri proposed and Captain Ram Chand Goulatia seconded that Dr. Ch. Mohd. Nawaz be elected as a member of the Executive Committee.

Lieut.-Colonel Mallick proposed and Khan Bahadur Dr. M. Yacob seconded that Dr. Vishwa Nath be elected as a member of the Executive Committee.

As there was no other proposal Dr. Ch. Mohd. Nawaz and Dr. Vishwa Nath were declared elected to the Executive Committee.

4. Election of a representative of the Punjab Medical Council on the Governing Body of the Punjab State Medical Faculty.

Dr. B. J. Sahni proposed and Dr. K. R. Chaudhri seconded that Lieut.-Colonel Amir Chand be elected as a representative of the Punjab Medical Council on the Governing Body of the Punjab State Medical Faculty.

Lieut.-Colonel Mallick proposed and Lieut.-Colonel A. Sargood Fry seconded that Dr. Vishwa Nath be elected as a representative of the Punjab Medical Council on the Governing Body of the Punjab State Medical Faculty.

In favour of the proposal of Dr. B. J. Sahni, 6.

In favour of the proposal of Lieut.-Colonel Mallick, 5.

Lieut.-Colonel Amir Chand was declared elected as a representative of the Punjab Medical Council on the Governing Body of the Punjab State Medical Faculty.

5. Considered the case of Dr. Ahmad Sadiq, M.B., B.S., for the grant of a yellow fever inoculation certificate. In this connection considered the request of Dr. Ahmad Sadiq for postponing the consideration of his case.

Resolved that the case of Dr. Ahmad Sadiq be postponed for consideration at the next meeting of the Punjab Medical Council.

6. Considered the case of Dr. Kirpa Ram Sud, M.B., B.S., Simla, for advertising, and in this connection also considered the request of Dr. Kirpa Ram Sud for postponing the consideration of his case.

Resolved that the case of Dr. Kirpa Ram Sud be postponed for consideration at the next meeting of the Punjab Medical Council.

7. Considered letter no. 8898-M-46/1838, dated the 23rd January, 1947, from the Punjab Government, re. amendment of rule 46.

Resolved that the Council approves the amendment suggested by Government.

8. Considered letter no. HCM2883/47, dated the 22nd January, 1947, from the Registrar, Madras Medical Council, re. composition of the Medical Council of India.

Resolved that the Central Government be requested to suitably amend the Indian Medical Council Act so as to make provision for an elected representative of each of the Provincial Medical Councils in India to serve on the Medical Council of India.

9. Considered the recommendations of the Executive Committee held on the 12th April, 1947 (already circulated).

Resolved that the recommendations of the Executive Committee at items nos. 1 to 3, 5 to 7 and 9 be approved.

Item no. 4. Resolved that a reference be made to the General Medical Council that Dr. B. S. Jain, who held the triple qualifications of L.R.C.P. & S. (Edin.) and L.R.F.P. & S. (Glasgow), and who was deprived of the qualifications of L.R.F.P. & S. (Glasgow) on account of his name having been removed from the Register of the General Medical Council, is still entitled to be registered in the Register of the General Medical Council with the qualifications of L.R.C.P. & S. (Edin.) in case the General Medical Council decides to restore his name.

(ii) That the date on which he was deprived of the qualification of L.R.F.P. & S. (Glasgow) be ascertained from the Secretary of the Royal Faculty of Physicians and Surgeons (Glasgow).

Item no. 8. Resolved that Dr. Chanan Singh Mann be informed that in view of his past conduct the Council is not prepared to restore his name to the Punjab Medical Register.

10. Punjab Government letter no. 1812-M-47/8738, dated the 9th April, 1947, regarding the amendment of the Punjab Medical Registration Act was read and recorded.

11. Considered the statement of income and expenditure for the year 1946.

Resolved that the statement of income and expenditure for the year 1946 be approved.

Sd./- HANS RAJ,
Registrar,
Punjab Medical Council.

Sd./- B. S. NAT,
LIEUTENANT-COLONEL, I.M.S.,
President,
Punjab Medical Council.

STREPTOMYCIN

(Abstracted from a letter dated 22nd March, 1947, from the London correspondent to the J.A.M.A., published in the 10th May, 1947, issue, p. 204)

AMERICAN reports have raised high hopes of the value of streptomycin. The Ministry of Health has issued a warning on the subject, stating that trials are being carried out by the Medical Research Council, and until these have been completed it is not possible to assess the value of the drug and to determine the best methods of use. The latest American reports are regarded as indicating that the value of streptomycin in tuberculosis is still unproved. While the Minister of Health does not wish to hamper doctors and hospitals in their endeavours to obtain new drugs which may benefit their patients, he emphasizes that streptomycin is potentially dangerous and may cause ill effects such as giddiness and deafness. Insufficient is known about the drug at present to justify the government in making it more freely available. For instance, in a very small number of patients with tuberculous meningitis whose life has been prolonged by the treatment there has nearly always been permanent serious mental derangement, blindness or deafness.

CAMPAIGN AGAINST TUBERCULOSIS IN AUSTRALIA

According to a 'Medical Memoranda' item in the *British Medical Journal*, 31st May, 1947, page 765, the Australian Government has started a campaign against tuberculosis and appointed Dr. Harry Wenderly as Director of Tuberculosis. The Commonwealth Government has granted £250,000 for payment to sufferers from the disease and their dependants.

YOU CAN . . . RAISE BABY BY MAIL IN AUSTRALIA

By BOYD DAVIES

(Reproduced from Release No. P/639, offered by the Public Relations Officer, Australian High Commissioner's Office, New Delhi)

In addition to correspondence schools conducted by State Departments of Education to give education to 'outback' children, Australia has pioneered the mails as a means of bringing scientific care and health to many isolated children in their first crucial years.

By this correspondence system, many Australian mothers, miles from the nearest doctor, are successfully rearing their babies. The scheme applies mainly to South Australia, and this is one of the reasons given for the State's low infant mortality rate.

For the year ended December 1946, only 27.07 babies in every 1,000 born there did not live to one year. This was not only the lowest infant death rate of anywhere in the Commonwealth of Australia (except the sparsely settled Northern Territory), but was lower than that of any sovereign State in the world. The 1944 figure for the State was 29.07.

1,700 'Subscribers'

Behind the novel 'Mail Baby' project is the Mothers' and Babies' Health Association of South

Australia, which now supplies regular written lectures to mothers in the State and to isolated areas throughout Australia's 3,000,000 square miles.

Mothers in Western Australia, Darwin, New Guinea and on solitary lighthouses are among the 1,700 who are bringing up 'Mail' babies.

For these isolated women, help takes the form of 'lectures', including instructions on the correct diet and exercise for mother and baby, general health problems, childhood ailments, and hints on suitable baby clothing. These hints, doctors say, have helped many a baby safely through the first and second years.

Sister Nora Godlee, who is in charge of the correspondence section of the Mothers' and Babies' Health Association, studies the case of each child individually, and applies her intimate knowledge of early childhood problems.

Service by Train

If mothers live in small country towns, trained sisters of the M.B.H.A. offer advice personally, and watch the health of growing babies during regular periodical visits.

Country towns over a wide area of South Australia have their own clinics and there are 161 in all, but to assist even the most isolated mother the M.B.H.A. runs two special trains, staffed by double- and triple-certificated sisters. The schedule of these trains is advertised in all country newspapers and broadcast over all metropolitan and provincial radio stations. The trains, drawn free by the South Australian Railways, are sidetracked at selected spots for several days, until all mothers within a radius of 50 miles have had an opportunity of receiving the free advice offered by the train staff.

Pre-natal Care

The work of this Government-subsidized organization does not lie solely in post-natal care, but also caters for the expectant mother.

Whenever possible the mother-to-be receives highly specialized pre-natal care at any of the dozens of hospitals in South Australia or from her own family doctor.

A specialist at South Australia's largest maternity hospital (the Queen Victoria) said recently that although South Australia's infant mortality rate stood at 180 in the thousand in 1875, little was done about scientifically reducing the loss until 1920.

At the end of the last century babies were often born in the mother's home, and if facilities were lacking or birth was difficult, the lives of both mother and infant were endangered.

Sometimes in poorer areas babies are still born in the home, with the doctor called in at the last moment. But in the overwhelming majority of cases doctors study each expectant mother months before the baby is due, and order a hospital confinement.

In the normal course of events, the expectant mother reports to the hospital five months before the baby is due and receives instructions about correct diet and general hygiene.

Any abnormalities are determined by x-rays, and doctors examine the woman to see if she has tuberculosis, a heart disease or anything which could be passed on to the baby.

If what the doctors call the incompatible Rh factor—a blood condition—is present, deaths are reduced by a blood transfusion given to the baby immediately after its birth.

Although safe painless birth for all is still far off in Australia as elsewhere, the latest sedatives are used and play their part in reducing shock and worry to the mother and giving baby a better chance of a normal birth.

Glassed-in nurseries minimize the risk of infection after birth, and babies are handled as little as possible.

Washing Reduced

It was recently found that the risk of infection to newly-born babies was cut by giving them fewer baths, and in many Australian hospitals doctors avoid the

risk of infecting the youngsters by ordering only two baths—one immediately after birth and the other just before the mother leaves hospital to take her baby home. Babies are cleaned with frequent oil spongings.

Doctors point out that premature births will probably always lead to some deaths among babies, and that no country is likely ever to have an infant death rate of nil. But this is no discouragement to the struggle by Australians to get 'as near to nil as possible'.

TEMPORARY SURGICAL CAMPS

It is notified for information of medical practitioners that the attention of this Council has been drawn to the inadequacy of after-care arrangements at Temporary Surgical Camps organized by medical men and they are requested to note that any negligence in this respect will be taken serious notice of by this Council.

By order

Registrar,
Bombay Medical Council.

YELLOW FEVER VACCINE INJECTIONS

MEDICAL practitioners are reminded of the orders of the Government of India, viz, that yellow fever vaccine is available only at Government institutions and they are therefore advised that it is improper for medical practitioners to give injections against yellow fever even though vaccine may be supplied by their patients, as it is very likely that such vaccine is either 'not genuine' or 'is such as has fallen into wrong hands'.

Registrar,
Bombay Medical Council.

K. R. K. IYENGAR, M.B.E., C.I.E., M.D. (Edin.),
D.P.H. (Lond.)

LIEUTENANT-COLONEL, I.M.S. (Retd.)

LIEUT.-COLONEL IYENGAR passed away after prolonged illness at his residence 'Shelwood' on the midnight of Sunday, 20th July, 1947, at the age of 65.

Colonel Iyengar was born in 1883. He was educated at the Central College, Bangalore, and at the University of Edinburgh where he obtained M.B., Ch.B. in 1908 and M.D. with Honours in 1926. He also obtained the D.P.H. (Lond.) in 1910.

Colonel Iyengar was in the Mysore State Medical Service from 1911 to 1914. He joined the Medical Research Department and worked at the Central Research Institute, Kasauli, from 1914 to 1928 except for two years 1924-1926 when he was on military duty. He joined the I.M.S. in 1921. He was appointed Director, Pasteur Institute of Southern India, Coonoor, in 1928 in which post he continued till his retirement in 1938. He held the post again from 1941 to 1946.

His contributions to science include 26 publications on the Wassermann reaction and its results in malaria, tuberculosis, kala-azar, etc., on problems in immunization with vaccines and on rabies. He was elected president of the Medical and Veterinary Section of the Indian Science Congress in 1935 and his address to the congress was on 'Rabies'.

Colonel Iyengar was awarded the Research Worker's medal and the honour of O.B.E. in 1939 and C.I.E. in 1945.

He was the founder-president of the Nilgiris Rotary Club 1942 and was elected District Governor of the South India Rotary Clubs in 1943; also president of the Coonoor Club and Freemason—Worshipful Master of the Anchor of Hope Lodge, Wellington. He carried on vigorous war propaganda as president of the District War Propaganda Committee from 1939 to 1945. He was a very keen horticulturist and has made the Coonoor Pasteur Institute Gardens one of the finest in the Nilgiris.

Colonel Iyengar leaves behind him his wife Usha Iyengar, the second daughter of late Lieut.-Colonel N. P. Sinha, r.m.s., elder brother of the first Lord Sinha, three daughters and two sons, and a very large circle of relatives and friends to bemoan his loss.

OBSERVATIONS ON ANÆMIA IN THE MALNAD PARTS OF THE MYSORE STATE

By N. A. AIENGAR, L.R.C.P., M.R.C.S.

District Medical Officer

B. R. LAXMINARASIMHALU NAIDU, L.M.P.

Pathologist

C. B. KRISHNAMURTHY, L.M.P.

Radiologist

and

B. RANGANNA, L.M.P.

House Physician

McGann Hospital, Shimoga (Mysore State)

THE State of Mysore is divided roughly into two areas—the Malnad and the Maidan. The former comprises of parts of the districts of Shimoga, Kadur, Hassan and Mysore. The so-called Malnad area skirts the Western Ghats all along, studded with well-wooded evergreen forests; the rainfall ranges from 35 inches to an average of 360 inches. Last year, i.e. 1946, one of the places recorded 580 inches. This paper is based mainly on the observations made in the Shimoga district and its neighbouring taluks of Kadur district and part of Hassan district. The conditions in a similar area of the Mysore district are said to be very much better than in any other district and so nothing is said of that area. The first observation by one of the authors (N. A. A.) was made in the years 1940 and 1941, when he was stationed at Hassan. Cases of extreme anæmia with enlargements of spleen complicated with ankylostomiasis were noticed taking resort to the hospital. At that time not much enquiry was made into the causation of this condition beyond considering the curing of the patients. The two taluks, Belur and Saklespur, of Hassan district in addition to having well-wooded hills and valleys have plantations of coffee, orange, cardamom and paddy fields. In Kadur district too the conditions are alike; whereas in Shimoga district one finds more of areca-nut gardens and paddy fields. The ghat area rises up to 5,000 feet and there are deep valleys in between. During the monsoon weather plenty of hill-streams and torrents rapidly flow along, dividing and cutting off villages from external contact. During summer there is not a drop of water in many places. The rainy weather lasts from the middle of June till the middle of October. Roads are few and are of a very primitive character, with the exception of the provincial roads and a few fairweather District Board roads. It is bad enough during summer to transport either people or material; it is impossible in the rainy weather; some places become temporary islands for 3 months in the

year. Since the year 1943 up till now on an average 500 cases of anæmia of an extreme degree have come for treatment to the McGann Hospital, Shimoga, every year. This constant flow of these cases every day attracted our attention. Whatever the cases were, whether acute, chronic, surgical or medical, they were complicated with ankylostomiasis which made the recovery difficult. Owing to conditions of war that existed in the major part of these years for want of sufficient staff and equipment very many details could not be worked out; besides, the extremely poor condition of the patients made it practically impossible to carry out all the necessary investigations. Anything was a torture and anything might kill them. This year the investigations were carried on in a better fashion in 50 cases. As a routine in all the 2,000 cases blood counts were made, percentages of hæmoglobin calculated, and the stools and blood were examined for parasites. Amongst women patients pregnancy added to the complication and made it worse. At one time it was thought that transfusion of blood might improve matters. To our disappointment it did not help much. During these trials it was a problem to get donors. Every second person that one could place one's finger on was anæmic and could not afford to lose any blood; and whenever a willing fit donor was found, these extremely anæmic bloods never matched. In one or two cases we persisted trying to find a suitable donor and patiently cross matched as many as 50 bloods and not one was compatible. Plasma also was tried but with disappointing results. It appears that their system is already water-logged and cannot tolerate any further fluid intake. It is not the quantity that one has got to think of in these cases, but it is the improvement of the quality. We have no facilities to transfuse concentrated R.B.Cs. As a next step we tried injecting blood intramuscularly. In some cases it did give a response to a certain degree; patients that were chalky white soon got a darker hue about them and gave a chance for further treatment with liver and iron. It is surprising to see people walk into the clinic with as low a blood count as $3\frac{1}{2}$ lakhs per c.mm. and hæmoglobin about 12 per cent. It is true they are beyond all chances of recovery; but yet they are alive. The table just gives an idea as to the blood counts, colour index and other details and also the percentage of low blood counts that were found in these 33 cases which will be a fair indication of the other cases.

General examination.—The patients are extremely ill, highly anæmic with hollow sunken pale eyes, puffed out cheeks and pot bellies. Their limbs are just like sticks hanging from

TABLE

The figures below show the total R.B.C. count of each of the 33 patients among men and women in the years 1945 and 1946

Total R.B.C. count in terms of millions

	Below 1		1 to 1		1 to 1½		1½ to 2		2 to 2½		2½ to 3		3 to 3½		3½ to 4		4 to 4½		4½ to 5		Above 5		Total
	Men	Women	Men	Women	Men	Women	Men	Women	Men	Women	Men	Women	Men	Women	Men	Women	Men	Women	Men	Women	Men	Women	
1945	3	..	25	51	20	56	33	29	19	28	34	27	20	28	18	18	18	24	22	10	8	1	492
1946	2	..	20	37	35	56	26	21	35	25	38	15	30	15	28	18	27	11	15	3	8	1	466

The above figures show that on an average 500 cases are admitted into this hospital for the treatment of anæmia.

The table below shows 33 cases worked out in the available details from the limited staff and materials.

TABLE—contd.

Case number	Age	Sex			Stools	Urine	Gastric analysis
1	23	F.	Pregnancy 7½ months, III para, spleen +.	R.B.C. 1.5, Hb. 20%, C.I. 0.7, B.P. normocytic hypochromic, W.B.C. 4,200, D.C. poly 52%, eosino 6%, lympho 40%, large mono 2%.	Ankylostoma ova +.	Normal	..
2	20	F.	Pregnancy 8 months, II para, spleen ++.	R.B.C. 0.86 million, Hb. 10%, C.I. 0.6, B.P. moderate anisocytosis, W.B.C. 2,600, poly 43%, eosino 7%, lympho 50%, no megaloblasts. Normocytes predominant.	Do.	Albumin ++.	..
3	24	F.	Pregnancy 7 months, V para, spleen +.	R.B.C. 0.92, Hb. 15%, C.I. 0.8, B.P. normocytic hypochromic, W.B.C. 3,000, D.C. poly 45%, eosino 6%, lympho 47%, large mono 2%.	Roundworm ova +.	Normal	..
4	50	M.	Fever since 3 months, spleen +++.	R.B.C. 2.48, Hb. 30, C.I. 0.6, B.P. normocytic hypochromic, W.B.C. 3,200, poly 35%, eosino 10%, large mono 5%, lympho 50%.	Roundworm ova, ankylostoma ova +.	Do.	Normal
5	23	M.	Dysentery and fever 6 months, spleen —.	R.B.C. 1.56, Hb. 35, C.I. 1.1, B.P. normoblasts, normocytes predominant. W.B.C. 5,700, poly 51%, eosino 7%, large mono 3%, lympho 39%.	Ankylostoma and roundworm ova +.	Do.	No free HCl in the fasting sample, rest normal.
6	30	M.	Fever 2 months, spleen +++.	R.B.C. 1.42, Hb. 25, C.I. 9, B.P. normocytic hypochromic, W.B.C. 4,400, poly 55%, eosino 6%, large mono 2%, lympho 37%.	Roundworm ova +.	Do.	Tendency for hyperchlorhydria.
7	20	F.	Pregnancy 7½ months, I para, general œdema.	R.B.C. 1.06, Hb. 15, C.I. 0.75, B.P. normocytic hypochromic, W.B.C. 12,400, poly 45%, eosino 7%, large mono 3%, lympho 45%.	No cyst. no ova.	Albumin +.	..
8	22	F.	Pregnancy 6½ months, II para, spleen +++.	R.B.C. 1.28, Hb. 15, C.I. 0.6, B.P. hypochromic microcytic anæmia, W.B.C. 2,800, poly 49%, lympho 32%, eosino 13%, large mono 6%.	Ankylostoma and roundworm ova +.	Normal	..
9	25	F.	Pregnancy 7 months, II para, spleen ++.	R.B.C. 1.32, Hb. 20, C.I. 0.8, B.P. hypochromic anæmia, W.B.C. 4,100, poly 50%, lympho 39%, eosino 9%, large mono 2%.	<i>E. histolytica</i> cyst +.	Do.	..

The above may be taken as examples of usual types of anæmia met with in these parts.

TABLE—contd.

Case number	Age	Sex			Stools	Urine	Gastric analysis

The above may be taken as examples of usual types of anæmia met with in these parts.

the body. They are short of breath and with some difficulty they do walk along into the clinic. In some there is general anasarca. In such cases the abdomen, the feet and the cheek are swollen up. The spleen is enlarged to a very great extent occupying almost the whole of the abdomen, including the pelvis even. The spleen takes different shapes, in some cases lengthens like a ploughshare (see plate XVII). The liver is enlarged in many cases. The heart invariably shows myocardial degeneration. The patients show certain amount of congestion of the lungs. The skin is dry—dermatitis, sores and ulcers are found. These ulcers start as small pimples on the lower extremities and before the

end of a week they occupy a large area. They are indolent, callous, pale and chronic; in some cases as old as a couple of years (see plate XVII).

Apart from malaria and helminthic infections, which are the causative factors, the extremely poor condition of these patients is, due to neglect on their part, due to economic reasons and ignorance.

Hæmatological findings.—From the above figures it is noted that 16 per cent of cases show a total R.B.C. count of less than one million. Between 1 to 1½ million the percentage works out at 15 per cent. The percentage of women is greater than that of men. Amongst women even anæmias of pregnancy are included.

The colour index in these low count cases is more often above one. The details are :—

1. *Size and shape of R.B.C.*—Most of these cases show a vacuolated normocyte. In some, microcytes and normoblasts are found. No megaloblasts were seen. All the cases showed a certain degree of anisocytosis but normoblasts were predominant.

2. *W.B.C.*—Between 2,400 to 6,000 per c.mm. is the usual count.

3. *Differential count.*—There is a slight increase in the eosinophils in most of the cases.

Stools.—Most cases show ankylostoma ova, roundworm ova and *Entamoeba histolytica* or cysts. Some specimens showed the presence of more than one type of helminthic infection. No *Tania* of any sort was noted.

Urine.—Only a few cases showed the presence of albumin.

Gastric analysis.—Owing to the extremely delicate conditions of the patients, the gastric juices of only 10 patients from the above list were examined. It is concluded that most of them showed either a normal hydrochloric acid content or showed a tendency for hyperchlorhydria. In no case hypochlorhydria was noticed.

Radiological findings.—Photographs of 4 cases are shown in plate XVII. Only a few cases, viz, eight, were examined, since the patients could not tolerate even a barium meal examination under fluoroscopy owing to tendency to vomiting. They could not take more than 4 oz. at a time. It is seen from the pictures that the stomachs are extraordinarily small and in all the 4 cases they are more or less tubular and spasmodic. They showed a tendency towards hyperactivity after release of the spasm. The spasm disappeared after a time in some.

Some 200 years ago in this very same area prospered a kingdom known as Bidanur. Bidanur, the capital city now known as Nagar after its conquest by Hyder Ali, had, it is said, a population of 5 lakhs. There were different nationalities : Chinese, Portuguese, French, English, Mahrattas, Mohammedans and the local Hindu population. Even now the ruins remain. This Nagar to-day has not a population of five hundred. It is a desolate dilapidated village. A scion of one of the ancient families is trying to bring it into some shape. This place is right at the head of the ghat with thick forests all round and the rainfall is about 200 inches per year. The villages round about are no more than little hamlets of one or two houses and a few thatched huts. In some villages one finds only a single house. The population is declining. In some villages comprising one house and its lands there are just two people and probably one of them may be ill. For a population of 5 lakhs in a town to exist with prosperous villages all round, there must have been some sort of a system in those days to render these places healthy. In the wake of

war and destruction the civilization that existed then dwindled; the system then was soon forgotten; the new methods of another civilization did not suit; desolation set in.

Nutrition.—The food of the average farm labourer is very poor; it is protein and fat-free. He just lives on rice boiled or made into a conjee; he does not know what dhal or milk is like. From childhood he has not tasted milk either human or otherwise. Women die either during pregnancy or during labour or soon after it. Maternal mortality is very high. For want of milk, children are brought upon rice conjee from early infancy. Most of them are vegetarians but they do not even consume vegetables. They may have a chilli or an onion. Even the non-vegetarians by virtue of necessity have become vegetarians. Beyond occasionally having some game or some meat when available, when a sheep is slaughtered once in a way, or some fish during season, they mainly live on rice or rice conjee. On the outskirts of the Malnad some Goulics rear herds of buffaloes in the forest. They do not sell milk or buttermilk. They just get the butter out and the rest is given back to the animals. As one goes interior, the cattle are miserable specimens. They are small in stature, as big as a full-grown sheep. Their yield is very poor; about a *pau* or less of milk per head is all that one can get and that during the rainy season when there is some jungle fodder available. During summer they feed on any refuse and even faecal matter. These cattle are maintained more for providing manure than milk.

Owing to disease and ill health the farmer does not start his day's work before 9 a.m. Within a couple of hours the sun is up and the day gets too hot. He gets his usual rigor and fever and for the rest of the day he is bed-ridden and useless; so, economically, he is a loss and a drag on the family and the country. His working capacity is reduced to a very low level. Nature is bountiful and kind to him. Without much labour he gets one crop annually : it is the rainy season crop. His methods of agriculture are primitive. In these parts one can manage to raise at least two crops in the year easily. Owing to depopulation labour is not available. What labour is available comes from the west coast during the seasons only. As a result much of the arable land is left fallow.

Treatment.—The usual treatment followed in these cases at this hospital is firstly attention to diet. Such of those as are meat-eaters are given a mixed diet consisting of eggs, bread, butter and coffee in the morning; meat curry and rice in the afternoon; and at night a vegetable curry and either chapatti or rice. In addition they also get two pints of milk per day. As for pure vegetarians egg is served in the shape of flip; bread, butter and coffee in the morning, vegetable curry and rice in the afternoon, and chapatti and vegetable curry in the night. They are also given two pints of milk

per day. The extremely bad cases have got to be fed very carefully since they develop diarrhoea if their full quota of diet is given. During seasons oranges are given free to all deserving poor patients.

As for medicines, they are put on injections of liver extract and a mixture consisting of ferri-et-ammon citras, quinine sulph, acid hydrochlor dil, liquor arsenicalis and aqua. Nicotinic acid or yeast tablets are administered daily as a routine. The deworming operations are started with care. They are undertaken only when the patients get to a fairly tolerable condition when they can put up with a purgative. The skin is attended to for any dermatitis and the ulcers, if any, are cleaned up. As their general condition improves, automatically the ulcers heal without any further treatment. Whenever possible the foot of the bed is raised. It is observed during the course of treatment that many of these cases show some improvement till they reach a level of 2.5 to 3 million R.B.Cs., and there seems to be a sort of a dead stop at that. Nothing seems to improve them or, if at all, the progress is very very slow. The enlargements of spleen reduce only to the level of fibrosis; beyond that nothing helps them; but when there is a response, the reduction in their size is something marvellous. Spleens that occupied the whole of the abdominal cavity and were felt low down in the pelvis, have been reduced to the extent of just being palpable. It is the extreme cases that are very difficult to handle. Unfortunately for these patients many of them cannot stay in a hospital long enough. Wherever there has been some improvement, patients have stayed for over 6 to 8 months and yet at that time one cannot pass them as fit and normal individuals to be sent out. Since most of them are farmers and farm-labourers, they get back too soon to attend to the farmyard work or it may be that somebody brings them information from the village that a calf has been killed by a wild animal; nothing can keep them back when such news arrives. They rush back to the villages only to get worse very soon and either collapse there or come back to the hospital in a much worse condition. The artificial surroundings of a hospital and the diet supplied there, they cannot get in their homes. Unless they are educated in a proper form so that they understand what health means to themselves, to their family, and to their country at large, this constant and rapid depopulation in this part of the country will go on. Recently one of us had a conversation with a large estate owner in the interior of this part of the country. The gentleman informed him that if the government did not take some radical step soon enough to prevent this depopulation, the gardens and fields would be no more there in a few years and the country would be one wide area of jungle. In his opinion there was no labour available at all. Even at the increased rate of payment of wages people refused to go to these parts and settle,

because of ill health. Fresh and vigorous blood must be brought into the country to settle down living under all sanitary principles. This alone seems to be the remedy. Otherwise it is a fight against all odds to try to cure these people. Nay, it is a waste.

We have tried in these cases the various products of liver extracts of different makes like Anahæmin, Neo-hepatex, Hepatex T., Reti-culin, T.C.F. Liver Extract, etc. It is observed that Anahæmin and Neo-hepatex give a good initial stimulus in cases in whom the colour index is above 1. This is later kept on well by other crude liver extracts. In some cases intra-muscular blood has also given the starting stimulus. Later, crude liver extracts maintain the regeneration better than the highly potent liver extracts. We might mention that cases where Campolon has been exhibited, quicker changes are noted. No two cases respond similarly to the same brand of liver extract. Very rarely have we found any anaphylactic reaction of a serious nature setting in. In only one extreme case where a potent liver extract had to be exhibited, and where it was reported that the person did not tolerate any sort of a parenteral treatment with liver extract, the patient had to be desensitized first.

Conclusion

1. A study of 2,000 cases of anæmia admitted to the McGann Hospital, Shimoga, and spread over a period of 4 years has been made.
2. Most of these cases are tropical, nutritional, macrocytic, hyperchromic anæmias.
3. The main causes are malnutrition or deficient nutrition, malaria and helminthiasis.
4. Contributory causes are a degenerate or dead civilization, lack of education and poor economy.
5. No curative procedure is of any avail since it involves a large portion of the population.
6. Widespread sanitary measures involving a lot of finance, universal useful education, and raising the standards of living are the only remedy. This appears to be impracticable at present under the existing conditions.

The authors take this opportunity to thank Dr. V. V. Monteiro, M.B., B.S., F.R.F.P.S. (Glas.), L.D.S. (Eng.), Senior Surgeon with the Government of Mysore, Bangalore, for kindly affording the opportunity and facilities to study and report this problem.

CORRIGENDA

THE EFFECT OF PROCESSING AND SOURING MILK BY THE INDIGENOUS METHOD

The Indian Medical Gazette Fifty Years Ago

THE PASTEUR-CHAMBERLAND SYSTEM OF FILTRATION AT THE DARJEELING WATERWORKS

(Reprinted from the *Indian Medical Gazette*,
August 1897, p. 301)

GREAT interest attaches to the introduction of the Pasteur-Chamberland system of filtration in the Darjeeling Waterworks owing to its being the first occasion on which a town has been supplied with drinking water subjected to a system of filtration which aims at the exclusion of all micro-organisms that may be in the water at the time of its collection at the reservoir. The Pasteur system has been used with the greatest success for many years past, notably in the hospitals, barracks and public institutions of France, but never on any very large scale. Naturally, sanitarians are awaiting with interest the result of the installation at Darjeeling; for, if it meets with the success there that is anticipated, there can be little doubt of the introduction of the system into other towns and localities.

For many years past the Darjeeling drinking water has had a bad name. Complaints have been repeatedly made both by the Public and the Press as to the condition of the water-supply, and medical opinion has always been unanimous that much of ill health at Darjeeling has been due to this cause. Analysis, both bacteriological and chemical, supports this view. In 1894, Surgeon-Lieutenant-Colonel Cobb, then Civil Surgeon of Darjeeling, when visiting the Indian Medical Congress, had an opportunity of becoming acquainted with the working of the Pasteur system, which was then on exhibition there. Having previously been much impressed with the necessity for an efficient method of filtration for the Darjeeling water, it occurred to him that the system was well adapted for this purpose. He accordingly wrote for the Darjeeling Municipality a note on the subject, entering fully into the reason for the adoption of the filter. This note was published in the *Indian Medical Gazette*. Much opposition was at first brought to bear against the project, but with the invaluable assistance of Mr. Greer, Deputy Commissioner of the district, who fully realized the importance of Dr. Cobb's proposal, and who did everything in his power as Chairman to advance the scheme, the Darjeeling Municipality towards the end of 1895 decided to adopt the Pasteur-Chamberland filter for their water-supply, and Messrs. Heatly and Gresham were entrusted with the work. These gentlemen have now completed their work, and we are informed that the filters are ready for use.

The filter consists of 38 cells of tough cast-iron lined with acid-resisting composition and arranged in four rows. Each cell is connected by wrought-iron pipes to cast-iron mains, which deliver into cast-iron collecting mains, all of which are protected with a similar composition. The cells are fitted with gunmetal valves, allowing any one cell or group of cells to be isolated for cleaning or other purposes; a travelling crane allows of any cover to be readily taken off if required. Each cell contains a number of Pasteur filter tubes in the well-known form, fixed into a solid elastic block which forms an impermeable joint. The inlet and outlet pipes are controlled by valves in the ordinary way, and, by means of small air compressor, the mechanical and bacterial soundness of each cell, or any group of cells, with their constituent filter tubes, can be immediately tested. This is owing to the circumstance, apparently peculiar to the remarkable medium of which the Pasteur tubes are composed, that, when soaked with water, the minutest invisible flaw will permit the passage of air under a pressure of 10 lb. to 15 lb. per square inch, while, if sound, it will retain it. The cleaning is effected by means of a circulating pump, fed from a small boiler fitted with Gresham's combination injector. This forces through the tubes of any cell or group of cells a solvent—usually a diluted acid—by which the dialytic deposits in the pores of the filter tubes is removed, while the whole of the filtering system is sterilized, and as the acid can be used again and again, it is accordingly both economical and free from objection. Arrangements are also made for sterilizing by steam. The whole of the parts of the installation is interchangeable. The installation will be worked by one man, who could, indeed, attend to a much larger system. The tubes wear for practically an indefinite period and the cost of upkeep is accordingly relatively small. It apparently only remains now for the system to be put into operation, and its effects on the water-supply and the health of the Darjeeling population to be carefully observed and recorded.

LONDON LETTER

(Reprinted from the *Indian Medical Gazette*,
August 1897, p. 303)

THE Jubilee proceedings are ended and happily without disaster. Never, in the whole history of Great Britain, were the national feelings so acutely affected as on this occasion, and from one end of the kingdom to another, these found vent in fêtes and rejoicings, processions, displays, feasts, bonfires and illuminations. London underwent a complete transformation. Its principal streets through which the Royal procession passed were placed beyond recognition by stands and boardings, bunting and baize, festoons and flowers and gay decorations of every sort. But there was hardly a domicile in

the whole of London, however poor or small, which did not hang out a flag or show a coloured light. The trains carried millions of people to and fro, and the thoroughfares were crammed with conveyances and pedestrians. Yet so admirable were the precautions adopted by the police and the Railway Companies that no accident of any importance occurred in any part of the kingdom. The day of the procession was a hot one, and the crowded streets stifling. Many cases of mild heat stroke occurred among both soldiers and spectators, but stretchers and ambulance wagons were at hand and every appliance ready for restoring the faint and reviving the weak.

The great Naval review at Spithead and Military review at Aldershot also passed off without a hitch, and the august personage in whose honour the celebration was held went through all the trying proceedings connected with it without faltering or fatigue. The newspapers have been full of resumes and reminiscences *usque ad nauseam*.

The Medical Press had not been wanting in this respect, and surgical progress during the last sixty years have been presented by the *Lancet*, *British Medical Journal*, the *Practitioner* and other journals. It is a marvellous tale and well worth the telling; anæsthetics, antiseptics, and the Roentgen photography are probably the most dramatic elements in the narrative; but the birth and development of sanitation and preventive medicine constitute the most remarkable, valuable and fruitful outcome of the period.

The era has been noteworthy on account of two great controversies which have profoundly affected medical science and practice. The first was the change of type controversy. The abandonment of blood letting and other spoliative and depletory measures in treating diseases was held by one school to be due to the advance of knowledge and the advent of more enlightened conception of what caused and constituted disease and of what was necessary to avert or cure. According to another school, represented by the older and more conservative men, the change in practice was considered to be owing to a degeneration in the constitution of human beings in consequence of which pathological processes presented a more asthenic complexion demanding support by food and wine rather than suppression by lancet, emetic and purge. The debate waxed warm, at times almost violent, but the result was that diseases were no longer treated, as malignant entities to be expelled by evacuants but as phases of disordered life to be rectified by time, rest, nursing and a careful and thoughtful encouragement and support of the *vis medicatrix naturæ*. Disease processes are now known to be in many, perhaps in most instances, to be conservative or recuperative in their action, and the rational treatment of disease in the present day tends to travel backward along the path of causation and endeavour to keep the spring of life free of contamination at its origin and to prevent pollution

of the stream as it proceeds by anxious attention to the environment. The other controversy in which the names of Pasteur and Pouchet were prominent concerned the question of spontaneous generation which has been finally and absolutely set at rest by the ingenious experiments which have demonstrated anew the truth of the old doctrine—*omni vivum ab ovo*; and have opened the portal of the great and promising study of bacteriology. The creation *de novo* of living forms may have occurred in geologically remote epochs, but no such process takes place in the present day, and even minor adaptive changes in the form and structure of living beings, caused by the force of evolution, are slight in character and slow in manifestation. So that fortunately for us and our art we can still place reliance on the great laws and uniformities of nature and eliminate from our thoughts and expectations all chance of probability of starting apparition of novel beings even of microscopic dimensions.

I am glad to observe that both in India and in this country the necessity of a law of medical registration is being again urged. The public ought to be protected against incompetent practitioners, and the State ought to insist on competence founded on proper training and testing and to declare by means of an official register the names of persons who have obtained medical degrees and diplomas on conditions which ensure sufficient knowledge and skill in their possessors. Certainly no private body or association should be permitted to grant licences to practise without State sanction conferred after taking guarantees and *bona fides* and soundness. My own firm opinion is that for the present the Indian Universities should be utilized as the instruments of testing and conferring medical qualifications; and that no medical college or school should be permitted to exist which is not affiliated to a university under conditions which should insist on proper arrangements and appliances being provided for teaching and training. It is contended that a diploma is wanted in India on easier terms as regards preliminary knowledge and special education and the final examination than the universities consider obligatory. I am convinced that the licences of the universities are granted on as easy terms as it is safe to concede, and that to lower medical education and the granting of diplomas to practise beneath the standard would be to degrade the profession and set loose incompetent practitioners.

It is argued that these find their way into practice in the shape of failed students notwithstanding, and that a cheaper diploma would bring many of these men into the fold of legitimacy. But, however low the standard is reduced, there will still remain the incompetent irregular practitioner who cannot be prohibited from practising as long as he manages to escape the clutches of the criminal law. It is vain to

attempt to bring these men within any scheme of medical registration which should include only those who have obtained qualifications declared by the law to be sufficient to entitle their holders to practise the medical profession, fill public medical and sanitary appointments, grant certi-

ificates of health, sickness and death, sue for fees in courts of law, give evidence as specialists, and generally perform such acts of a public or a quasi-public character as may fall in their way; all unregistered practitioners or persons being held legally disqualified to fulfil such functions.

Current Topics, Etc.

Exfoliative Dermatitis from Gold

(Abstracted from the *Journal of the American Medical Association*, Vol. 133, 8th March, 1947, p. 733)

BRITISH antilewisite (BAL) (Hynson, Westcott and Dunning) has been used in several cases of dermatitis due to gold with gratifying results. However, the number of cases is as yet too few to be conclusive and the response to BAL was most satisfactory when the rash had been present for less than two months. In one case in which the rash had been present for over three months, improvement following the use of BAL did not occur, since presumably after about three months the process tends to become irreversible. At present, with its apparent innocuousness BAL should be tried. BAL is prepared as a 10 per cent solution and for a person weighing 150 pounds (68 kg.) the dose has been 150 mg. (1.5 c.c.) five times a day for one day, four times a day for two days and three times a day for three days. This should be given deep intramuscularly. Toxic symptoms consist of nausea and vomiting, fibrillary twitchings and salivation. If these appear, the next dose should be omitted. When BAL is effective, the pruritus usually stops within twenty-four hours of the institution of treatment. If the pruritus is not affected by BAL, radiotherapy can be tried and is helpful at times. For local application, petrolatum ointment with 1 per cent phenol can be used and is apparently not harmful. It is unlikely that the pigmentation will completely disappear within five or ten years.

The Public Health Service as a Career

By SMr ALLEN DALEY

(Abstracted from *The Medical Officer*, Vol. LXXVI, 28th September, 1946, p. 137)

THE imminent social changes in England have been preceded by a quieter, but no less fundamental change in the public health curriculum and examinations. Official preventive medicine to-day includes many posts in such fields as tuberculosis, maternal and child health, epidemiology and venereal disease which are essentially clinical. The holders of these posts in many instances have no desire to hold appointments as medical officers of health and have hitherto spent time in acquiring the D.P.H. which would be better spent in acquiring experience of their own special branch of work. Some knowledge of public health is, however, essential in these branches, and to meet the need the General Medical Council has approved a course of whole-time study of not less than an academic term of ten weeks or equivalent part-time instruction. This covers such subjects as the history of public health and public assistance, the existing functions of central and local authorities and voluntary organizations, social security, international health organizations, vital statistics, epidemiology, environmental hygiene, the principles of health education, etc. This course is followed by a new examination and the issue to those who negotiate it of a Certificate in Public Health (C.P.H.). Universities and licensing bodies throughout the country have now held their first C.P.H. examination and in theory some hundreds of men and women are free to apply

for posts as assistant medical officer of health. Strikingly few are doing so; the vast majority are proceeding to the two further academic terms of work which leads to the D.P.H. This may be a temporary phenomenon. Service experience has probably given a good many men a chance to display latent administrative talent which would have had no opportunity to manifest itself in peace-time domestic medicine. These, naturally, will wish to secure the full qualification for an administrative public health post, and it is equally natural that many others, contemplating a career in some clinical branch of the public health field and with no administrative ambitions, should take one rather than two bites at the cherry and proceed to the full specialist qualification. It will be of great interest in the next few years to observe the relative numbers of those who limit themselves to the C.P.H. and of those who take the D.P.H. If a large majority follow the second course, one of the main objects in introducing the C.P.H. will have been nullified. Even if that happened, however, it by no means follows that the innovation will be a failure. The deductions from present limited experience appear to be that the three months' general course and examination give the student a background which will enhance the value of the subsequent six months' training.

This period of training also has changed considerably from that given for the pre-war D.P.H. Systematic instruction in physiology, and nutrition, bacteriology, parasitology, community diseases, sanitation, statistical methods, medical administration, public health law, the mental health services and occupational health, is supplemented by infectious disease hospital practice, and regular attendance at an approved public health department. An essential part of the D.P.H. examination is the presentation by each candidate of a day-book, in which he has made regular entries with observations and conclusions on the subjects of practical instruction in the course, and a dissertation on an approved subject.

This revised course, which gives due weight to the views and experience of the Society of Medical Officers of Health, among other bodies, shows the continuing keen interest of the General Medical Council in public health education. Most people of experience would agree that both the C.P.H. and the D.P.H. courses are functionally very well adapted to the purpose they are designed to serve, and no man, whatever his branch of medicine, would fail to derive benefit from one, or both when two years of post-graduate experience have qualified him to enter the course.

A Danger from Infested Drugs

(Abstracted from *The Pharmaceutical Journal*, Vol. 158, 25th January, 1947, p. 60)

FROM time to time we have drawn attention to insect infestation of crude drugs, and indeed the danger of deterioration from this cause is a constant cause of concern to those who hold stocks of these products. From the point of view of the pharmacognocist, the problem has not been concerned with measures to prevent infestation and to recognize the signs of deterioration when it has occurred. There is, however, another aspect of the danger which must be considered

THE USES OF VITAMIN E

While the main use of vitamin E up to the present has been the treatment of cases of habitual abortion and sterility of dietary origin (with success in about 70% of cases when whole oil—as in Fertitol—was given) wheat germ oil is being increasingly used for cases of primary muscular dystrophy, amyotrophic lateral sclerosis, anterior poliomyelitis and in rarer cases such as amyotonia congenita.

There are some indications that other factors in Bemax, probably part of the B complex, render the action of vitamin E more effective and it may, therefore, be desirable to reinforce the action of Fertitol in this way.

FERTITOL

Wheat Germ Oil Capsules

A highly active natural and stable source of vitamin E. Each 5 minim capsule is standardized to contain 3 mg. α-tocopherol.

Complevite

COMPLETE

in the most important vitamins and minerals

BALANCED

to meet known deficiencies in the average diet

CONVENIENT

dosage, in tablet form

ECONOMICAL

— a single supplement for manifold deficiencies

The graph below shows the multiple nature of Complevite tablets and also demonstrates the extent to which Complevite ensures optimal nutrition.

*The iron in Complevite exceeds the calculated deficiency expressly to combat the nutritional anaemia so common in children and in women of child-bearing age.

THROUGH AND THROUGH WOUND OF THE NOSE

Skin Grafts supported by stent moulds and dressed with Tulle Gras. Fixation secured by Elastoplast

CASE HISTORY :

On the 18th July, 1944, the patient sustained a through and through wound of the nose. Examination showed considerable loss of soft tissue on either side, but a continuous strip ½ in. wide remained along the bridge. The edges of the wound were excised on the 28th July. Two stent moulds were then made to support a

June 7th, '45. Creases and scars excised. Left airway established.

September 13th, '45. Width of base of nose reduced. Fleshy tips straightened.

June 27th, '46. Examination showed the flaps to have settled in very well

all over, and the airway completely established.

The details and illustrations above are of an actual case. T. J. Smith & Nephew Ltd., of Hull, England, manufacturers of Elastoplast and Jelonet, publish this instance—typical of many, in which their products have been used with success.

Fig. 1

skin graft, prevent the raw surfaces adhering, and provide a good airway. A forehead flap conveyed by a curved left temporal artery flap was raised, and dermatome grafts were placed over the stent moulds to join the nasal linings, before the flaps were sutured into position. A dressing of Jelonet was applied with Elastoplast fixation.

August 26th, '44. Forehead flap severed.

November 30th, '44. Bone graft to nose.

TRANQUILLITY

A calm outlook and freedom from worry and nervous tension are rare in these days. The intense application to war work and consequent mental and physical strain are revealed in widespread headaches and insomnia.

Veganin may well be used to soothe the overwrought nerves, relieve pain and induce sleep. It is a synergistic combination of acetylsalicylic acid, phenacetin and codeine, and is widely known as a dependable and highly effective analgesic, sedative and antipyretic. Veganin is neither toxic nor habit forming.

in the light of a report in the *British Medical Journal* (11th January, 1947, p. 54), on 'An Unusual Case of Intestinal Myiasis', from which it appears that the use of insect-infested drugs may present a danger to the patient. The report describes a single case of a woman who, for two weeks, suffered from frequent attacks of diarrhoea and constipation accompanied by some general abdominal pain of a colicky nature and the passage of blood per rectum. Larvæ were isolated from the stools and identified as *Plinus tectus* Boield. It is suggested that the eggs of the insect protected by their outer chitinous membrane, passed through the stomach and subsequently developed into larvæ in the more alkaline portion of the bowel. The larvæ might resist the effects of peristalsis for some time by clinging to the villi by means of the sharp claws on the legs and the biting jaws. Treatment of the patient with one fluid ounce of liquid paraffin nightly for a week gave a satisfactory result.

The coleopterous insect *Plinus tectus* is widely distributed throughout the world, and was first reported in Great Britain in 1901, but has since become widespread. It has been found in many dried food products, such as figs, beans, maize, cocoa beans, and in some drugs and spices, including almonds, nutmeg and ginger. The allied species *Plinus fur* has been more frequently reported in crude drugs, and a comparative description of the two insects, with drawings of *P. tectus*, are given in an article in *The Pharmaceutical Journal* for 5th June, 1937, p. 577. The eggs are less than 1 mm. in length, ovoid and white; the larvæ are about 4 mm. long, very hairy, dirty white in colour and, in the resting position, distinctly curved. There appears to be no evidence that in the recent case of intestinal myiasis the larvæ were derived from an infested drug, and, in view of the more common infestation of packed cereal products after domestic storage, the latter may be considered as a likely source. The danger from infested drugs should not be exaggerated, but it is clear that care must be exercised, particularly with powdered drugs, and rubbed herbs used for making domestic infusions, for, although the eggs of insects are destroyed on boiling, maceration in tepid water may permit survival. It is usually impracticable to store large quantities of crude drugs in sealed containers, but when relatively small stocks are held, they should be stored in well-closed containers and examined at intervals. Grossly infested material should be destroyed by burning, but when not more than a trace of infestation has occurred, it may be eliminated by adding a small quantity of chloroform, carbon tetrachloride, or carbon disulphide to the material in the container, taking care that closure is perfect.

The Complement Fixation Reaction in Asiatic Schistosomiasis Employing Cercarial Antigen

By F. ELEANOR WILLIAMS

(Abstracted from the *Transactions of the Royal Society of Tropical Medicine and Hygiene*, Vol. 40, March 1947, p. 421)

AN extensive serological survey by means of the complement fixation reaction was made in 560 members of the R.A.A.F. exposed to infection with Asiatic schistosomiasis over a period of 16 days at Leyte in the Philippines. The antigen used was an 18-year-old alcoholic extract of the livers of snails (*Planorbis exustus*) infected with cercariæ of *S. spindale*. It had been prepared in India by Fairley's technique and was despatched to Australia in 1927.

The sera from 169 individuals (135 of whom had already received treatment) yielded positive complement fixation reactions of different intensity; the amount of complement fixed varied from 3 to 40 M.H.Ds. Ova were demonstrated in 144 of these cases and were not found in twenty-five instances.

In 391 individuals whose sera yielded a negative complement fixation reaction, repeated examinations of the stools revealed ova in only five instances.

Of 365 individuals who were previously regarded as not infected and who received no treatment, thirty-four (9.3 per cent) yielded a positive complement fixation reaction and twenty-seven (7.4 per cent) showed ova in the stools. Twenty-six of the twenty-seven with demonstrable ova in the stools showed a positive serological reaction.

A comparison of the complement-fixing power of the sera and the ova content of the stool indicated that the persistence of a strongly positive complement fixation reaction (7 M.H.D. or over) 6 months after treatment is evidence of persisting infection, i.e. living schistosomes.

No evidence of false positive reactions was recorded in non-bilharzia sera, and positive reactions were never noted in Wassermann-positive sera collected from individuals not exposed to schistosome infection.

The serological reaction proved of outstanding value as a less tedious and a somewhat more laboratory test than repeated faecal examinations for ova. No investigation in an outbreak of this kind would be complete unless the complement fixation reaction on sera as well as stool examinations were carried out in individuals exposed to infection. Both laboratory procedures are essential if the true incidence of schistosomiasis is to be determined.

The presence of persisting positive serological reactions in the absence of demonstrable ova is explicable on the basis of (a) unisexual infection at the time of exposure, (b) the exclusive or predominant survival of male worms following treatment, and (c) the mildness of the original infection, there being so few worms that ova were not present in sufficient number to be demonstrable.

Benign Lymphocytic Meningitis

By B. W. MURPHY

(Abstracted from *The New Zealand Medical Journal*, Vol. XLVI, February 1947, p. 37)

Two cases of benign lymphocytic meningitis are presented. A substantial reduction in the level of cerebro-spinal fluid chlorides was found in both. The reduction in chloride level usually regarded as being suggestive of tuberculous meningitis was misleading.

The diagnosis of benign lymphocytic meningitis appears justifiable on both clinical and laboratory grounds. The disease is commonly associated with respiratory infections. The first patient had an 'influenza-like' illness before admission; the second showed evidence of upper respiratory infection. In neither was there anything to suggest that the patient had recently suffered from any of the acute specific fevers occasionally followed by a meningo-encephalitis. There was no evidence of involvement of brain, cord or nerve roots.

Both patients developed the clinical picture of a moderately severe meningitis of fairly acute onset and both made a rapid and complete recovery.

Benign lymphocytic choriomeningitis frequently follows a respiratory infection. Headache, malaise, vomiting and fever develop, usually acutely. Signs of meningeal irritation are present. Papilloedema may or may not be present. The cerebro-spinal fluid shows the following changes. The pressure may or may not be increased. Globulin is moderately increased. A predominantly lymphocytic pleocytosis is present, counts ranging from 30-1,500 cells. In the initial stages polymorphs may predominate.

In the examples here reported the chloride figures were well below the normal standard of 725-750 per 100 c.c.

A filtrable virus which produced a constant type of lymphocytic infiltration of the meninges and choroid plexus in experimental animals has been recovered from the spinal fluid of patients with this disease. The

specific virus is probably responsible for most of the cases, but other pathogenic agents may produce the syndrome.

In the second case the history together with the low chloride level in the spinal fluid suggested tuberculous meningitis in the first few days of illness. It would appear that a reduced chloride figure cannot be relied on entirely to distinguish between these two conditions.

Limitations of Folic Acid

(Abstracted from the *Lancet*, i, 1st February, 1947, p. 182).

THE value of folic acid in the treatment of pernicious anæmia can be regarded as established, but at the present price (1s. 2d. for 10 mg.), it is so much more expensive than parenteral liver treatment that it is likely to be reserved for difficult cases. In non-tropical sprue results have been irregular: some patients have responded well, others only partially or slowly; some have improved so far with folic acid and then further progress has been obtained with proteolysed or ordinary oral liver treatment, while others have shown the reverse. The preliminary results in coeliac disease, which are all we yet have to go on, suggest that the response is slow and that perseverance in treatment is necessary before failure is conceded. That some patients with non-tropical sprue or coeliac disease and a normoblastic marrow would not respond was to be expected because it is reasonably clear that folic acid is effective only where megaloblastic erythropoiesis is present.

In this issue Spies and Stone report an observation which, if confirmed, will establish a serious limitation in the value of folic acid in pernicious anæmia; for they find that folic acid has no effect on the degeneration of the posterolateral tracts of the spinal cord commonly associated with the disease. Not only has folic acid failed to relieve this syndrome but the neurological signs have worsened while the patient was receiving it; and similar results are reported with thymine. All the patients recovered when given an ordinary concentrated parenteral liver extract. It will be recalled that Doan noted a remission of minor neurological signs—presumably due to peripheral neuritis—in his cases of pernicious anæmia given folic acid, and none of his patients had developed neurological changes while on treatment; so far this has also been the experience in this country, but there has probably not been sufficient time for any such complications to appear.

The findings of Spies and Stone have practical and theoretical implications. The practical ones are that cases of pernicious anæmia on regular folic acid must be carefully watched for the onset of posterolateral cord signs and promptly put on liver extract if these appear; and when such signs are already present the patients are best treated with liver. On the theoretical side this report would have delighted Arthur Hurst, who contended that the hæmopoietic factor was distinct from the neurotrophic factor. It fits in too with other evidence suggesting that folic acid cannot in every case of pernicious anæmia completely meet the deficiency that is filled by a liver extract that some cases are also suffering from the lack of an unidentified factor.

Habitual Hyperthermia: Premenstrual 'Fever'

By H. A. REIMANN

(Abstracted from the *Journal of the American Medical Association*, Vol. 132, 21st September, 1946, p. 144).

IN 1932 under the title of Habitual Hyperthermia the writer reported the case of a woman aged 23 whose temperature had often been above the average normal for eighteen years. The 'fever' led a succession of physicians to seek for infection or other causes of it and led to a long period of unnecessary, enforced semi-invalidism. On prolonged study the temperature

was shown to have a regular relation to the menstrual period. It was normal or subnormal during the first half of the menstrual cycle, rose to levels higher than normal at the mid-period when the follicle matures and persisted at high levels until the day before the menses, when it dropped again.

In the majority of women the rhythmic fluctuation of the temperature seldom exceeds the average normal level of 37°C. (98.6°F.) and is usually unnoticed unless careful registrations are made. In certain otherwise normal women whose temperature rises above normal, prolonged and unnecessary search for the cause of 'fever' is often made unless the temporal relation of the fluctuation to the menstrual cycle is recognized. The problem of diagnosis is greater when a neurosis also is present.

At the time the report of the case was published it was planned to observe the effect of the course of time and especially of pregnancy on the cyclic temperature curve, but the patient married and lived in China until recently. During that time there were six pregnancies, resulting in 4 living normal children, an attack of typhus, several bouts of malaria and the usual hardships in a war-torn country. Unfortunately, the exigencies of living prevented measurement of the temperature during the periods of pregnancy. No further study was made until the patient returned to this country in September 1945, fourteen years after the previous report was made. Registration of the temperature twice daily over two menstrual cycles revealed the usual course of events with low temperature of 36.1°C. (97°F.) from the first day of the menstrual period to the mid-period, an abrupt rise to 37.4°C. (99.3°F.) then a fall to subnormal the day before the next period. No other signs or symptoms occur.

While the periodicity of the 'fever' in the childhood of the patient is not known, temperature at fever levels was first noted at the age of 5 and has continued, later in rhythm with the menstrual period, for thirty-two years. It will be of interest to see what effect the menopause will have on the temperature.

Treatment of Typhoid Fever with Type Specific Bacteriophage

By E. G. KNOUF *et al.*

(Abstracted from the *Journal of the American Medical Association*, Vol. 132, 21st September, 1946, p. 134)

Type specific bacteriophage was used intravenously in the treatment of 56 patients with typhoid fever. Three patients had complications before treatment began, but recovery occurred. The mortality for the series was 5 per cent.

Treatment by means of type specific bacteriophage offers a promising and safe procedure against typhoid fever. Patients must have careful general care according to their particular needs. Type specific bacteriophage is the accepted form of therapy against the disease in the Communicable Disease Unit of the Los Angeles County General Hospital for all patients whose *Eberthella typhosa* organisms can be typed.

Congenital Pyloric Stenosis

(Abstracted from the *British Medical Journal*, ii, 14th September, 1946, p. 407)

CONGENITAL pyloric stenosis is undoubtedly inherited, but it is uncertain whether the disorder is recessive or dominant. Studies of large numbers indicate a higher degree of cousin marriages among the parents than would be expected on a chance sample of the population, which favours a recessive gene. On the other hand recorded instances of a child and his parent both having the disorder are not uncommon, and pedigrees have been published which give the appearance of a dominant gene. The condition has been found at birth

and even in a foetus, so that the cause must be prenatal and not due to feeding or any postnatal factor. Some disorder of the autonomic system is usually postulated, but it is also said that the so-called hypertrophied muscle is abnormally packed with glycogen, as is found in Von Gierke's disease.

Sensitivity to Penicillin

By W. J. O'DONOVAN

and

I. KLORFAJN

(Abstracted from the *Lancet*, ii, 28th September, 1946, p. 444)

THE case is recorded of a patient who became sensitive to penicillin in the course of ordinary dermatological treatment with penicillin spray.

Anaphylactic shock followed an intramuscular injection of penicillin.

Oral administration of penicillin brought about complete desensitization, abolishing superficial skin hypersensitivity and the shock effects of parenteral penicillin.

Actinic sensitivity developed and faded *pari passu* with penicillin sensitivity.

Medicolegal

A NAME MISHEARD

(Abstracted from the *Lancet*, i, 26th April, 1947, p. 571)

CONFUSION between the words 'procaine' and 'cocaine' led to a fatal accident and raised questions of liability for negligence. Mr. Justice Hilbery dealt with the facts in deciding the case of *Collins v. Hertfordshire County Council and King* last month. The circumstances he said were so extraordinary that he could not believe they were ever likely to occur again. Hospital managements it may be added will be alert to see that they do not.

A patient entered the Wellhouse Hospital at Barnet for an operation on his jaw. Arranging to give an injection before operation the surgeon telephoned an instruction to have ready 100 ml. of 1 0/o. procaine and 1/200,000 adrenaline. The message was taken by a student (not then qualified) acting as student house surgeon; she misheard the instruction and asked the hospital pharmacist to prepare a solution containing 1 0/o. cocaine. The operating surgeon injected 80 ml. of this solution—some four times the lethal dose—and the patient died. The widow claimed damages both from the county council (as the owners of the hospital) and from the surgeon who gave the injection.

The defendant surgeon stated in evidence that he himself always called the drug 'procaine'. The term 'Novocain' adopted by German manufacturers as its trade name had been commonly employed; but at the beginning of the late war the medical profession had been asked not to use it. He had never known of cocaine being given by injection and he had no idea that he had injected it. He could not understand an experienced pharmacist dispensing so large a quantity of a dangerous drug; the amount of adrenaline was unusual and the pharmacist should have queried it. The regulations, said the surgeon, require that dangerous drugs be dispensed only on the written instructions of a qualified medical practitioner; the pharmacist had dispensed this solution to an unqualified person without referring the matter back to himself or insisting on the signature of a qualified practitioner.

The judge found that the surgeon who gave the instructions by telephone and who made the injection was negligent. The surgeon had expected the student house surgeon who took the message to use her knowledge and reason and to apply her mind to what he was saying; but still the surgeon himself was responsible for not making sure that he was getting what he had ordered. The student house surgeon,

continued the judge, was negligent; she knew that the solution was required for an injection and she knew that the solution as prepared was lethal; she had not used reasonable skill or care. Further, the pharmacist was negligent. He had accepted an oral demand for an exceptional dosage of cocaine and adrenaline for injection and had not required the order to be initialed by a qualified person; he had not checked the demand with the surgeon; and he had disregarded all the prescribed safeguards including the cautionary instruction in the British Pharmacopoeia that when an usually large dose of a drug appears to have been prescribed the pharmacist or dispenser should satisfy himself that the prescriber's intention has been correctly interpreted. Finally, the judge found the hospital responsible. It was liable for the negligence of its two employees (the student house surgeon and the pharmacist) and it had failed to establish a proper system and to insist upon obedience to the rules about dangerous drugs. 'If the hospital had had a proper system this solution could not have arrived at the operating theatre let alone the body of the unfortunate patient.' The judge awarded £2,500 damages and directed that payment be borne equally by the county council (as owners of the hospital) and the surgeon.

It will be remembered that the risk of confusion between procaine and the proprietary preparation 'Percaine' was dealt with by the manufacturers of the latter changing its name to 'Nupercaine' (*Lancet*, 1942, ii, 221, 340). As Mr. Justice Hilbery deemed the circumstances in the *Collins* case unlikely to recur there seems no need to rechristen all our dangerous drugs with names chosen like those of the London telephone exchanges for their distinctive enunciation so as to avoid all possible risk of misunderstanding. With ordinary and proper care these accidents will not happen even when hospital staffs are overworked and undermanned.

COVENANTS IN RESTRAINT OF COMPETITIVE PRACTICE

(Abstracted from the *Lancet*, i, 3rd May, 1947, p. 610)

PARTNERSHIP or other agreements containing covenants restrictive of competitive practice may need different drafting in the light of a recent decision of the Court of Appeal.

Dr. D. J. L. Routh and Dr. T. D. G. Wilson practising at an address in Okehampton engaged Dr. C. G. Jones to assist them under an agreement which contained the following covenant. Dr. Jones undertook that within a radius of 10 miles from that address and within a period of five years from the end of the engagement he would not practise or assist any other person to practise any form of medicine, surgery or midwifery nor would he accept any professional appointment within those limits. The plaintiffs claimed that the agreement came to an end in February 1946, that the restrictive clause then came into effect and that an injunction should be granted to restrain Dr. Jones from practising within the 10-mile radius in contravention of the covenant.

These covenants 'in restraint of trade' are legally enforceable only if they are reasonable and not too vague. The classic statement of the law was uttered by Lord Macnaghten in *Nordenfelt v. Maxim Nordenfelt Co.* in 1894.

'The public have an interest in everyone's carrying on his trade freely; so has the individual. All interference with individual liberty of action in trading and all restraints of trade of themselves if there is nothing more are contrary to public policy and therefore void. That is the general rule but there are exceptions. . . . It is a sufficient justification if the restriction is reasonable—reasonable that is in reference to the interests of the parties concerned and reasonable in reference to the interests of the public so framed and so guarded as to afford adequate protection to the party in whose favour it is imposed while at the same time it is in no way injurious to the public.'

When the Okehampton case came before the Chancery Division last December, Dr. Jones pleaded that the agreement was too wide and that in the circumstances it was unreasonable. He tendered evidence of the shortage of medical practitioners in the Okehampton area and he said he was willing to give an undertaking for a period of eighteen months from March 1946 not to accept as patients any patients whose names were on the plaintiffs' books at the termination of the engagement. Mr. Justice (now Lord Justice) Evershed dismissed the claim with costs. The onus was on the plaintiffs he said to establish that the covenant was reasonably required for their protection. He considered one part of the covenant to be too wide and therefore unenforceable. The plaintiffs appealed but without success. The Court of Appeal has held that the restrictive covenant went much further than was reasonably necessary to protect the appellants' practice as general medical practitioners. The covenant would prevent Dr. Jones from setting up as a consultant or from taking an appointment as medical officer of health. In neither capacity would he be damaging the appellants' practice. The result was that the whole covenant was bad and the appeal must be dismissed with costs. Leave to take the case further to the House of Lords was refused.

Some of the older cases on restriction of competitive practice (like *Davis v. Mason* for instance where a fourteen-year restriction within a 10-mile radius was held good) are probably of little importance in modern conditions. Generally the law draws a distinction between a trade like a mail-order business where most of the work is done by post or possibly by telephone and an occupation like medical practice which requires personal attendance. In the former case wide areas of restriction are allowed by law; in the latter they are deemed less reasonable. The most helpful decision in recent years was that of *Eastes v. Russ* in 1914.

Dr. Eastes had initiated in Queen Anne Street in 1901 the business of a pathological laboratory; he examined and reported upon chemical, bacteriological and other specimens. His clients at first were mostly Harley Street consultants; but as his business grew his services were required by general practitioners who learnt to appreciate the value of this scientific development and by medical officers of health. In 1905, when he was employing several assistants, he engaged Dr. Russ as an assistant on terms that he would not engage in similar work within 10 miles of the laboratory. The agreement having been ended in 1912. Dr. Russ soon afterwards set up in Beaumont Street within half a mile of the Queen Anne Street laboratory. There was an element of life-long exclusion under the covenant. The Court of Appeal held that the agreement was wider than necessary. Lord Cozens, Hardy and Lord Justice Phillimore (Lord Justice Swinfen Eady dissenting and considering the geographical restriction to be no greater than was reasonable for protection of Dr. Eastes) took the same kind of view as the Court of Appeal has now taken in the Okehampton case.

It is clear that the advisers of medical practitioners must keep these restrictive covenants in future as narrow as they conveniently can.

Reviews

LIPPINCOTT'S QUICK REFERENCE BOOK FOR MEDICINE AND SURGERY.—By G. E. Rehberger, A.B., M.D. Thirteenth Edition. 1946. J. B. Lippincott Company, Philadelphia and London. Pp. ix plus 1461. Illustrated. Price, 90s.

The first ten parts of this book deals with general medicine and surgery, gynaecology, genito-urinary diseases, obstetrics, diseases of skin, eye, ear, nose, and throat, and orthopaedics, and the last one with the

drugs mentioned in the body of the work—their dosage, uses and mode of administration. Treatment of diseases is the main feature of the book, but in preparing the present edition, the author seems to have overlooked some notable advances. For instance, there is no mention of penicillin in the treatment of syphilis, gonorrhoea, septicæmia or pneumonia; indeed all that we could find about this drug is in a short note in the section on drugs. In bacillary dysentery, prominence is given to saline treatment followed by bismuth and opium, while sulphaguanidine is just referred to as a remedy of 'proven value'. Thiouracil has a place in exophthalmic goitre but is not mentioned. Another matter on which we wish to comment is the long lists of causes of diseases; it must be a tedious process to go through them and we wonder whether they have any value at all. But apart from these shortcomings the book fulfils the needs of the general practitioners for whom it is primarily intended. Treatment of diseases has been given generally in greater detail than in similar textbooks, and the laboratory tests are described where required. In addition to diseases the book includes subjects such as infant feeding, metabolism, food, roentgenology and blood transfusion. Finally, there are chapters giving tests of drugs and equipments required for surgery or hospitals in the various specialities which the beginners will find very useful.

PRACTICE OF MEDICINE (WRITTEN IN BENGALI):

—By Dr. Jotindra Nath Ghosal, L.M.S. Parts I and II. Published by B. Ghosal, 83, Karbala Tank Lane, Calcutta. Pp. 336. Price, Rs. 9 (in paper binding). Price, Rs. 10 (in cloth binding)

This book written in Bengali deals with the subject based on compilations from the literature and author's long experience in practice of medicine. It contains useful informations with interesting case notes, but it is not easy to read owing to incorporation of too many English terms spelt in Bengali such as constipation, paralysis, etc. Besides, there are many printing mistakes.

R. N. C.

AVIATION MEDICINE.—By Louis Hopewell Bauer.

Edited by H. A. Christian. 1943. (Reprinted from Oxford Loose Leaf Medicines.) Oxford University Press, London. Pp. 545 to 595. Illustrated. Price, 8s. 6d.

This little book which is reprinted from a section in Oxford Loose Leaf Medicines (with original page numbers 545-595) gives a concise account of physiology, internal medicine, ophthalmology, otology, neuropsychiatry and psychology which fall within the domain of the specialist in aviation medicine, now called the Flight Surgeon. All kinds of flights are considered.

The information given is for the benefit of both the pilot and the passenger. The medical officer of the air lines and the medical advisers of the air-minded sportsmen and travellers cannot do without it.

The description of the special apparatus used in testing candidates for training as pilots could be fuller. The 'ships' are really planes.

The paper, printing and binding are excellent and price reasonable.

S. D. S. G.

A HANDBOOK OF DISEASES OF CHILDREN.—By

B. Williamson, M.D., F.R.C.P. Fifth Edition. 1947. E. and S. Livingstone Ltd., Edinburgh. Pp. xii plus 408. 86 Illustrations, some in colour. Price, 15s.

This book is one of the handiest on the subject of children's diseases. The subject is treated system by system in a most readable form and there are 86 illustrations in the text. The treatment includes the use of biotics. Under Cooley's anaemia there is the mention of one authentic case in England. Von Jaksch's anaemia is no longer considered a clinical entity. The account of the Rh factor (p. 155) contains one

Effective and Low Dosage Sulphonamide Therapy
with

IRGAFEN

(N-3, 4-Dimethylbenzoyl Sulphanilamide)

A well tolerated chemotherapeutic agent with definite action.
Total dosage 30-50% lower than that of other sulphonamides.

Indications :

Pneumonia, meningitis, B. coli infections, strepto- and staphylococcal infections, dysenteric enterocolitis, etc.

Tablets — Ampoules

Asthenia

The incidence of asthenia and malnutrition demands a preparation of proved tonic powers which is admirably provided in Waterbury's Compound. The intake of this preparation, which contains as its components products obtained by the enzymatic action of pancreatic ferments on cod liver oil, livers and spleens, malt extract and hypophosphites, results in the stimulation of physical vigour and disappearance of the signs of inanition. Waterbury's Compound is agreeable to the palate and is suitable for administration to patients of all ages.

Mercantile Buildings, Lall Bazar, Calcutta.

Also at Bombay, Madras and Karachi.

Made by Waterbury Chemical Co., Inc., New York and St. Louis, U.S.A.

WATERBURY'S COMPOUND

Highly Active Glycoside of Digitalis Leaf

Digitaline Granules, A.&H., are granules of Digitoxin, B.P.C.—*Digitaline Cristallisée* of the French Pharmacopoeia. This is one of the most active glycosides of digitalis leaf; its action on the heart lasts much longer than that of digitalis itself, and it is often effective in cases where galenical preparations of digitalis have failed. The *Digitaline Cristallisée* used in Digitaline Granules, A.&H., is shown by biological assay to be of full activity.

It is important to distinguish Digitaline Granules, A.&H., from *Digitalinum purum Germanicum* the dosage of which is much greater than that of Digitaline Granules, A.&H.

In two strengths: gr. 1/240 (½ mg.), gr. 1/600 (1/10 mg.). In tubes containing 40 granules.

DIGITALINE

GRANULES A.&H.

ALLEN & HANBURYS LTD • CLIVE BUILDINGS • CALCUTTA
(INCORPORATED IN ENGLAND)

VITAPHOR

indicated in all cases of VITAMIN DEFICIENCY

VITAPHOR—the perfect TONIC is standardised to contain the following active Vitamins in each fluid ounce.

B₁ 450 International Units
C 1300 International Units
D₂ 1650 International Units
Plus
Glycerophosphate of Sodium,
Potassium Strychnine and
Magnesium

All combined with a suitable base which gives to this Tonic a pleasant and agreeable taste.

Prescribe Vitaphor in all cases of Convalescence from acute illness, in cases of undevelopment, faulty Nutrition and all "run down" conditions when the body is in a low state of health.

error: The Rh negative percentage applies to the European stock only, not to the whole world.

The paper, printing and binding are excellent, and the price is reasonable.

S. D. K. G.

TEXTBOOK OF BIOCHEMISTRY.—By Benjamin Harrow, Ph.D. Fourth Edition. 1946. W. B. Saunders Company, Philadelphia and London. Pp. xiii plus 592. Illustrated. Price, 22s.

The fourth edition of Prof. Benjamin Harrow's book perhaps gives more than is really needed by a medical student but is welcome. Chapters on vitamins, immunochemistry, chemotherapy, inorganic metabolism and hormones are particularly arresting.

The paper, printing and binding are very good and the price is not excessive.

Teachers and laboratory workers must have a copy.

S. D. S. G.

VITAMINS IN HEALTH AND DISEASE.—By J. R. Goyal, M.B., B.S. 1947. Published by Dr. J. R. Goyal, Burn Bastion Road, Delhi. Pp. 166. Price, Rs. 5. (Obtainable from the Medical Review of Reviews, Post Box No. 160, Delhi)

This small book contains a concise account of vitamins and their uses including lists of articles of diet with their vitamin content especially intended for those practitioners who have no access to the literature. We may offer one comment. Although absence of thiamin deficiency in individuals with very poor intake is attributed to bio-synthesis in the large intestine as observed by Najjar and Holt, it is stated elsewhere that human body is unable to manufacture vitamins except certain amount of vitamin D.

R. N. C.

MATERIA MEDICA FOR NURSES.—By Lois Oakes, S.R.N., D.N., and Arnold Bennett, M.P.S. Second Edition. 1947. E. and S. Livingstone, Edinburgh. Pp. viii plus 354. Price, 7s. 6d.; postage, 6d. (Home)

This textbook on Materia Medica should prove most useful to all student nurses preparing for the State examinations as it is written in such an interesting and concise manner. In the second edition new chapters have been added dealing with sulphonamides and penicillin which greatly increase the value of the book. A nurse who knows something about drugs and their uses and effects finds her work much more interesting and is bound to prove a better and more useful nurse to her patients and the doctors. The editors have tried to meet the needs of nurses and have not made the book too difficult. It is strongly recommended for the use of sister tutors, trained nurses and student nurses.

W. J. M.

IMPROVISED EQUIPMENT IN THE HOME CARE OF THE SICK.—By Lyla M. Olson, R.N. Fourth Edition. 1947. W. B. Saunders Company, Philadelphia and London. Pp. 265. Illustrated. Price, 7s. 6d.

This book with its great number of illustrations is certainly unique and should find a place in every home and in every District Nurses' and Midwives' Library. The many up-to-date ideas on improvising articles to use for the comfort of the sick either in the home or in the hospital when the real article required is not available, are practicable and easy and should help to stimulate ideas of further ingenuity of all who use this book. The chapter on First Aid should be of interest to all nurses and mothers and those in charge of children among whom accidents so easily occur. The present book being the fourth edition proves that it has been very popular and useful.

Abstracts from Reports

ANNUAL REPORT OF THE PUBLIC HEALTH COMMISSIONER WITH THE GOVERNMENT OF INDIA FOR 1945

FROM the year 1941 onwards, it became necessary to suspend publication of the full annual report of the Public Health Commissioner for various reasons, chief amongst them being the acute shortage of paper and printing facilities, diversion of some of the civilian staff to war work, recall to military duty of officers in civilian departments both from the Centre and the Provinces, difficulty in obtaining in time full reports of the provincial health activities, and lastly for reasons of security. Since the termination of the war last year, these difficulties are being gradually overcome. Brief reports for the years 1941, 1942, 1943 and 1944 have already been published. A preliminary note on the health conditions in British India during 1945 was published earlier this year as a new departure to provide a brief and early review.

Through the helpful co-operation of the Directors of Public Health of the Provinces it has been possible to obtain fuller reports of the work done during 1945. This report for 1945 is modelled more or less on the lines of the reports of the immediate pre-war years. It has not been possible, however, to publish it within six months of the end of the year to which it relates, which has been our objective in the past.

The year under review saw the termination of the global war first in the European and then in the Pacific Theatre. It left the world with widely devastated areas crying for rehabilitation, and a shortage of food and fuel supplies combined with difficulties of transport and communication. Under such circumstances the return to peace-time conditions could not be but slow. Malnutrition of populations on a scale not previously encountered could be expected. The threat of widespread world epidemics was apprehended. The pandemic of influenza in 1918-19 after World War I came readily to mind. In the United Kingdom the dreaded influenza did cause some alarm during the winter of 1945 but fortunately the worst fears did not materialize. In India, special watch was maintained at ports to check immediately any importation of influenza into the country. Spotting stations were organized in the provinces and a production of influenza virus vaccine was started on a preliminary scale at the King Institute, Madras.

In India, epidemics of cholera, smallpox and plague raged in a severer form than had been seen for many years past. Lack of sufficient medical personnel with the civil administration of the provinces and in some instances difficulties of supply of drugs and disinfectants hampered quicker control. In Bengal, some military medical units and personnel loaned from the army continued to render invaluable help to the civilian health authorities.

The control of epidemic diseases at fairs and large religious gatherings has improved by the insistence of some provincial authorities on pilgrims being previously

protected by inoculation. This measure has materially reduced the danger of spread of epidemic by the returning pilgrims.

War conditions had produced unprecedented expansion of aerial traffic to India especially through North Africa, and the danger of the introduction of yellow fever into India grew, since the arrangements that had been made at the outset of the war for the disinsection of infected planes before coming to India were becoming inadequate. The Government of India deputed two officers to study conditions and disinsection methods in North Africa. They reported that the disinsection arrangements for aircraft did not comply with all the conditions laid down by the Government of India. This resulted in the Government of India withdrawing recognition granted to disinsection certificates issued by any outside authority. The only disinsection certificates so far recognized had been those issued by the Egyptian and Sudan Civilian Authorities. These were, in consequence, no longer recognized with the result that any planes that had been to yellow fever infected areas were considered infected and all persons travelling in them and not holding valid yellow fever inoculation certificates had perforce to be quarantined at Karachi.

A review of the health conditions in British India during the year 1945 based on the monthly vital statistical returns received from the provinces has been made in the Preliminary Note which has been referred to in a previous paragraph. It is unnecessary to cover the same ground again. Recently, annual revised data for the whole year have been received from the provinces, though the data from some of them are still liable to slight alteration on final revision. These data generally support the remarks made on the health situation in the Preliminary Note.

The annual data referred to above show a total of 8,374,463 births in British India during 1945. This gives a birth rate of 27.3 per mille and indicates that the tendency towards a falling birth rate noticed in recent years may be lessening. During the quinquennium 1937-41 the maximum recorded birth rate was 34.5 per mille and the minimum was 32.0 per mille. In the years 1942 to 1944 it fell successively from 29.3 in 1942 to 25.9 in 1943 and 25.4 in 1944. In the year 1945 the birth rate increased by 1.9 per mille over the rate in 1944 but the birth rate in 1945 did not reach the normal level of the pre-war years. This increase in birth rate was shown by most of the provinces which had recorded a marked fall in birth rate in the previous years. The United Provinces, Bihar, Orissa, Bengal, Ajmer-Merwara, the Central Provinces and Delhi all showed a clear increase in birth rate. The rates in all these provinces with the exception of the last two were still much below the pre-war level. The highest increase was shown by Bengal from the low birth rate of 15.6 per mille in 1944 to 20.8 per mille in 1945. A decrease compared to the 1944 rate was nowhere considerable except in the case of Sind where the birth rate fell from 14.5 per mille in 1944 to 13.6 in 1945, but the Sind figures must be regarded with caution as being partly due to inefficient registration. The North-West Frontier Province and the Punjab showed a further slight decrease this year. The position in the remaining provinces, *viz.* Bombay, Madras, Coorg and Assam, did not show much variation over that in 1944. During the year 1945, the Punjab, Delhi and the Central Provinces continued their record of a birth rate well over 35 per mille. As has been remarked in the Preliminary Note the decrease in birth rate in British India in the recent years is a subject of considerable interest particularly in view of the last intercensus rate of increase in British India which gave rise to apprehensions of a fast increasing population.

On the other hand, the death rate for British India decreased from 24.1 per mille in 1944 to 21.5 in 1945. The total recorded deaths in 1945 were 6,608,766. In the quinquennium 1937-41 the maximum death rate was 24.3 per mille and the minimum was 21.1. The rates from 1942 to 1944 were 21.3, 23.6 and 24.1

respectively. The death rate in 1945 decreased by 2.6 per mille compared with the rate in 1944. A substantial fall in death rate from the 1944 rate was shown by the North-West Frontier Province, Punjab, Delhi, Bihar, Orissa, Bengal, Sind, Madras, Coorg and Assam. Here again the largest decrease was shown by Bengal which fell from a rate of 28.1 per mille in 1944 to 19.8 in 1945. Only the Central Provinces showed an abnormal rise from 30.0 per mille in 1944 to 39.1 in 1945. The death rates in Bombay and Ajmer-Merwara showed some increase. The position in the United Provinces was very much the same as in 1944. With the exception of the Central Provinces and Orissa, the death rates in 1945 were on the same level as in the pre-war years; in fact in some provinces the rates were markedly below that level.

The infantile mortality rate showed a marked decrease. Infant deaths in British India totalled 1,264,003 in the year giving an infantile mortality rate of 150.9 per 1,000 live births as against the rate of 169.3 in 1944. The rate in 1944 was the highest recorded in the last decade while the rate in 1945 was the lowest recorded in the same decade, and, in fact, is the lowest on record for British India. With the exception of the Central Provinces and Coorg, which recorded an increase, every other province showed a decrease in the infant mortality rate. In the cases of the United Provinces, Bihar and Bombay, the decrease was not so marked as in others. The rate in the Central Provinces was 256.6 per 1,000 live births and was the highest recorded in the last decade. In Coorg, the rate had come down markedly low, that is for Indian conditions, in 1943 and 1944 to the figure of 122 and 121 respectively. In 1945 the rate increased to 130.9 but this figure is still much below the rates obtaining prior to 1943.

The public health activities of the provinces continued to be markedly curtailed due to war-time difficulties of obtaining personnel and material. Consequently, no large-scale improvements in the public health conditions of the towns or villages could be undertaken. The teeming millions of the rural population in India still remain more or less unprovided with medical and public health amenities.

The vast needs of the immediate post-war years were looming large and both Provincial and Central Governments produced comprehensive and detailed plans for the development of widespread public health facilities as well as medical relief.

The completion of the work of the Health Survey and Development Committee under the chairmanship of Sir Joseph Bhore during the year is an event of unique importance. Such a wide survey for a country of this size is an achievement of note. For the first time an authoritative survey of the health conditions in India has been made available. Its recommendations are far-reaching. It lays stress on focusing attention on the early advancement of the vast and hitherto neglected rural areas. It envisages a State Health Service which combines the curative and the preventive aspects into one organization.

REPORT OF THE KASHMIR MEDICAL MISSION OF THE CHURCH MISSIONARY SOCIETY FOR THE YEAR 1946

THE year 1946 has been a difficult one on account of a very depleted staff and high prices in Kashmir. During the year over 2,000 medical and surgical cases were treated as in-door patients and more than 550 major operations and 2,000 minor ones were performed. The out-patient attendance was less than in the previous year which is attributed to various reasons, one of them being political disturbances in the State. There was an outbreak of cholera late in the year, but with the approach of cold weather, it did not assume severe proportions. The annual expenditure was over Rs. 63,000, while donations, subscriptions and offertories received amounted to a little over Rs. 13,000.

All who are interested in the work are requested to send their donations or subscriptions to the Mission.

R. N. C.

ANNUAL REPORT OF THE CHEMICAL EXAMINER'S DEPARTMENT, GOVERNMENT OF MADRAS, FOR THE YEAR 1946

THE total work of the department during the year amounted to investigation of 1,781 cases with 8,812 articles as compared with 1,639 cases with 8,347 articles in the previous year. There were 527 cases of alleged human poisoning, poison being detected in 210 (39.8 per cent). The commonest poisons detected were alcohol in 35, oleander in 25, datura in 22, opium in 22 and cyanide in 18 cases. The number of stain cases examined increased from 953 in 1945 to 1,021, while miscellaneous medico-legal cases involving the examination of firearms, explosives and other articles decreased from 112 to 107. The report contains a number of illustrative case notes.

R. N. C.

REPORT OF A MEETING OF THE ROSS INSTITUTE INDUSTRIAL ADVISORY COMMITTEE, LONDON, HELD ON 14TH FEBRUARY, 1947

At the seventeenth meeting of the committee held in London on the 14th February, the chairman, Mr. A. Wigglesworth, referred to the reorganization of the India branch, formation of a new branch in East Africa, housing in the tropics and investigation of the new insecticide gammexane that is now being carried out. Professor G. Macdonald, Director of the Institute, gave an account of the experiences of a recent tour in India in which he said that there was a general deterioration of health of the tea plantation labour which reached its lowest level in 1943. It was due to a variety of causes, e.g. poor nutrition, rationing, food distribution and changing economic conditions. The major disease problems in the estates are, he said, malaria, kala-azar, anaemia, respiratory and alimentary infections. In addition there are of course the problems of water supply, sanitation and housing. In the control of malaria there have been many successes and also some failures. The chief causes of failure were: (1) imperfect organization of anti-malaria work, (2) existence of unrecognized causes of malaria, (3) undue reliance on one single method of malaria control, (4) shortage of trained staff, and (5) administrative difficulties. The new insecticides and drugs should be of very real advantage and can be brought into immediate use; but Prof. Macdonald was concerned to find that DDT had not become generally available for industrial use and that formulations of DDT were starting to appear in quantity at the time of his visit; the latter make less effective larvicides. Not much is at present known of gammexane, but the results so far obtained are most promising. The value of mepacrine has proven on estates before the war, but paludrine has advantages over mepacrine and should control malaria in the dosage of two tablets per week at intervals of 3 to 4 days. In the control of kala-azar, too, the new insecticides may provide a solution to the problem, having a very potent effect on the sandfly.

Anaemia has become commoner than it was and is a problem of first importance. It is very much more common in places where there is a considerable mixture of new and old resident coolies, and he thinks that the mixing of different strains of infection might have some influence on its production. There is an undoubted nutritional factor; the effect of food rationing and control has been to accelerate the departure from home-pounded rice which contains four times as much iron as does highly milled rice. In addition the prices of some of the accessory foods have gone beyond the labourers' ability to pay for them. Prof. Macdonald does not believe that hookworm infection plays as important a part in the production of anaemia as it is

stated by some. There has been a marked tendency for increase in the more serious forms of respiratory infections such as pneumonia, most probably because the cloth is rationed allowing many labourers no change when they are out, and umbrellas are now almost unobtainable so that they get wet more frequently and thoroughly. Of the alimentary infections, amebic and bacillary dysentery is very common, but a great deal has been done by installation of pure water supplies; still other channels of entry such as direct contamination or contamination by flies remain. The bore-hole latrine has not proved successful in Assam owing to high water table.

Dr. R. F. Tredre spoke on health problems in Gold Coast mines where the African labourers usually arrive in a state of sub-nutrition, coming as most of them do from territories in which there is a definite shortage of food. They have a difficult time during the first year and are liable to contract respiratory diseases which are unquestionably the principal cause of sickness on the mines. Hookworm and bilharzia infestations are very common but malaria is not of much consequence, as a considerable degree of immunity develops after adolescence. Better amenities are now being provided in the way of canteen feeding, etc. Mr. P. J. Burgers spoke of malnutrition among the labouring groups in Malaya from the absence of their customary amount of rice, the present rate of which is only about $\frac{1}{2}$ lb. per day against $1\frac{1}{2}$ - $1\frac{1}{2}$ lb. which they were getting before the war. This is said to be one of the primary causes of industrial unrest. It seems that Malaya is not getting the expected supplies of rice from Siam. Finally Professor G. P. Crowden said a few words on thermal protection by whitewash. To begin with, whitewash absorbs only a small proportion of the energy in direct sunlight, hence when it is applied to exposed exterior surface of roofs and walls it lessens the penetration of solar heat during the day with the result that less thermal discomfort is caused by re-radiated solar heat by day and at night. Experiments have shown a lowering in this way of inside surface temperature of bedroom walls by 3 or 4 degrees F., or more at night.

PLAGUE CONTROL

SIR,—Elimination of the rat is one of the fundamental planks in plague control. Trying to tackle the problem in U.P. in 1946 and modifying the method in Mymensingh in 1947 I found the following procedure to be highly successful and economic too.

Some sticky substance like oil or molasses as it is, or diluted with water is to be placed in the opening of the rat hole or along the haunts of the rat, like corners of the room behind furniture and bales of food grains and holds of godowns and ships.

On the sticky substance is to be sprinkled lightly, sodium antimony tartrate powder or copper sulphate powder, that is an irritant. In village experiment, I used dried and powdered dhatura-belladonna leaves too, with copper sulphate. The result every time was the disappearance of the existing rat population from the place for a considerable period.

Yours, etc.,

N. Z. KHAN, M.B.,
MAJOR, I.M.S. (ex).

CALCUTTA.

ANTIBIOTICS

SIR,—Being engaged in a research scheme on 'Certain aspects of penicillin and other antibiotics' for the past two years in this department under the auspices of

the C.S.I.R., India, I had naturally read with great interest the editorial on 'antibiotics' published in the December 1946 issue of the *I.M.G.*, pages 537-38, and thus had occasion to note the mention you had just made about *Allicin*. Again it was interesting to read the letter by S. N. Gupta, appearing in the April 1947 issue of the journal, page 241, and the abstracts of the papers he had sent you. In this connection I would like to draw your attention to the fact that, we in this department were engaged in a detailed study of plant antibiotics and among them *allicin*. Besides evolving a neat and elegant method of obtaining *allicin* in a very pure state, and studying several of its biochemical and physiological properties, we were also able to demonstrate its remarkable antibacterial effect on acid-fast organisms like *M. tuberculosis*. Results of our earlier work have appeared in a note in *Nature* (157, 1946), and in a paper in *J.S.I.R.* (46, 1946), both of which are summarized.* The work on various other aspects regarding *allicin* as a general chemotherapeutic agent such as toxicity studies in animals, blood level tests, and ability to cure experimental tuberculosis infection in animals, etc., etc., is nearing completion and it is hoped will be ready for publication in the near future.

Yours, etc.,

R. RAGHUNANDANA RAO.

DEPARTMENT OF BIO-CHEMISTRY,
INDIAN INSTITUTE OF
SCIENCE, BANGALORE.

* R. Raghunandana Rao, S. Srinivasa Rao, S. Natarajan and P. R. Venkataraman. Inhibition of *Mycobacterium tuberculosis* by garlic extract. *Nature*, 157, 441, 1946. The following is an extract:

We prepared an antibiotic extract from *Allium sativum* Linn. by a slight modification of the method of Cavallito and co-workers, who found it to be effective against Gram-positive and Gram-negative organisms. In our experiments, *Mycobacterium tuberculosis* (human strain B 52, H., Kasauli) was employed as test organism for *in vitro* and *in vivo* studies. In the first group of experiments, flasks containing Long's medium (with ammonium malate instead of asparagine) with the extract in the form of emulsion so as to give concentrations of 2 mg., 6 mg., 12 mg., and 18 mg. per 100 c.c. of the media were inoculated with two loopfuls of *Mycobacterium tuberculosis* from a slant culture and incubated. No growth was observed after three weeks in any of the flasks containing the extract, while in the control the bacillus grew profusely. In the containing 2 mg. garlic extract per c.c. slight curdy submerged growth was observed from the fourth week onwards; but it was very slight and slow. This was confirmed by repeated experiments.

We then inoculated 17 c.c. of Long's malate media containing 6.5 mg. of extract per c.c. in the form of emulsion with three loopfuls of the bacillus from a slant culture and incubated it for 24 hours with a control similarly prepared but without the extract. Sub-cultures were made from the two samples on Dorset's egg media, and 2 c.c. portions were injected subcutaneously in the groin region into guinea-pigs. After four weeks, no growth was observed in the sub-cultures from the tube containing garlic extract, while there was good growth in sub-cultures from the control tube. The animals are under observation at present.

In the light of the above observations, garlic extract *in vitro* is bacteriostatic in low concentration and probably bactericidal in high concentrations. Experiments are now in progress to test the efficacy of the extract in guinea-pigs immediately after infection.

R. Raghunandana Rao, S. Srinivasa Rao and P. R. Venkataraman. Investigations on plant antibiotics. Part I—Studies on *allicin*, the antibacterial principle of *Allium sativum* (garlic). *Jour. Sci. and Indust. Res.*, 5B, No. 2, 31-35, 1946. The authors' summary is given below:

The antibacterial principle of garlic has been prepared from the cloves by a comparatively simple process.

The antibacterial action against typical Gram-positive, Gram-negative and acid-fast bacilli has been demonstrated. It exhibits also antifungal properties.

The stability of *allicin* in the presence of artificial gastric and pancreatic juices and blood has been studied. While the antibiotic is comparatively stable in the presence of blood and gastric juice, it is inactivated by artificial pancreatic juice.

The inhibiting action of *allicin* on the milk clotting activity of papain and the amylolytic activity of B-amylase seems to indicate that it probably acts by reacting with —SH enzymes of tissues.

BACK NUMBERS OF THE I.M.G.

SIR,—There must be at least some of your readers who do not destroy their copies of the *I.M.G.* after they have read them. Since almost all the important work in India has been published in the *I.M.G.*, we frequently find ourselves frustrated as we have no volumes prior to 1935. Could any subscribers please help us with numbers of the *Indian Medical Gazette*, either bound or single copies, prior to 1935? We are anxious to have complete files, at least back to 1925. If any one would donate or sell us back numbers, we should be most grateful. In either case the College would pay postage. Please communicate with the Librarian.

Yours, etc.,

J. DONALD BALL, M.B.
M.R.C.P. (Lond.),

Actg. Medical Superintendent.

CHRISTIAN MEDICAL
COLLEGE, VELLORE.

GROUNDNUT CAKE FOR HUMAN CONSUMPTION

SIR,—I am writing to express my delight on seeing that, with Dr. Daver's article in the May 1947 issue, the *I.M.G.* has taken up the cause of groundnut cake flour for human consumption. I consider this a matter of greatest national importance and hope that you will continue to champion this cause with the full weight of the scientific authority of which the *I.M.G.* is a mouthpiece. Though I have hitherto refrained from emerging into scientific print, I have during the last four and a half years been intensively occupied with the subject. During this time I have, largely in vain, tried to create an appreciation of the fundamental importance of the nutritional and economic questions involved.

Mixed with cereals or pulses in proportions as suggested by Daver the 'nutty' flavour of edible groundnut cake is practically imperceptible. In numerous experiments in which such mixtures were offered as food to persons who did not know the composition of what they were eating it was not once detected. Regularly such persons—and they were from every walk of life—when offered the plain and the nut flour containing preparation claimed to prefer the latter. So much for the 'smell'.

The common belief that groundnut cake produces diarrhoea is based on 3 different facts of which Daver mentions one—the adulteration in an unclean press with castor oil. The second reason is that during a temporary food shortage the ordinary commercial cake is sometimes eaten. This definitely produces diarrhoea owing to an adulteration of the cake with fragments of the outer shell and hard grit which the miller adds in order to get a better 'grip' in his expeller and consequently an higher yield of oil. These hard sharp-edged particles set up a mechanical irritation in the bowel. Diarrhoea never occurs when clean kernels only are used. Finally, if whole nuts are consumed in large quantities as during the harvesting season by persons whose fat digestion is impaired owing to a lack of vitamin B, particularly nicotinic acid, a sudden excess of vegetable fat may lead to diarrhoea. This, of course, does not apply to the cake from which most of the oil has been removed.

There can be no doubt whatsoever that by every known scientific standard edible groundnut cake is the finest all round human vegetable food produced in this country, with the special advantage of being so incredibly rich in high-grade protein (50 per cent as compared with mutton's 35 per cent) that it is just what is needed in a country where protein deficiency is the outstanding feature of malnutrition. The groundnut proteins have, according to Dr. B. G. S. Acharya, who very kindly conducted rat feeding experiments in the Garutman Laboratories, Bombay, at my request, a very high digestibility coefficient (91.44). With about 7 per cent fat, 31 per cent carbohydrates and a high mineral and vitamin content groundnut cake is a beautifully balanced food with which to enrich cereals and pulses. In spite of its high protein content it has the same caloric value as wheat and jowar.

That this superfood is used in an underfed country as a fertilizer to produce sugarcane and other money crops seems utterly incomprehensible. Plants can assimilate and thrive on inorganic chemical fertilizers which we cannot; they can feed on dung which we cannot. Why then feed them with potential human food? We cannot digest cotton seed, cattle can. Yet we feed our cattle with large quantities of what we might eat ourselves, with a perfect, ready-made, human food in order to induce them to transform a small fraction of the offered nut protein into milk protein and a little perfectly good vegetable fat into animal fat in the form of butter. This is a ruinous and wasteful luxury which even the richest and best-fed country should hesitate to allow and which in India can only be described as suicidal.

A ton of groundnut cake is equivalent in protein food value alone to a flock of 50 sheep, to 50,000 eggs, to 15,000 seers of milk and India produces annually about seven lakhs of tons. A farmer who ploughs a ton of groundnut cake into his field is actually burying enough protein to cover all the requirements of his family for a whole year. He might with as much sense of nutritional economy slaughter and bury his goats and sheep and pour all the milk his cows produce on his fields to grow tobacco. In addition to the proteins, ready-made fats, starch, vitamins laboriously prepared by the groundnut plant are buried only to be broken down again into the simple chemicals the plants can utilize. This sheer waste of biological energy is stupendous.

We read and hear much about food yeast and the soya bean. The one requires an industrial plant and the other good land, neither are now produced on a large scale while huge quantities of groundnut cake which would serve an identical purpose are already available. With some minor changes in processing it can be made edible. It is also cheap and its use for human food would in no way dislocate the oil industry, in fact, it would improve it.

The sudden opening up of this new source of cheap high-grade protein, mineral and vitamin food would undoubtedly have a profound influence on the nation's nutrition, its health and its vital statistics.

Yours faithfully,

A. T. W. SIMEONS, M.D.

BOMBAY.

PROGRESSIVE MUSCULAR ATROPHY

Sir,—Reference to my letter about a case of 'Progressive muscular atrophy' in your April number, page 241.

The only further symptom, during these few weeks, has been :—

Mild pains in the deltoids (alternately) and in the extensor muscles of the head. Injections of strychnine gr. 1/20 and vitamin B, 50 mg. every three or four days are continued, apparently doing much good.

Yours faithfully,

A. OMAR.

GONDA, U. P.,
13th August, 1947.

Any Questions

NOVOCAINE TREATMENT OF OSTEOARTHRITIS

Sir,—I am giving below a copy of an article I came across in *News Review*.*

Will you very kindly let me know if to your knowledge and experience intravenous administration of novocaine affords relief in arthritis. If so, please let me know in what strength the novocaine has to be administered and what types of arthritis are liable to be benefited the most.

I am, etc.,

H. C. JAIN, M.B., B.S.

CHANDAN NIWAS,
AJMER.

A way to relieve the crippling agonies of arthritis has been discovered by Drs. Joseph Kovacs and David Granband of New York Reconstruction Hospital. Their method is to give intravenous injections of novocaine one, two or three times a week according to the form of the disease and the state of the patient.

Cautions by the doctors say that the treatment is no more a cure for arthritis than aspirin for the causes of headaches. Moreover, unless the drug is administered with great care, the patient is liable to get convulsions.

But their discovery has value. Relief of pain is an important stage in the treatment of arthritis. It gives the patient more mobility and brighter mental outlook. Startling and gratifying is how the doctors describe their success in dimming the pain.

[Ernest Fletcher in his 'Medical disorders of the locomotor system' (E. and S. Livingstone Ltd., Edinburgh, 1947), page 336, mentions the novocaine treatment of osteoarthritis as follows :—

'Novocaine (procaine) has been used as a joint injection in a great many cases. The usual strength is $\frac{1}{2}$ per cent and the quantity for a knee is 10 c.c. There is no doubt that pain is entirely relieved for a period. The duration of this period varies from four hours to a day. Succeeding injections as a rule are followed by prolonged periods of freedom, and in a very large number of cases, the pain may cease entirely for months. A good plan is to continue the injections, after the pain has been relieved, once every month or six weeks. Naturally enough the rationale is not understood, but the result attained follows the pattern obtained in other parts of the body, where the temporary interruption of pain sensation may in fact become permanent or semi-permanent, although the original pathological stimulus is not affected. It matters little from the point of view of treatment whether the explanation is really of a psychological character.'—Editor, *I.M.G.*]

DHATURA STRAMONIUM SEEDS IN WHEAT

Sir,—Could you answer the following :—

1. Is a stock of wheat containing up to 0.6 per cent dhatura stramonium fit for human consumption?
2. What is the minimum percentage of this seed which should render the wheat unfit for human consumption?

Yours, etc.,

R. B. LAL.

ALL-INDIA INSTITUTE OF HY-
GIENE AND PUBLIC HEALTH,
CALCUTTA.

[Taking the average consumption of wheat per head to be 250 gm., the total quantity of dhatura stramonium seeds contained at the rate of 0.6 per cent will be 1.5 gm. or 1/20 grain of the alkaloids (0.186 per cent of the seeds). This amount is three times the therapeutic dose which is 1/240 to 1/60 grain. The wheat is thus not fit for human consumption.—J. C. G.]

* Relief for arthritis, *News Review*, 5th June, 1947, page 19, column 4.

PENICILLIN IN TUBERCULOSIS OF LUNGS AND JOINTS

SIR,—Please discuss the use and contra-indications of penicillin in cases of tuberculosis of lungs and joints in your journal.

Yours, etc.,

M. ABDULLA, L.C.P.S., L.M.S.

THE NURSING HOME,
VANIYAMBADI
(NORTH ARCOT).

(Penicillin has not been found to be of much use in the treatment of diseases caused by *Mycobacterium tuberculosis*.—A. C. U.)

Service Notes

APPOINTMENTS AND TRANSFERS

COLONEL K. S. MASTER, M.C., K.H.P., is appointed Colonel Commandant of the Indian Army Medical Corps.

On return from one month's leave, Colonel L. K. Ledger, C.I.E., O.B.E., assumed charge of the office of the Inspector-General of Civil Hospitals-cum-Director of Public Health, C.P. and Berar on 11th June, 1947, and Lieutenant-Colonel A. S. Garewal, Inspector-General of Prisons, C.P. and Berar, ceased to hold the additional charge of Inspector-General of Civil Hospitals, C.P. and Berar, from the same date.

The Viceroy and Governor-General has been pleased to make the following appointments on His Excellency's personal staff :—

Honorary Surgeons

24th March, 1947

Colonel V. N. Agate.	Colonel J. R. Kochhar.
Colonel E. Cotter.	Colonel S. M. A. Faruki.
Colonel D. Clyde.	Colonel S. L. Bhatia, C.I.E., M.C.

LEAVE

Captain T. P. Publishers' Notice

SCIENTIFIC Articles and Notes of interest to the profession in India are solicited. Contributors of Original Articles are entitled to receive 25 reprints *gratis*; additional reprints can be obtained on payment. No reprints will be supplied unless contributors ask for them at the time of submitting their manuscripts.

The preparation of reprints entails rearranging the type, so that there is often a delay of a month or more, after the publication of the *Gazette*, before the reprints are ready. If reprints are not received within two months of publication of the *Gazette*, contributors should write to the Publishers.

Papers and articles forwarded for publication are understood to be offered to *The Indian Medical Gazette* alone, and any breach of this rule will be followed by non-publication. When any such article appears in *The Indian Medical Gazette*, the copyright automatically becomes the joint property of the author or authors and of the publishers.

Communications on Editorial Matters, Articles, Letters and Books for Review should be addressed to THE EDITOR, *The Indian Medical Gazette*, c/o The Calcutta School of Tropical Medicine, Central Avenue, Calcutta.

Communications for the Publishers relating to Subscriptions and Advertisements should be addressed to THE PUBLISHERS, *The Indian Medical Gazette*, P. O. Box No. 54, Calcutta.

Annual Subscription to '*The Indian Medical Gazette*', Rs. 16 including postage, in India. Rs. 19-8 including postage, abroad. Single copies Re. 1-8 each. Back numbers (if available) for the previous year Rs. 2-8 each, and all other back numbers Rs. 5 each.

The Editors of *The Indian Medical Gazette* cannot advise correspondents with regard to prescriptions, diagnosis, etc., nor can they recommend individual practitioners by name, as any such action would constitute a breach of professional etiquette.

TREATMENT OF RELAPSING MALARIA WITH SPECIFIC ANTIMALARIAL DRUGS IN COMBINATION WITH PENICILLIN

By P. L. DESHMUKH, M.D. (Bom.),
D.T.M. & H. (Lond.), F.C.P.S.
Sassoon Hospitals, Poona

It must be admitted that even with quinine and the synthetic antimalarial drugs like atabrine, mepacrine, etc. (henceforth called 'specific antimalarials' for the sake of brevity) the treatment of malaria is still very unsatisfactory. The recognized failure of the specific antimalarials singly or in combination to control the relapses materially is a matter of great concern. A great variation is observed in the interval that may elapse before the occurrence of a relapse. The period is known to extend from a few days to several years, but for all practical purposes it is taken as four months. Sometimes in the absence of a relapse the infectivity of the blood is demonstrated after many years by the appearance of malaria in a person transfused with the blood of a once malarial patient (*Jewish Med. Assoc.*, 1945). Professor Adler of Palestine is of opinion that, 'Plasmodium once acquired cannot be got rid of, a fact on which amount of quinine administered has no bearing'.

It is, sometimes, difficult to check acute exacerbations of malaria with the specific antimalarials. This is attributed to the difference in the strains of the plasmodium, some being more resistant to the specific antimalarials. This resistance may be natural or acquired. Some strains may be perhaps more virulent than others. The difficulty becomes greater when pregnancy complicates malaria.

The toxicity of the specific antimalarials when used in full doses over long periods also presents a problem in the treatment which cannot be ignored. The magnitude of the problem can be assessed from the numerous clinical reports of toxic effects of antimalarial drugs in the medical journals.

The general dissatisfaction with the specific antimalarials has served to emphasize the importance of developing new methods of treatment in malaria. Below we shall discuss some of them briefly.

Treatment of malaria with arsenicals, singly or in combination with the specific antimalarials, is believed by many as a definite advance in the treatment (*Stewart*, 1945; *Dao*, 1945). The writer was also, in the earlier part, greatly impressed by the treatment when he found on several occasions that it was able to check the acute attacks quickly when the specific antimalarials alone failed to do so or did not come

up to the expectation. But it soon became clear that they did not control relapse, and also that they carry with them a danger of toxicity. Arsenic is notorious for causing damage to liver, kidneys and brain. When pregnancy complicates malaria, the use of quinine and arsenic may be particularly risky and one is on the horns of a dilemma as regards the satisfactory treatment in such circumstances.

The writer's experience of arsenicals in malaria has been borne out by other workers and their findings in large-scale experiments given below will help to dislodge from the minds of the clinicians any lingering faith in arsenic as an ideal antimalarial drug.

Professor Blacklock (1944) has pointed out after long studies at the Liverpool school that though the immediate effects of arsenic in relapsing malaria were striking, the ultimate results were disappointing in that practically all cases relapsed even after full arsenical treatment. Thus, arsenicals though immediately effective against vivax parasites do not eliminate the liability to relapse. It is also important to recognize that the effect of intravenous arsenic is entirely confined to vivax infection; so that, its usefulness in treatment is limited. 'Arsenicals may have a use in special cases but would appear to find little place in routine treatment'.

Kay (1945) reports 67 cases treated with atabrine and mapharsen combination. There was a relapse of 71.6 per cent cases and the mean time of relapse interval was shorter than with atabrine alone. Thus, mapharsen is of no practical value as an adjuvant to atabrine in the treatment of relapsing tertian malaria.

The remarkable activity of the sulphonamide compounds in bacterial infection led to their being tried in malaria. After experience with prontosil (*Editorial*, 1939), Niven concludes that 'although prontosil has lethal action on the malarial parasite it has no place in practical treatment of malaria, owing to its low efficiency, possible toxicity and relatively high cost'.

The suggestion that sulphonamide derivatives might be able to prevent relapse in malaria where the infection is already clinically suppressed by a previous course of one or more of the specific antimalarials, encouraged Coggeshall and others (1945) to try sulphadiazine, in the army. They treated 33 patients of vivax infection with sulphadiazine for two months immediately after the clinical symptoms were controlled by the specific antimalarials. Follow-up three months later showed 16 or 48.5 per cent had relapsed, thus demonstrating that sulphadiazine has no value in preventing relapses in vivax infection.

Coxon and Hayes (1946) treated 20 cases of malaria with sulphadiazine with relapses in one month.

Recently, Gross (1947) has suggested the use of male hormones for the prevention of relapses in malaria. The rationale on which he bases the treatment appears far from convincing. I

have no experience of his treatment but I seriously doubt whether the treatment will be advisable in female patients in view of the possible hormonal effects on the secondary sexual characters.

Recent world war has given a great impetus to the research in the therapeutics of malaria. Difficulty to cure the Pacific vivax infection was very disconcerting, and new chemicals came on the field for clinical trial. Following are some of them: *Chloroquine*. It was found to be less toxic and more effective than quinacrine against the plasmodium. It is useful in curing the falciparum infection, but in the case of vivax, it only tends to prolong the interval between relapses. Thus, though it is superior to quinine and quinacrine as an antimalarial drug in acute attack, it fails to control the relapses due to vivax. *Pamaquine*. This drug is believed to be useful in curing vivax infection. But the therapeutic dose is so close to the toxic dose that it is dangerous to use it in routine practice. *Pentaquine*. This is closely related to pamaquine chemically. It is as effective as and less toxic than the latter and holds a good promise to lead to even a still less toxic drug which may be useful for routine treatment. *Paludrine*. It is too early to express an opinion on the efficacy of this drug but it is believed that it will not control vivax relapses materially.

It is generally believed that the more thorough the treatment of the acute attack by the specific antimalarials, the less likely is the occurrence of the relapses. This assumption is not justified by the experience of Hughes and Bomford (1944) in West Africa. They treated a series of 1,200 cases in the army 'thoroughly' with the specific antimalarials and after a follow-up they report that 'the return cases were no less numerous than anyone else's even after a "thorough" treatment'.

Another prevalent belief is that relapses can be avoided by the constant use of atabrine or quinine. Such a use of the specific antimalarials, after all chances of re-infection are excluded, will only insure freedom from clinical symptoms as long as taken. They do not cure. If relapses cannot be controlled, the rational therapy should consist of treatment of relapses as they occur rather than continuous suppression by medication. Thus, there is yet no drug or method of treatment that can be relied on to terminate the malarial infection.

With a view to finding a treatment that will check the acute attack and also control the relapses the writer decided to try the effect of quinine in conjunction with the antibiotic penicillin. Penicillin is shown to have no action on inoculation (Hindle *et al.*, 1945) malaria and plasmodium is believed to be insensitive to penicillin, still the choice of penicillin for therapeutic trial was guided by the fact that its potentialities are not yet completely known. It was thought that though it may have no effect on the peripheral parasites, it may show

some action on the mysterious cycle of the parasite in the internal organs. In all 6 cases were treated with success on this line of treatment. The following is the report of two typical cases so treated:

Case 1

Mrs. S. J., aged 35 years, four months' pregnant, came under observation for fever with rigors of 15 days' duration. The fever rose every day to 103 to 104°F. with rigors and came down with profuse perspiration. There was a history of similar attacks one year back. Before coming under observation, she was reported to have been treated during this attack by two injections of quinine and yellow tablets probably mepacrine. A blood film taken during the rigor showed 2 to 4 parasites in each field in various stages of development, denoting clearly that the treatment given was not able to suppress the infection and check the acute bouts. Spleen was enlarged two fingers. She was very anæmic so much so that a few steps made her breathless. The rapid development of anæmia can be judged from the fact that 15 days back she was well and working. An injection of quinine bihydrochlor gr. vi was given in one buttock and two lac units of penicillin in 6 c.c. of normal saline were given on the other buttock, intramuscularly, in the morning. The temperature rose only to 100°F. that evening and came down to normal in two hours. Next morning only the dose of penicillin was repeated. There was no rise of temperature that evening. Third morning both quinine and penicillin were repeated as on the first day. For the next 5 days mepacrine tablets were given twice a day. None of the drugs were repeated thereafter. Further treatment consisted only of iron mixture and liver extract injections to combat anæmia. Blood films examined at fortnightly intervals did not show any parasites. There is no recurrence of fever to the present day, i.e. four months after.

Case 2

Mr. S. V. K., aged 24 years, came for repeated attacks of fever with rigors for the last six months off and on. The fever was checked every time by the specific antimalarial drugs. When he came under observation he had enlarged spleen, anæmia and his blood film showed benign tertian infection. He was treated with injections of quinine and penicillin and mepacrine tablets as in the previous case. For the last three months he has no recurrence of fever and the blood film does not show parasites.

Four other cases were treated similarly but have been followed only for six to eight weeks without a relapse.

Discussion

It is very premature to draw conclusions of a definite nature from the meagre clinical

material presented here. However, it will be found to be fairly informative regarding the prospects of this combination treatment in the control of malarial relapses. It will, at least, be considered as deserving a trial in a larger series of cases. In case 1, the outstanding feature was the early control of the acute attack which was not checked by the previous treatment with injection of quinine and probably mepacrine tablets. It clearly appeared that penicillin had a synergic effect on quinine in terminating the malarial cycle once for all, and preventing relapse in the next four months at least. It also became possible to suppress the infection with only a small dose (gr. xii) of quinine with the help of penicillin as it was feared that quinine in larger doses would exert an abortive effect.

Case 2 clearly illustrates the influence of the combination treatment on the control of relapses in particular.

Mechanism of relapse and the probable action of penicillin

The problem of control of relapse will be greatly elucidated if we are able to formulate our conception regarding its mechanism. Experiments in avian malaria have tended to modify the theory of malarial cycle. According to the modern concept (National Med. Congress, 1946) the cycle of the parasite in the human host is far more complicated than the simple invasion of the red blood cells. Fairley has shown that the sporozoites disappear from the blood stream in 30 minutes after inoculation by the mosquito to reappear in the peripheral blood on the ninth day and regularly thereafter. Thus, there appears to be a pre-erythrocytic stage in which the parasites invade the endothelial or mesenchymal tissue cells where, it is presumed, they undergo a distinct cycle of development before they are discharged in the blood stream. In blood they begin the so-called erythrocytic cycle. The persistence of the infection in the mesenchymal cells essentially contributes to the recurrence of malaria. Thus, the mechanism of the relapse can be explained by the periodic discharge of parasites in the peripheral blood from the fixed tissue cells. The mesenchymal tissue of healthy persons is strong enough to have plasmodia constantly captive. But as soon as the resistance of the individual lowers, the hold of the mesenchymal tissue on the plasmodia becomes weaker with their consequent escape in the peripheral blood to bring on a recurrence of malaria. This theory explains a number of problems that are encountered in the study of malaria.

It explains the variation that is observed in the relapse rates of the tertian and malignant forms. *Falciparum* malaria, if well treated in the acute stage, does not tend to relapse while *vivax* infection is notorious for its liability to relapse (Editorial, 1946). A short term of development in fixed tissues with complete

delivery of parasites in the blood would lead to a short-term infection, as in *falciparum*. Conversely, a prolonged period of development in fixed tissues with partial expulsion of parasites in the blood stream, would lead to a relapsing infection, as in *vivax*.

The new concept also explains why even a 'thorough' treatment of the acute attack is not able to prevent relapses. The specific anti-malarials which are commonly used act only or mainly on the erythrocytic stage of the parasite. The mesenchymal cycle is unaffected though the peripheral blood may be cleared of parasites. Thus the usual antimalarial treatment, however 'thorough', is not able to de-infect the fixed tissue cells and thus to prevent the invasion of the erythrocytes in the peripheral blood. Some drugs like pamaquine, paludrine, etc., are believed to act also on the pre-erythrocytic stage of the parasite and hence their relative efficacy in the control of relapse.

The control of relapse when penicillin is used in conjunction with the specific antimalarials can be explained by assuming that penicillin has an anti-parasitic action on the pre-erythrocytic stage of the parasite either directly or indirectly by affecting the metabolism of the mesenchymal cell which lodges the parasite ('host-cell' or 'lodger-cell').

The theory will explain the appearance of clinical malaria soon after the suppressive therapy is suspended, and the late primary manifestations after prolonged prophylactic suppressive measures.

Unfortunately, conclusive evidence of the pre-erythrocytic stage in man is still to be found though there is much to support the postulation of its existence. If our claims for usefulness of the combination treatment for control of relapses are supported by our further work and that of other workers in the field, the problem of relapsing malaria will be solved once for all with rational therapy.

Conclusions

From the scanty clinical material available it is presumed that penicillin has a synergic action on quinine in the control of acute attacks of malaria. Penicillin is also believed to have a selective action on the assumed pre-erythrocytic stage of the malarial parasite. The use of penicillin in conjunction with quinine and mepacrine is believed to be useful in controlling the acute attacks quickly and the relapses in the future. The treatment is based on the rationale that the usual specific anti-malarials control the erythrocytic stage and penicillin controls the pre-erythrocytic stage of the malarial parasite.

Summary

Attempts and their futility to discover a treatment to control relapses in malaria so far, are mentioned from literature. Taking advantage of the new concept of malaria cycle in man, a

combination treatment of malaria with quinine, mepacrine and penicillin is suggested which may be adequate to control the acute as well as the relapsing course of malaria. A report of two from the six cases treated on this line is given in full.

CLINICAL FEATURES OF MURINE TYPHUS

By B. BHATTACHARJYA, M.B., B.S. (Pat.),
 M.R.C.P. (Lond. & Edin.), D.P.M.
 MAJOR, I.M.S./I.A.M.C.
 C. M. H., Secunderabad

BETWEEN the middle of October 1946 to the middle of January 1947, 11 cases of typhus fever were admitted in C. M. H., Secunderabad. Seven of these cases were diagnosed as murine typhus.

The cases occurred in a camp, about 80 miles from the town; those of murine typhus, came from sections B, C and D of the camp. These

Clinically the cases will be described here in 2 groups.

Group A.—Four cases of proved murine typhus with positive Weil-Felix reaction and complement-fixation test.

Group B.—Three cases with distinctive clinical features of murine typhus, including rash and positive Weil-Felix reaction in one case.

Group A

The onset was fairly sudden but not severe; it was characterized by rigor (2), headache (2), cough and chest signs (3), pains and aches in the body (2).

The pain in the chest and moderate cough developed early in the course of the disease.

The fever was of remittent type, with the evening temperature 2 to 3°F. higher than the morning one. The average duration of pyrexia was 11.25 days. It ended by lysis. Tongue was usually coated and dry (see temperature charts 1 to 4).

The pulse rate showed relative bradycardia in proportion to the temperature and the respiratory rate varied in direct proportion to the temperature.

The rash was not a constant feature. It appeared in two cases. In case (1), it was noticed on the 7th day of fever, over the extremities, spreading later to the trunk, soles and palms. Face was exempt. In the early stages, the rash was of a macular type; showed transient fading on pressure. In the later stages, it became petechial. The rash disappeared 6 days after subsidence of pyrexia and left a staining behind. In case (3), faint macular rash appeared on the chest on the 3rd day; spread to the trunk and faded on the 6th day.

There was no adenitis in any of the cases, nor was the spleen or the liver palpable.

Temperature charts of four typical cases of murine typhus.

sections were surrounded by agricultural land and rocky ground with scattered bushes. There were two villages very near the camp, one between B and C, and the other between C and D. It is possible that the infection was acquired in the villages. The epidemiologic aspects are under investigation by the Field Typhus Research Team.

Chest signs.—Physical findings varied from bronchitis to that of pneumonitis with impairment of percussion note over the bases, especially over the left base. Radiological findings were indefinite and varied: case (2), faint mottling of lung fields, case (3), increased density over the bases and case (4), increased density over left mid and lower zones.

Weil-Felix reaction OX19—1/640 to $\frac{1}{10,240}$ (3 cases). OX2—1/2560 (1 case).

Complement-fixation test against murine typhus was positive in all the four cases in titres 1/20 to 1/40.

Leucocyte count varied from 6,000 to 12,000 per c.mm. with more than 70 per cent polymorphs.

Blood culture and widal tests were negative.

Complications.—Two cases had acute mental symptoms, e.g. delirium, euphoria; behaviour abnormality. One case had epididymitis.

Average stay in hospital—40 days, longest being 70 days and shortest 23 days.

No fatality.

Case notes

(1) Gnr. C. L., B.O.R., age 32; onset of disease on 2nd November, 1946. Admitted on 5th November, 1946, presenting symptoms—fever, rigor, headache and cough. Duration of fever 16 days. Rash appeared on the 7th day of illness; macular at first, later petechial; distributed over the whole body, including palms and soles; face exempt. Rash lasted for 15 days and left a staining.

Weil-Felix reaction—	18-11-46	24-11-46	13-12-46
OXK	0	0	0
OX19	1/640	1/320	1/40
OX2	1/2560	1/1280	1/640

Complement-fixation test 1/40 (24-11-46)
(against murine typhus).

(2) Swr. M. N., I.O.R., age 23; onset of disease on 2nd January, 1947. Admitted on 4th January, 1947, presenting symptoms—fever, cough and pain in the chest. Duration of fever 10 days. No rash. Chest—diminished breath sounds in both bases. X-ray chest—faint mottling, both lung fields.

Weil-Felix reaction—	4-1-47	15-1-47
OXK	1/40	1/40
OX19	1/640	1/640
OX2	1/320	1/640

Complement-fixation test 1/40 (15-1-47)
(against murine typhus).

(3) L/Nk. K. H., I.O.R., age 25; onset of disease on 11th January, 1947. Admitted on 13th January, 1947, presenting symptoms—fever with rigor and cough; duration of fever 8 days. Rash appeared on the 3rd day of illness; macular type; distributed over the trunk only; lasted for 3 days and left no staining. Other features in this case were nerve deafness; marked bradycardia with dicrotic pulse; drowsiness

followed by acute mental symptoms; during convalescence developed acute epididymitis.

Weil-Felix reaction—	25-1-47	30-1-47	13-1-47	21-1-47
OXK	0	0	0	1/20

OX2	1/320	1/160	0	0

Complement-fixation test 1/20 (30-1-47)
(against murine typhus).

(4) Captain P., age 26; onset of disease on 22nd January, 1947. Admitted on 23rd January, 1947, presenting symptoms—fever with pain all over the body, cough and headache. Duration of fever 11 days. No rash. Chest x-ray 'increased density mid and lower zones of left lungs'.

Weil-Felix reaction—	23-1-47	6-2-47
OXK	0	0
OX19	1/640	1/10240
OX2	1/160	1/40

Complement-fixation test 1/40 (6-2-47)
(against murine typhus).

Group B

Three cases had clinical symptoms more or less similar to group A cases, e.g. remittent pyrexia—average duration 15 days; dry coated tongue, bradycardia, rash over the trunk; no glandular or splenic enlargement; acute mental symptoms (2 cases); agglutination against OX2 in high titre (1 case). Complement-fixation test was not done in these cases. They probably were also cases of murine typhus.

Case notes

(1) Gnr. K. J., I.O.R., age 23; onset of disease on 25th October, 1946; date of admission 29th October, 1946; duration of fever 12 days presenting symptoms—fever with headache, pain in the body and cough. Rash appeared on the 5th day; maculo-papular in type and distributed over the trunk; lasted for 5 days and left no staining. This patient had symptoms of acute toxic psychosis.

Weil-Felix reaction—	2-11-46	6-11-46
OXK	0	0
OX19	1/20	1/80
OX2	1/80	1/2560

(2) H/C. M., I.O.R., age 33; onset of disease on 8th November, 1946; admitted on 13th November, 1946; presenting symptoms were fever with rigor and joint pains. Fever lasted for 17 days. Macular rash appeared on the 7th day; was distributed over the whole body, palms and soles being exempt. The rash faded after 7 days, leaving a staining behind. Symptoms of

acute mental confusion appeared during the course of the disease.

Weil-Felix reaction—	14-11-46	22-11-46	27-11-46
OXK	1/20	1/20	0
OX19	0	0	0
OX2	0	1/20	1/80

(3) Dvr. C., I.O.R., age 22; onset of disease on 1st December, 1946; admitted on 5th December, 1946; presenting symptoms were fever with pain all over the body; duration of fever 16 days. Rash appeared on the 11th day at first macular in type, later became papular. It was limited to the trunk only and faded after 12 days, leaving a faint stain behind.

Weil-Felix reaction—	12-12-46	17-12-46	24-12-46
OXK	0	0	0
OX19	1/40	1/80	1/80
OX2	0	1/20	1/20

Conclusion.—Seven cases of fever diagnosed as murine typhus are described. Cases in groups A and B had similar clinical features, with a remittent pyrexia, furred tongue, bradycardia, and presence of rash of varying severity in some cases. In group A cases, diagnosis of murine typhus was established by Weil-Felix reaction against either OX19 or OX2 in high titre and complement-fixation test against murine typhus. Group B cases had rash (3) and positive Weil-Felix reaction (1).

I am indebted to Major S. L. Kalra, I.A.M.C., of Field Typhus Research Team for many valuable suggestions.

SCRUB TYPHUS: VARIATIONS IN CLINICAL SYMPTOMS AND STRAINS

By S. LAL KALRA

THE object of this short paper is to point out certain symptoms peculiar to certain places and present laboratory evidence of the variation of the rickettsial strains which one considers to be the cause of difference in the severity and symptoms of the disease.

The entry of the forces in large numbers in the eastern zone of war not only brought to light the presence of scrub typhus in unrecorded areas, but also interesting information about its clinical variations in different countries and in different parts of the same country. The local population in endemic areas generally acquires immunity by mild attacks during childhood and does not provide evidence of the disease. It is also well known that the disease in children is mild and has low mortality rate and reverse is the case in older people. Lewthwaite and Savoir (1940) in Malaya have recorded two deaths out of twenty-five in patients under eighteen and 4 out of 20 in those over forty

years of age. The experience in this war was that the fatalities were higher in the age group thirty-five years and over as compared to the age group below it. The information obtained during this war is important, for it is based on the incidence of the disease in a non-immune population more or less of the same age group in different areas.

Clinical

Considering mortality rate as one of the criterions of the severity of a disease, different areas fall into two categories, those with a mortality rate of 0 to 3 per cent and others of 8 to 12 per cent (table I). There are hardly any areas which fall outside these limits. Japan where the mortality rate is said to be over 20 per cent or over is excluded as only pre-war records were available.

TABLE I

Force	Place	Number of cases	Deaths	Mortality rate, per cent
British ..	Addu Atoll and Diego Garcia.	100	1	1.0
Indians ..	Addu Atoll	1,056	24	2.4
" ..	Diego Garcia	85	0	0.0
" ..	Ceylon	20	0	0.0
British ..	Ceylon	64	0	0.0
E. Africans	Ceylon	713	13	1.8
Indians ..	Meiktila-Burma	40	0	0.0
" ..	Mandalay-Burma	130	13	10.0
" ..	Moreh-Burma	35	4	11.4

Mandalay.—The mortality rate in this area was 10 per cent. Majority of the cases were very toxæmic. The particular symptom was tympanites which occurred in 30 cases out of 80. The condition was distressing to the patient and difficult to relieve.

Meiktila.—The disease was generally mild, no case was toxæmic and there were no fatalities. This area is at a distance of 110 miles only from Mandalay.

Kalewa.—The infections here also ran a mild course and there were no deaths. Inflammations of the parotid glands occurred in two cases early during the course of the fever.

Moreh (Imphal-Burma border).—The cases in this area were drawn from both sides of the border. The mortality rate was 9 per cent. Some cases were so mild that they sought hospitalization 7 to 10 days after they had been febrile. In these cases there was hardly any toxæmia, there were no serious symptoms or complications, but the febrile period was prolonged to four weeks which was longer than in serious cases. In Ceylon (*vide infra*) the febrile period was increased by lung complications, but here there were no complications to account for it.

In severe cases there were marked daily fluctuations in the temperature in the first ten days, delirium was common and in fatal cases the death occurred in the second week. On post-mortem examination in two cases there was hæmorrhage in the sheath of the rectus muscle spreading downwards into the recto-peritoneal tissue, and in the other two cases free fluid was present in the pericardial sac, besides the usual pathological changes present in a case of scrub typhus.

Ceylon.—The early symptoms in a vast majority of cases were marked enlargement and tenderness of the cervical lymph glands which rendered all neck movements painful and produced false rigidity. Movements of the eye balls were also painful, there was suffusion of the eyes and drowsy look. These symptoms produced such a typical rigid expression that spot-diagnosis was unmistakable. This combination of early symptoms with such a regularity was not seen in any other area. The disease otherwise was rather mild and complications were few. There were only odd cases of delirium, tracheitis, broncho-pneumonia, epistaxis and renal failure. The duration of fever in most of the cases was less than three weeks and prolongation of this period was generally due to lung complications. There were no fatal cases in British and Indian troops and the mortality rate in East Africans was 1.8 per cent.

Addu Atoll (Maldiv Islands).—The incidence of the disease was very high reaching 49.5 per thousand per month in August 1942, but the symptoms were typical of a mild attack. Pneumonitis was the only common symptom in every case. The mortality rate was 2.4 per cent in Indian troops and 1 per cent in British troops. Some of the cases died of sudden heart failure during convalescence. One case while convalescing in his unit lines developed acute meningococcal septicæmia and died within twenty-four hours.

Experimental evidence

Cross immunity and one way immunity experiments were carried out on rabbit's eye with some of the *R. orientalis* strains isolated from different areas. The results showed that while strains from different sources from the same area gave complete cross protection, strains from different areas failed to do so.

R2 strain from Paungde in Burma gave no cross immunity against E strain from a patient in Kalewa and D2 strain from mites from Palel (Imphal), while E and D2 strains gave complete cross protection against each other.

Another rabbit immunized with R2 strain was re-inoculated in the other eye, six months later, with a strain from Bhim Tal (Kumaon hills) and developed a non-immune reaction.

R2 strain always produced a severe reaction in the eye of the rabbit as contrast to a strain (Bi) from Tamu, which always produced a mild reaction. The disease in Tamu from where the strain was recovered was also generally mild.

A rhesus monkey that had been twice inoculated with Imphal strains reacted like a non-immune animal to R2 strain developing marked fever and lymphopenia.

When a Kumaon mite strain and a Kumaon rat strain were tested against Ceylon strain the mite strain produced a reaction but the rat strain did not.

Conclusions

From the above evidence one can conclude that even in different parts of the same country the disease may be mild with low mortality rate of below 3 per cent, or severe with high mortality rate of 8 to 10 per cent.

There are variations in particular symptoms from place to place although the symptoms in any one district are usually consistent and one considers that this is due to variations in the virulence and other qualities of different strains.

TABLE II
Intra-ocular tests on rabbits

Immunizing strain	Incubation period, days	Duration of reaction, days	Challenge strain	Incubation period, days	Duration of reaction, days
E-Kalewa ..	7	20	R2-Burma	10	18
R2-Burma ..	10	22	E	8	20
D2-Imphal ..	14	26	R2	6	17
R2 ..	10	22	D2	19	26
E ..	9	15	D2	..	No reaction
D2 ..	7	24	E	..	No reaction
Ceylon ..	15	6	M-Kumaon	6	18
..	10	22	R-Kumaon	..	No reaction
B2-Imphal ..	11	23	* M-Kumaon	..	No reaction
R2-Burma ..	9	24	* R-Kumaon	19	No reaction

*The challenge dose was given six months after the first inoculation.

Diego Garcia (Chagas Archipelago).—There were 85 cases in Indian troops with no complications and no fatality.

SULPHADIAZINE IN THE TREATMENT OF CHOLERA

By C. L. PASRICHA

LIEUTENANT-COLONEL, I.M.S.

Director, School of Tropical Medicine

B. M. PAUL

A. C. DAS GUPTA

and

A. K. DAS

(From the Cholera Treatment Unit, Indian Research Fund Association, School of Tropical Medicine, Calcutta)

CHU AND HUANG (1946) used sulphadiazine in 10 cholera patients with 10 other patients as controls. The average duration of diarrhoea of the sulphadiazine-treated patients (4.6 days) was shorter than that of the controls (7.1 days) and the total amount of saline required was less in the sulphadiazine-treated cases than in the controls. Chu, Huang, Chang and Kao (1946) report the treatment of 25 cases of cholera with sulphadiazine and compare the result with that of 29 cases not treated with sulphadiazine and claim efficiency for sulphadiazine on clinical data.

The results of treating a larger series of cholera patients with sulphadiazine* as compared with the results of a parallel series not treated with sulphadiazine are presented in table I.

All the patients were suffering clinically from cholera and were treated as in-patients in a cholera hospital. The selection of cases for treatment was made on alternate admission basis. In many, the diagnosis was confirmed by the isolation of agglutinable vibrios, but it was not possible to make full bacteriological examination in every case. All the patients received the usual saline supportive treatment. The sulphadiazine series received powdered sulphadiazine 1 gramme, 4-hourly during the acute stage of the disease and three times a day for two days afterwards unless the patient left the hospital earlier.

TABLE I

Results of treatment of cholera cases with sulphadiazine as compared with a parallel series not receiving sulphadiazine. The general supportive treatment was the same in both series

	Treated with sulphadiazine	Not treated with sulphadiazine
Number in series ..	425	423
Number recovered	390	383
Number died ..	35 or 8.2%	40 or 9.5%

Further trials were undertaken using two parallel series, one receiving sulphaguanidine and the other sulphadiazine. The sulphaguanidine-treated series received powdered

* Sulphadiazine used for these trials was kindly donated by Messrs. May and Baker, Ltd. and Lederle Laboratories.

sulphaguanidine 3 grammes, 4-hourly during the acute stage of the disease and three times a day for two days afterwards unless the patient left the hospital earlier.

TABLE II

Results of treatment of cholera cases with sulphadiazine as compared with a parallel series treated with sulphaguanidine. The general supportive treatment was the same in both series

	Treated with sulphadiazine	Treated with sulphaguanidine
Number in series ..	451	463
Number recovered	415	443
Number died ..	36 or 7.9%	20 or 4.3%
	$\chi^2 = 5.4$; $P = 0.02$	

From the above results it will be seen that sulphadiazine has no appreciable effect on the mortality of cholera. A careful watch was maintained for the development of any toxic symptoms after the administration of sulphadiazine, but no ill-effects were observed. Sulphaguanidine on the other hand is of value in the treatment of cholera.

Summary

A series of 425 cholera patients were treated with sulphadiazine in addition to the usual saline supportive treatment. The death rate in this series was 8.2 per cent. A parallel series of 423 control cases not treated with sulphadiazine gave a death rate of 9.5 per cent.

Another series of 451 cases treated with sulphadiazine was compared with a parallel series of 463 cases treated with sulphaguanidine. The mortality in the sulphadiazine series was 7.9 per cent whereas in the sulphaguanidine series it was 4.3 per cent.

Sulphadiazine in the dosage used had no beneficial effect on cholera.

SULPHAGUANIDINE IN THE TREATMENT OF CHOLERA

By C. L. PASRICHA

LIEUTENANT-COLONEL, I.M.S.

Director, School of Tropical Medicine

B. M. PAUL

A. C. DAS GUPTA

and

A. K. DAS

(From the Cholera Treatment Unit, Indian Research Fund Association, School of Tropical Medicine, Calcutta)

SULPHAGUANIDINE has been reported on favourably in the treatment of cholera. The

published reports of the use of this drug in cholera are summarized in the January numbers of the Tropical Diseases Bulletin of 1943, 1945, 1946 and 1947. The number of cholera cases in which sulphaguanidine was tried and the results obtained are summarized in table I.

Although records were maintained of the age, sex, history and the clinical condition of each case the only criterion of the result of treatment used in this paper is the recovery or death of the patient. Whether the patient was admitted dying or died within a few hours or whether

TABLE I

The results of the treatment of cholera with sulphaguanidine as reported by different workers

Author	Year	Place of investigation	TREATED WITH SULPHAGUANIDINE		CONTROL SERIES	
			Number	Deaths	Number	Deaths
Chopra, R. N., deMonte, A. J. H., Gupta, S. K., and Chatterji, B. C.	1941	Calcutta (India)	281	7 or 2.2%	94	6 or 6.4%
Carruthers, L. B.	1942	Miraj (India)	50	7 or 14.0%	88	15 or 17.0%
Huang, J.	1944	Kweilin (China)	22	1 or 4.5%	Average cholera death rate in other hospitals 26%.	
Misra, K. N.	1944	Puri (India)	16	1 or 6.3%	70	22 or 31.4%
Lahiri, S. C.	1945	Calcutta (India)	114	17 or 14.9%	176	52 or 29.5%
Gupta, S. K., Chatterji, B. C., Paul, B. M., and Ghose, R. N.	1945	Calcutta (India)	263	3 or 1.1%	262	13 or 4.9%
Chu, L. W., Huang, C. H., Chang, C. T., and Kao, H. C.	1946	Chungking (China)	25	1 or 4.0%	29	1 or 3.4%
The hospital series in this paper	1947	Calcutta (India)	1,118	41 or 3.7%	1,170	88 or 7.5%
The village series in this paper	1947	Bengal (India)	60	11 or 18.3%	69	24 or 40.7%

There is reduction in the mortality in the sulphaguanidine-treated series and all workers except Carruthers (1942) claim that sulphaguanidine is of value in the treatment of cholera. The workers, who were able to treat only small series of cases, have based their claims for the efficiency of sulphaguanidine on clinical observations, such as the reduction of the duration of diarrhoea and vomiting, reduction in the amount of intravenous saline required and that anuria and other complications were less frequent in the sulphaguanidine series than in the control series of cases.

The present report is based on trial of sulphaguanidine* in a large series of cholera patients treated in a hospital in Calcutta and in a small series treated in villages under village home conditions. The selection of cases for treatment with sulphaguanidine was on alternate admission basis. All patients were suffering clinically from cholera presenting classical signs and symptoms. In many, the diagnosis was confirmed by the isolation of agglutinable vibrios but it was not possible to make full bacteriological examination in each case. In the hospital treated cases the usual saline supportive treatment was given as indicated. The sulphaguanidine-treated series received powdered sulphaguanidine 3 grammes, 4-hourly during the acute stage of the disease and three times a day for two days afterwards unless the patient left the hospital earlier.

death occurred from other causes than cholera has not been taken into consideration. All cases are taken as cholera and all deaths as due to cholera. In this way we have eliminated all factors which may introduce any bias in selection. The results of this trial are presented in table II.

TABLE II

Results of treatment of cholera cases in hospital with sulphaguanidine as compared with a parallel series not receiving sulphaguanidine. The general supportive treatment was the same in both series

	Treated with sulphaguanidine	Not treated with sulphaguanidine
Number in series	1,118	1,170
Number recovered	1,077	1,082
Number died ..	41 or 3.7%	88 or 7.5%
$\chi^2 = 15; P = 0.001$		

The inclusion of 52 more cases in the series not treated with sulphaguanidine was due to clerical error.

Cholera patients treated with sulphaguanidine under village conditions.—Hospital facilities were not available and effective supportive saline or other treatment was not possible. The patients were nursed by their relatives in their homes. The dosage of sulphaguanidine was the same as given to the patients treated in hospital. Those not receiving sulphaguanidine were given an

* Part of the sulphaguanidine used in this trial was kindly donated by Messrs. May and Baker, Ltd.

inert powder, calcium carbonate as a placebo, in the same dosage as the sulphaguanidine-treated cases. The results are given in table III.

TABLE III

Results of treatment of cholera cases with sulphaguanidine under village conditions as compared with those not receiving sulphaguanidine. No effective supportive treatment was possible

	Treated with sulphaguanidine	Not treated with sulphaguanidine
Number treated	60	59
Number recovered	49	35
Number died ..	11 or 18.3%	24 or 40.7%
	$\chi^2 = 7.16$; $P = \text{less than } 0.01$	

The results recorded above show that sulphaguanidine is of definite value in the treatment of cholera. Careful watch was kept for any toxic symptoms developing after sulphaguanidine therapy but with the dosage employed no toxic symptoms ascribable to sulphaguanidine were noted.

Summary

A series of 1,118 hospitalized cholera patients were treated with sulphaguanidine with a death rate of 3.7 per cent. A parallel series of 1,170 control cases were treated in exactly the same way but not given sulphaguanidine and the death rate was 7.5 per cent. A series of 60 cholera patients were treated with sulphaguanidine in village homes. No supportive treatment was possible. The death rate in this series was 18.3 per cent, whereas in a parallel control series of 59 cases, the death rate was 40.7 per cent.

Sulphaguanidine is thus of considerable value in the treatment of cholera.

A COMPARISON OF THE SUBCUTANEOUS AND INTRADERMAL METHODS OF IMMUNIZATION WITH T.A.B. VACCINE—AN EXPERIMENTAL STUDY

By M. NARAYANA PAI, M.B., B.S.
DINKER BABU RAO, M.B., B.S.

and

Miss B. KOMALAVALLI, M.B., B.S.

(From the King Institute of Preventive Medicine, Guindy, Madras)

ACTIVE immunization against typhoid and paratyphoid group of fevers is done by the time-honoured subcutaneous method of inoculation with T.A.B. vaccine. Tuft (1931) advocated the intracutaneous method of immunization by 4 doses of triple typhoid vaccine in doses of 0.05, 0.1, 0.15 and 0.2 c.c. with an interval of 5 to 7 days between one injection and the next. His conclusions were based on the agglutinin titrations of the individuals. Later he (Tuft, 1940) reported the results of mouse protection tests with pooled sera from 9 individuals who were inoculated intracutaneously with 3 doses of typhoid vaccine (0.1, 0.15 and 0.2 c.c.) at weekly intervals. A number of other workers have published papers on the subject, viz, Valentine *et al.* (1935), Perry (1937), Wyandt *et al.* (1938) and Van Gelder and Fisher (1941).

The intradermal or intracutaneous method of inoculation, though not preferred for the initial immunization, is recommended for 're-vaccination' (Luippold, 1944). Fennel (1942) however mentions the widespread practice of intracutaneous inoculation of the civilian population of Hawaii by the local health authorities.

Among the advantages claimed for the intracutaneous method is the fact that only about one-fifth of the amount of vaccine is required, i.e. whereas by the subcutaneous method (0.5 c.c. and 1 c.c.), 1.5 c.c. of vaccine is necessary for an adult, the same amount of vaccine is enough for five adults by the intracutaneous method in which 0.1 c.c. is given as the first dose and 0.2 c.c. as the second dose after a week. If this is accepted, it is obviously very economical. Another advantage claimed for the intradermal method is that reactions, either local or general, are very much less, owing to the smaller amount of antigen used. In fact, Perry (1937) states that he noticed no reactions with the intracutaneous method, whereas by the subcutaneous method there were a few reactions.

An experimental investigation was undertaken in the King Institute to evaluate the intracutaneous method of T.A.B. inoculation. Fifty-four rabbits (mostly males, with an average weight of 1,250 grammes), five human volunteers and ninety-two white mice, each weighing 16 to 18 grammes and about 4 weeks old, were used in the investigation.

Owing to lack of sufficient quantities of a reliable brand of mucin, and suitable mice, the mouse protection tests were very few, but the experiments are being continued and a further report will be made in a later paper.

Immunization

One batch of twenty-seven rabbits and three human volunteers was immunized by the subcutaneous method. The rabbits were given 0.2 c.c. and 0.4 c.c. of T.A.B. vaccine with an interval of one week between the injections. The human volunteers were given the usual 0.5 c.c. and 1 c.c. with an interval of one week between the injections.

Another batch of twenty-seven rabbits and two human volunteers was immunized by the

human volunteers was one week. No untoward reactions were noted after the intradermal inoculations either in rabbits or human volunteers.

One week after the second injection, samples of blood from the fifty-two rabbits which survived and the human volunteers were withdrawn, serum separated and used for estimation of 'H' and 'O' agglutinins (Widal test). A part of the serum from each case was stored in the refrigerator for about 2 to 3 weeks and then used for 'protection tests' on mice.

The results of the 'H' and 'O' agglutinin titres in rabbits before immunization and one week after the second immunizing dose are given in table I. The corresponding results in human volunteers are given in table II.

intradermal method. The rabbits were given 0.1 c.c. and 0.2 c.c. of T.A.B. vaccine* intradermally into the shaved skin of the abdomen. The human volunteers were given 0.1 and 0.2 c.c. intradermally into the skin of the upper arm. The interval between the first and second injections in the case of the rabbits as well as the

*The T.A.B. vaccine was prepared at the King Institute. It contained 1,000 million *Bact. typhosum* and 500 million each of *Bact. paratyphosum* A and B per c.c.

The results show that none of the rabbits and human volunteers showed any agglutinins 'H' or 'O' in their blood before the inoculations. One week after the second injection (considering 'O' titre as the index of immunity) 20 out of the 25 rabbits which were alive one week after the second injection showed an 'O' agglutinin titre of 200 and above and out of these 12 were titres of 400. In the subcutaneous immunization group, twenty-three out of twenty-seven rabbits showed a titre of 200 and above and out of these 12 were titres of 400.

TABLE II
Human volunteers

Num- ber	INTRADERMAL METHOD OF IMMUNIZATION					Num- ber	SUBCUTANEOUS METHOD OF IMMUNIZATION				
	Name	Before inoculation		1 week after 2nd injection			Name	Before inoculation		1 week after 2nd injection	
		'H'	'O'	'H'	'O'			'H'	'O'	'H'	'O'
1	Bhaskaran	—	—	—	+100	2	Dr. D. B.	—	—	+25	+100
	Nair.					4	D. R.	—	—	+50	+200
3	Subramanian	—	—	+100	+200	5	Ahmed Basha	—	—	—	—

Note : — means negative 1 in 25; + 100 means positive 1 in 100.

Two rabbits in the 'intradermal group' died probably as a result of intercurrent disease. The death was not due to the intradermal inoculation. None of the other rabbits which received the intradermal injections showed evidence of illness or severe reactions.

It is seen from the results that there is no appreciable difference between the 'O' agglutinin titres (or 'H' agglutinin titres) in the two groups.

Mouse protection tests

These tests were done according to the method described by Siler *et al.* (1941).

Technique.—White mice approximately 4 weeks old and 16 to 18 grammes in weight each were used. The minimum lethal dose (M.L.D.) of various strains of typhoid bacilli collected in the King Institute was determined as follows :—

As emulsion, in freshly prepared buffered Ringer's solution, of a 24 hours' smooth culture of *Bact. typhosum* was employed. Various doses of typhoid bacilli, i.e. 1,000, 2,000, 5,000, 10,000, 20,000, and 50,000 organisms were suspended in 0.5 c.c. of 5 per cent mucin and used for injection of mice.

(The solution of mucin was prepared a week earlier according to the method described by Siler *et al.* 1941, and stored in the refrigerator, so that, a uniform suspension was obtained.)

The mucin suspension of living typhoid bacilli was used to eliminate as far as practicable the reactions attributable to direct toxicity that would follow the administration of large numbers of typhoid bacilli.* By using a number of strains, one was selected, which gave the most uniform results.

A dose of 5,000 organisms of this strain ('Arogyaswami') suspended in 0.5 c.c. of 5 per cent mucin was found to be the minimum lethal dose for mice weighing 16 to 18 grammes in the

sense that all the four mice inoculated intraperitoneally with this dose died within 72 hours.

Having selected the strain of *Bact. typhosum* and estimated the M.L.D. of this strain, we proceeded as follows :—

Groups of 4 mice or 3 mice (depending upon the number of mice available) were used for each experiment. The mice were injected intraperitoneally with 0.1 c.c. of the immune serum from the rabbit or human volunteers as the case may be ('subcutaneous group' or 'intradermal group'). Half an hour later, a 'challenging dose' of 100 M.L.D., 1,000 M.L.D. and 10,000 M.L.D. in mucin solution of the standard strain selected was injected intraperitoneally. The immune serum was obtained from the rabbits and human volunteers mentioned in tables I and II and stored for at least 2 weeks in the refrigerator to eliminate the interfering action of complement. The mortality of the mice within 72 hours was noted and the results are appended in table III (*vide infra*).

The number of mouse protection experiments is small owing to limited facilities. More such experiments are necessary to give a definite opinion. The results mentioned however show that the serum from intradermally injected rabbits and human volunteers showed approximately the same protective value as the serum from subcutaneously injected rabbits and human volunteers. Further work is in progress.

Summary

1. Twenty-seven rabbits and three human volunteers were immunized with T.A.B. vaccine by the usual subcutaneous method.

2. Twenty-seven other rabbits and two other human volunteers were immunized by the intradermal method.

3. The 'H' and 'O' agglutinin titres of all the rabbits and human volunteers were negative 1 in 25 before the injections.

4. The 'H' and 'O' titres of the group receiving the vaccine by the intradermal route were approximately the same as the titres of the 'subcutaneous' group.

* Mucin really enhances the virulence of the organism according to Topley and Wilson's 'Principles of Bacteriology and Immunity', 1946.—EDITOR, I.M.G.

TABLE III
Mouse protection tests

IMMUNE SERUM FROM INTRADERMAL INJECTIONS			IMMUNE SERUM FROM SUBCUTANEOUS INJECTIONS		
Serum from	Challenging dose of <i>B. typhosus</i>	Mortality in mice in 72 hours	Serum from	Challenging dose of <i>B. typhosus</i>	Mortality in mice in 72 hours
B. Nair (human volunteer).	100 M.L.D. 1,000 M.L.D.	3/4 2/4	Subramania Iyer (human volunteer).	100 M.L.D. 1,000 M.L.D.	0/4 2/4
Rabbit no. 1 ..	100 M.L.D. 1,000 M.L.D. 10,000 M.L.D.	3/4 3/4 3/4	Rabbit no. 2 ..	100 M.L.D. 1,000 M.L.D. 10,000 M.L.D.	3/3 3/3 3/3
Subramanian (human volunteer).	100 M.L.D. 1,000 M.L.D.	1/3 2/4	Madhava Rao (human volunteer).	100 M.L.D. 1,000 M.L.D. 10,000 M.L.D.	0/4 3/4 2/4
Rabbit no. 12 ..	100 M.L.D. 1,000 M.L.D. 10,000 M.L.D.	2/4 1/4 1/4	Rabbit no. 9 ..	100 M.L.D. 1,000 M.L.D. 10,000 M.L.D.	1/4 1/4 2/4
			D. Rao (human volunteer).	100 M.L.D. 1,000 M.L.D. 10,000 M.L.D.	4/4 3/4 4/4

In the mortality column, the bottom figure is the number of mice employed in the experiment and the top figure is the number of mice which died in 72 hours. Thus 3/4 means that 3 mice died in 72 hours out of 4, i.e. one survived.

5. Mouse protection tests were done with immune serum from two rabbits and two human volunteers immunized by the intradermal method. Similar tests were done with immune serum from two rabbits and three human volunteers immunized by the subcutaneous method. The protective value in mice in both groups was approximately the same.

Acknowledgment

Our thanks are due to Mr. V. R. Srinivasan for assistance in preparing solutions of mucin and buffered Ringer's solution.

ROENTGEN THERAPY IN TUBERCULOUS CERVICAL LYMPHADENITIS

By M. AHMAD HASSAN SIDDIQUE, M.B., B.S.
Dow Medical College, Karachi

RADICAL operation of glands in the neck leaves very bad scars, and moreover it is practically impossible to remove all the infected glands. Recurrence rate after radical operation is also high.

Moreover, the cosmetic results of surgical excision are not significantly better than those of untreated cases. Good cosmetic result is really the first aim of treatment. Thompson (1936, 1937) collected 2 series of cases, 43 and 35 respectively, in which tuberculous cervical glands liquefied and broke down spontaneously owing to the neglect and refusal of the treatment in the earlier stages and compared the cosmetic results with those of surgical excision.

1st series of 43 cases

Cosmetic results	Good	Moderate	Bad
Surgical excision (43 cases).	21% (9 cases)	30% (13 cases)	49% (21 cases)
Spontaneous ulceration (43 cases).	30% (13 cases)	35% (15 cases)	35% (15 cases)

2nd series of 35 cases

	Surgical excision	Spontaneous ulceration
Good ..	8	8
Moderate ..	15	12
Bad ..	12	15

It is clear from these figures that the results of what may be termed natural cure though occurring under the worst possible hygienic conditions are far from being calamitous and indeed actually superior to expert surgery. But this does not mean that such cases should go untreated.

Orley (1936) got excellent cosmetic results from small repeated doses of x-rays. Howarth (1924) got good results with x-rays when sinuses existed. Smith (1922) obtained good results with sun light. Mosdzein considers a combined x-ray and sun-ray treatment as most favourable.

I have treated nearly 200 cases of T.B. glands in the neck by x-ray therapy. The cases were diagnosed as tuberculous: (1) On clinical grounds; on long standing history of sinuses, etc. (2) On blood examination: (a) total and differential count, (b) E.S.R. (1st hour Westergren method). (3) By tuberculin test. (4) By other examinations: (a) skiagram or screening of the chest, (b) search for a septic focus in the drainage area of the lymph glands of the neck, i.e. scalp, ears, nose, throat and teeth. In doubtful cases the diagnosis was confirmed by (a) examination of aspirated or curetted material and (b) biopsy.

Early cases were treated by superficial x-rays (K.V. 85, filter 3 mm. Al., milliamperage 5, time 4½ minutes, distance 20 cm., size of the field sufficient to include the area between the middle line in front, anterior border of the trapezius behind, upper border of the clavicle below and a line drawn at the level of the zygomatic arch above, number of the Roentgen units was 150 per exposure) and advanced cases were treated by deep x-ray (K.V. 300, filter 1 mm. Al., ½ mm. cμ, milliamperage 4, time 10 minutes, distance 50 cm., size of the field 15 × 15 cm., Roentgen units 150 per exposure). One exposure was given per week for unilateral cases and 2 for bilateral cases for 6 weeks. This was termed as one course (total dosage for unilateral cases 900r and for bilateral cases 1800r). This course was repeated after 6 to 8 weeks' interval. Most of the cases needed 2 or 3 courses. This treatment gave remarkably good results.

An account of 8 striking cases treated in this series by x-ray therapy follows with photographs, taken before and after treatment.

Case no. 1

P. K., age 15, Hindu female (unmarried). Date of coming under observation 21st May, 1945.

Complaints: (1) Enlargement of the glands on the left side of the neck; duration 9 months. (2) Malarial fever; duration 1 month.

Mother died of tuberculosis of the lungs and one of her brothers was suffering from tuberculosis of the hip joint.

She got enlargement of the glands on the left side about 2½ years ago. She got herself operated upon at Sir Ganga Ram Hospital, Lahore, about two years back. The glands recurred six months after the operation as two or three small nodules and she came to the Mayo Hospital, Lahore, for Roentgen therapy.

The patient was otherwise quite healthy, weight 80 pounds. Local examination showed a swelling below and behind the angle of the jaw 3 inches × 4 inches under a scar 4 inches × ½ inch of the previous operation on the left side of the neck. This mass of glands was matted. Blood examination: (a) Total W.B.Cs. 8,000, polymorphs 55 per cent, lymphocytes 40 per cent, large mononuclears 5 per cent, eosinophiles nil, (b) E.S.R. 28 (1st hr. Westergren). Screening of the chest negative. Tuberculin test 1:10,000 (+++).

She was given two courses of superficial x-ray therapy at an interval of 2 months. After the end of the first course the glandular swelling was examined and it measured 2 inches × 1 inch. At this time her weight was 100 pounds and her E.S.R. was 9 mm. (1st hr. Westergren method). At the end of the second course the glands were no longer palpable and her E.S.R. remained normal (8 mm.). The fever which she had to start with subsided after 2 days of quinine administration (figures 1 and 2; plate XVIII).

Case no. 2

S. K., age 14, Sikh female (unmarried). Date of coming under observation 15th July, 1945.

Complaints: (1) A swelling on the right side of the neck; duration 1 year. (2) A swelling in the left axilla; duration 1½ years.

The swelling in the axilla was first to appear and it was followed two months afterwards by the enlargement of the glands in the neck. She carried out conservative treatment since the first appearance of the enlargements with no relief and she left her studies on account of her illness. She was fairly built and was otherwise quite healthy.

Weight 80 pounds. Local examination showed a mass 4 inches × 5 inches under the upper part of the right sternomastoid and an irregular swelling 4 inches × 3 inches in the right posterior triangle. The glands were matted together. The axillary mass measured 5½ inches × 4 inches. Blood examination: (a) Total W.B.Cs. 8,125; polymorphs 65 per cent, lymphocytes 30 per cent, large mononuclears 3 per cent, eosinophiles 2 per cent. (b) E.S.R. 19 mm. Skiagram of the chest negative. Tuberculin test 1:10,000 (+++). Some of the glands were removed

from the axilla and were sent to the pathology department for examination and they turned out to be tuberculous. She was given two courses of superficial x-ray therapy. At the end of the first course the axillary swelling was reduced to 2 inches \times 1 inch and the swelling in the neck was hardly palpable (1 inch \times 1 inch and $1\frac{1}{2}$ inches \times $\frac{3}{4}$ inch). She gained 20 pounds in weight and joined the school. She was again put on superficial x-ray therapy after $1\frac{1}{2}$ months and was discharged cured on 20th November, 1945. Her E.S.R. was 8 mm. at the end of the first course and never rose up again except once during the second course when it became 19 mm. She had then a temperature. The E.S.R. again came to 8 mm. after the end of a week (figures 3 and 4, plate XVIII).

Case no. 3

V. V., age 25, Hindu female (married). Date of coming under observation 25th August, 1945.

Complaints: (1) Enlargement of the lymph glands on both sides of the neck, duration 2 years. (2) Slight fever, duration $1\frac{1}{2}$ months. (3) Cough, duration one month. (4) Frequent attacks of bad cold, duration 6 months. (5) Loss of appetite, general weakness and indisposition to work, duration 6 months.

About 2 years back she noticed a swelling on the right side of the neck just below and behind of the angle of the mandible. This swelling went on increasing in spite of all sorts of treatment carried out by her till the glands in other parts of the neck also became palpable. She was quite intelligent and fairly well built. Weight 95 pounds. Local examination showed: I Right side—(1) A swelling 4 inches \times 5 inches just below and behind the angle of the mandible. (2) A swelling 4 inches \times 3 inches deep to the lower half of the sternomastoid. (3) A swelling 1 inch \times 1 inch behind the pinna. (4) A mass of gland 3 inches \times $3\frac{1}{2}$ inches in the supra-clavicular region just behind the posterior border of the sternomastoid muscle. All the swellings contained matted glands. II Left side—The glands formed slight nodular swellings scattered all over and were just palpable. Blood examination: Total W.B.Cs. 8,125, polymorphs 70 per cent, lymphocytes 25 per cent, large mononuclears 4 per cent and eosinophiles 1 per cent. E.S.R. 19 mm. Malarial parasites present. Skiagram of the chest negative, tuberculin test 1:10,000 (+). On biopsy the diagnosis of tuberculous lymphadenitis was confirmed. She was given two courses of deep x-rays. Her fever and bad cold disappeared after the use of the ordinary medicines. Her weight began to improve after 4 weeks. At the end of the first course she gained 10 pounds in weight and her E.S.R. became 7 mm. (1st hr. Westergren). At the end of the first course the glandular swellings were hardly palpable except that portion under the upper part of the sternomastoid

just below and behind the angle of the jaw (2 inches \times 1 inch). After the second course all the glands returned to their normal size and she improved in general health (figures 5 and 6, plate XVIII).

Case no. 4

K. B., age 30. Date of coming under observation 15th August, 1945.

Complaint: Recurrence of the glandular enlargements after a radical operation performed on right side, at Bombay, about one year back.

She was slightly pale and anæmic, weight 85 pounds. Local examination showed a mass of matted glands 3 inches \times 4 inches in the right jugular chain under a big scar of the previous operation. There was an abscess associated with a swelling 1 inch \times 2 inches in the right posterior triangle. There were scattered nodular enlargements of all the glands on both sides of the neck. Blood examination: Total W.B.Cs. 5,400, polymorphs 56 per cent, lymphocytes 40 per cent, large mononuclears 3 per cent, eosinophiles 2 per cent, total R.B.Cs. 4 millions, Hb 70 per cent, E.S.R. 22 mm. (1st hr. Westergren). Skiagram of the chest negative, tuberculin test 1:10,000 (+). On biopsy the diagnosis of tuberculous glands was confirmed. The abscess healed after three aspirations. After one course of deep x-rays, her weight increased to 100 pounds. Her E.S.R. became 8 mm. after 4 weeks. She was put on an ordinary iron mixture and her anæmia improved. The progress was uneventful and she improved in her general health. On examination on 1st November, 1945, the glandular masses had completely disappeared and the scar of the previous operation became just visible (figures 7 and 8, plate XVIII).

Case no. 5

S. D., age 25, Hindu female (married). Date of coming under observation 5th September, 1945.

Complaint: Enlargement of the glands on both sides of the neck, marked on the right side; duration 2 years.

She was fairly well built and was otherwise quite healthy, weight 100 pounds. Local examination showed: (1) A swelling 4 inches \times 5 inches just below and behind the angle of the right mandible. (2) A swelling 3 inches \times 4 inches under the lower part of the right sternomastoid muscle. (3) Small nodular swellings scattered on both sides of the neck. The swelling nos. (1) and (2) contained matted glands. Blood examination: (a) Total W.B.Cs. 5,625, polymorphs 66 per cent, lymphocytes 30 per cent, large mononuclears 1 per cent, eosinophiles 3 per cent. (b) E.S.R. 10 mm. (1st hr. Westergren). Screening of the chest negative. Tuberculin test 1:10,000 (+++). On biopsy the diagnosis of tuberculous glands was confirmed. She was given one course of superficial x-ray therapy. At the end of the treatment her

weight was 110 pounds, E.S.R. 10 mm. (1st hr. Westergren). She was discharged cured on 1st November, 1945, because all the glands returned to their normal size (figures 9 and 10, plate XIX).

Case no. 6

S., age 25, Mohammedan female (unmarried). Date of coming under observation 10th September, 1945.

Complaints: (1) Enlargement of the lymphatic glands on the right side of the neck; duration 9 months. Since one month some of the glands had softened and burst. There was a sinus giving a serous discharge. (2) Slight cough and occasional fever; duration 6 months.

She was pale and anæmic, weight 90 pounds. Local examination showed a swelling of glands 5 inches \times 4 inches under the right sternomastoid and extending into the posterior triangle. A fluctuant mass was also palpable in the upper part of the jugular chain. There was an ulcer 1 inch \times $\frac{3}{4}$ inch over the swelling, discharging pus. The blood examination: (a) Total W.B.Cs. 5,760, polymorphs 64 per cent, lymphocytes 31 per cent, large mononuclears 4 per cent, eosinophiles 1 per cent. (b) E.S.R. 11 mm. (1st hr. Westergren). Skiagram of the chest negative. Tuberculin test (+++). Examination of the aspirated material from the abscess showed no micro-organisms. She was given one course of deep x-ray therapy during which the abscess was regularly aspirated. At the end of 3 weeks her E.S.R. became 10 mm. (1st hr. Westergren) and she gained 10 pounds in weight. At the end of the treatment the glands returned to the normal size, the abscess subsided and she was allowed to go on 16th November, 1945, as cured (figures 11 and 12, plate XIX).

Case no. 7

P. C., age 7, Hindu, male child. Date of coming under observation 1st October, 1945.

Complaint: A swelling on the left side of the neck; duration one year. Child was quite healthy, weight 50 pounds. Local examination showed a swelling 3½ inches \times 3 inches consisting of large discrete gland just below and behind the left jaw and small nodular swellings just palpable in other areas on the left side of the neck; skiagram of the chest negative. Blood examination: Total W.B.Cs. 6,000, polymorphs 55 per cent, lymphocytes 40 per cent, large mononuclears nil, eosinophiles 5 per cent. E.S.R. 28 mm. (1st hr. Westergren). Stool examination: Ova of oxyuris found. Tuberculin test 1:10,000 (+++). In the beginning he was treated for oxyuris. Then he was given one course of superficial x-ray therapy. At the end of the treatment the glandular masses completely disappeared and E.S.R. came to 10 mm. (1st hr. Westergren) and he was discharged cured on 20th December, 1945 (figures 13 and 14, plate XIX).

Case no. 8

M. A., age 16, Mohammedan male (unmarried). Date of coming under observation 1st November, 1945.

Complaint: Extensive enlargement of the glands on both sides of the neck with a big scar and discharging sinuses on the right side; duration 2 years.

The patient was slender built, weight 100 pounds. Local examination showed: I Right side—(1) Just behind and below the angle of the jaw a swelling 3 inches \times 3 inches. (2) A scar 4 inches \times $\frac{1}{2}$ inch extending from behind the angle of the jaw to just above the sternum. (3) Two swellings each 1 inch \times 1 inch along the posterior border of the sternomastoid about its middle. (4) A swelling 3 inches \times 2 inches in the paratoid region. (5) There were two sinuses in the glands of the upper chain and one in the middle. The glands in the swelling no. 1 were matted together but others were quite discrete. II Left side—(1) A swelling 4 inches \times 4 inches just behind the angle of the jaw. (2) A swelling 4 inches \times 3 inches in the supraclavicular region. (3) A swelling 3 inches \times 2 inches along the posterior border of sternomastoid. The glands in all the swellings were quite discrete.

Blood examination: (a) Total W.B.Cs. 5,750, polymorphs 64 per cent, lymphocytes 31 per cent, large mononuclears 4 per cent, eosinophiles 1 per cent. (b) E.S.R. 12 mm. (1st hr. Westergren). Skiagram of the chest negative. Tuberculin test 1:10,000 (+). Biopsy of the glands confirmed the diagnosis of tuberculous glands. The sinuses were curetted and bipped. Glands on the right side belonging to the group no. 1 were removed for biopsy. He was given one course of x-ray therapy and at the end of the treatment the glands diminished markedly on the right side, the scar became insignificant and sinuses healed, but there was only slight decrease on the left side. His E.S.R. became normal, 8 mm. (1st hr. Westergren). He never turned up again for another course of treatment (figures 15 and 16, plate XIX).

Comments

X-ray treatment gives an excellent result in a month or two and strains the purse of a poor class of tuberculous community to the minimum, eradicated the disease, whether residing in the superficial or deep glands, or in between the various groups. Further, the aftermaths of conservative treatment, namely, the further dissemination of the disease, extensive adhesions to various important structures of the neck leading on to the stage of inoperability and period of treatment stretched over many years, are all eminently avoided. Roentgen therapy also surpasses the operative radical method in that that bad scar, fear of mortality and recurrence due to the liability of any focus left behind are all properly dealt with. However, I must admit that operative method has got to

be resorted to in cases who are refractory to x-ray therapy.

Summary

I have reported 8 cases of T.B. glands in the neck. Excellent results were obtained in all cases except one who did not turn up for further treatment. A short comment on the treatment is presented.

A MODIFIED BONE GRAFT FOR ARTHRODESIS WRIST

By I. R. BAZLIEL

MAJOR, I.M.S./I.A.M.C.

Surgical Specialist, Orthopaedic Wing, I.M.H., Lucknow, U. P., India

DURING 1944-46 over a dozen cases of traumatic osteo-arthritis of wrist, either due to gunshot wounds or simple fractures involving the articular surfaces, had to be treated in this centre surgically. In every case prolonged physiotherapy and rehabilitation exercises had been instituted before deciding upon surgical interference to estimate the functional disability. Persistent pain and tenderness had been a guiding factor in every case tackled surgically.

Having employed 'Britain's' technique for arthrodesis of the wrist in the first few cases, the difficulty of giving an adequate amount of dorsiflexion to the wrist was invariably experienced. A forced dorsiflexion usually lifted the graft out of the central portion of the bed. Consequently, I have ventured to modify the usual Britain's graft by cutting it angular instead of straight (see figure 1), and have used it in eight cases with remarkable success.

Figure 1.

No extra difficulty is experienced in cutting this graft out of the tibia with Albee's saw. The operation technique is the same as described by Britain. After the gutter has been made in the radius and the carpus, the wrist is held by an assistant in the required dorsiflexion position and accurate measurement of the gutter on either side of the wrist joint is taken. The angled graft is marked on the tibia with the usual steps at its ends. When the graft is precisely fitted in the

gutter with the convex angle down in the wrist joint, the wrist is automatically kept in dorsiflexion.

Another advantage is that in optimum dorsiflexion of the wrist the grip is much stronger and functional result far better than when the wrist is arthrodesed in a neutral position.

The accompanying x-ray pictures (see figures 2, 3 and 4, plate XX) show an arthrodesis performed for flail wrist, with angular graft, taken 3 months after the operation.

GANGOSA

By K. D. LAHIRI, M.B., B.S.

Senior Honorary Medical Officer, Skin and V. D. Department, Patna Medical College Hospital, Bihar

GANGOSA is a Spanish word meaning muffled voice. The Spanish Commission in 1928 separated gangosa from leprosy. It is associated with yaws usually but in the case under report yaws could not be proved. Authorities have found it impossible to decide whether gangosa is due to syphilis or yaws. Histopathological studies have proved that gangosa has no relationship with leprosy and they do not suggest syphilitic origin but the lesions gave evidence of a chronic inflammatory condition in which there was a tendency to destruction of newly formed tissue with little tendency to invasion by micro-organisms. Hallenberger believes that rhinopharyngitis mutilans belongs to the syphilis-frambæsia group and thinks it as a late lesion of frambæsia.

Gangosa generally starts as a patch of membrane in the soft palate. This membrane rapidly becomes honeycombed and in 3 to 4 days a deep ulcer appears underneath the membrane. This ulcerating process extends from within outwards quickly destroying on its way soft parts giving a funnel-shaped appearance. The nasal duct is prone to be attacked and through this the disease spreads and produces mutilation of the face.

Case report.—Ganga Sao, Hindu male, 45 years old, married, has 3 living children, is an inhabitant of Bihar, and is a shopkeeper by profession. History of having had a sore penis following an extra-marital contact about 17 years back and had only two injections of N.A.B. for joint pain 10 years back.

He had no skin rash but 4 years back he noticed a rough area on his soft palate which went on increasing very rapidly until the whole of the soft palate and a part of the hard palate sloughed off and nasal twang appeared in about 7 months' time. He was under some homœopath at this time. Only 2 years back he noticed a small swelling like that of a big pea on the left side of his nose which in about 4 months' time became as big as the betel-nut and few weeks after softened at the top when a barber operated on him and put in a gauze. The wound healed up in 3 months' time leaving an opening on the cheek

and nose and in talking he has to cover that opening with his left hand. He came for treatment here in 1946.

The photograph (see figure 1, plate XXI) shows a funnel-shaped opening on his face leading into the rhinopharynx. Blood W.R. repeatedly has been positive even after routine anti-syphilitic therapy (Lahiri, 1945) which checked further destruction of the ulcer on the left lower leg (see figures 2 and 3, plate XXI). This ulcer had no special characteristics, looked more or less like Naga Sore and did not have the typical hunched out look of a gummata. The skiagrams of the skull (see figures 4 and 5, plate XXI) do not show much in support of the yaws in gangosa but the destruction of the maxilla and palate are seen. Penicillin was also tried (Lahiri, 1947) but not with much effect, and without altering the serological reaction of the patient.

I am thankful to the Superintendent for permission to publish this paper and to Dr. Nawab and Major Sinha for help.

STUDIES ON GASTRIC ANALYSIS WITH DIFFERENT TEST MEALS*

By R. N. CHAUDHURI, M.D., M.R.C.P., T.D.D., F.S.M.F.
Professor of Tropical Medicine

and

M. N. RAI CHAUDHURI, M.D.

Research Worker

(From the School of Tropical Medicine, Calcutta)

GASTRIC analysis is of value in the investigation not only of gastro-intestinal diseases but also of other conditions, viz anæmias, pellagra, asthma, etc. In this test, after the removal of the residual juice, the gastric glands are excited to secrete by the ingestion of a test meal of which oatmeal gruel is the old standard one. It has however certain disadvantages: it takes considerable time to prepare the meal; the patient finds it inconvenient to swallow with a tube in the mouth; a pint of gruel causes much dilution of the gastric juice at least in the first hour; and at times difficulty is experienced in drawing the thick samples through the tube. More recently, alcohol test meal has replaced the gruel meal. In this country, Napier, Chaudhuri and Rai Chaudhuri (1938) used the alcohol meal

in the study of gastric acidity in health and disease of Indians. Mangalik, Goel and Mangalik (1942) made a comparative study between the gastric response to alcohol and gruel meals showing that alcohol is an equally good or even better gastric stimulant. The meal consists of 100 c.c. of 7 per cent alcohol. It is easy to prepare and easy to pass directly into the stomach through the tube; the samples are clear and are withdrawn with ease while there is very much less dilution of the gastric juice. It is a gastric stimulant, although, of course, not a natural one at least in most Indian patients. Not infrequently, objections are raised by certain patients against alcohol being put in their stomach. The object of the present study was therefore to perform gastric analysis with various common articles of meal and compare the results with those of the alcohol meal.

This report deals with 200 gastric acid secretion studies, performed on 100 patients suffering from different diseases, who were admitted into the Carmichael Hospital for Tropical Diseases. The series was a mixed one as regards race, sex and age. It was divided into ten groups of ten patients each. Each of the first nine groups was given both types of meal—the alcohol meal first and then at an interval of a few days the meal to be tested, and the results were compared. In the tenth group the same alcohol meal was repeated the second time with a purpose to seeing if there were any variations from the first observations. The following is the list of different meals used:—

- (1) Tap water.
- (2) Distilled water.
- (3) Pyrogen-free water.
- (4) Normal saline.
- (5) Pepper water.*
- (6) Tea infusion.
- (7) Milk.
- (8) Olive oil.
- (9) 'Rasam'.†

Method of study

All the subjects were ambulatory. They were permitted a light supper the evening before and were given four charcoal tablets at 10 p.m. They were not allowed any food next morning until the test was done. The stomach was first emptied of the fasting contents and the meal (100 c.cm. each) was administered through Ryle's

* Pepper water is prepared by adding 0.5 gm. of powdered pepper to 100 c.cm. of distilled water and shaken well before giving the meal.

† Ripe tamarind pulp is soaked in water for half an hour. Adequate amount of 'masala' powder (a mixture of pepper, chilli, turmeric, dhania, chana dal powder, etc.) and salt added. This is then allowed to boil till the right flavour begins to emanate, when dal (arhar) water, previously cooked, is added. It is removed from fire. The preparation is now flavoured with fried mustard, etc. The supernatant fluid is 'rasam'.

* A paper presented at the 34th Session of the Indian Science Congress held at Delhi in 1947.

tube. Then quarter-hourly samples of gastric contents were withdrawn for two hours. Each fraction was titrated with 0.1 normal sodium hydroxide for free and total hydrochloric acid, Topfer's reagent (0.5 per cent solution of dimethyl amino-azo-benzol in alcohol) and phenolphthalein (1 per cent solution in alcohol) being used respectively as indicators.

Acidity standards

The cases were classified on the basis of their acid response, as shown below, in accordance with the grouping suggested by Napier, Chaudhuri and Rai Chaudhuri (1938) and routinely followed in this institution.

Acid response	Free HCl in c.cm. per 100 c.cm. gastric contents

Hyperchlorhydria .. Over 65

Normal range—

(a) High \therefore Over 45

(b) Medium .. 25 to 45

(c) Low .. Under 25

Hyperchlorhydria .. Under 10

Achlorhydria .. No free HCl

No reference to the total acidity is made as it runs more or less parallel with the free acidity.

Results

These are shown in tables I and II.

Table I shows the result with each meal as compared with alcohol. It will be noticed that both tap water and pyrogen-free water gave the same results as alcohol in 70 per cent of the cases. There were variations in the remaining 30 per cent, but these variations were of minor degree. Thus in one person who was 'high normal' with alcohol gave 'normal' reaction with tap water and in another person a 'normal' from alcohol became 'high normal' with pyrogen-free water. It may be said that 30 per cent is a large figure but it must be remembered that the number of cases in each group was small. It is interesting to note that the same minor variations were observed when alcohol was used as the second test meal.

In the case of other substances which were tested we found that the differences from alcohol were marked with tea infusion and *rasam* and intermediate with distilled water, pepper water, normal saline, milk and olive oil. Incidentally, compared with alcohol, tea, milk, olive oil and normal saline tended to depress the acidity, while *rasam* slightly increased the acidity in 70 per cent of the cases.

Table II represents the maximum and mean acid secretions in the different groups. The curves of mean acidity with tap water and pyrogen-free water (figures I and II) run closely

TABLE I

Group	Test meal	1	2	3	4	5	6	7	8	9	10

Curves of mean acidity with four different test meals as compared with alcohol.

Figure V shows results with the same alcohol meal repeated.

FIG I.

FIG IV.

FIG II.

FIG V.

FIG III.

parallel with that of alcohol. Olive oil gave similar results during the first hour but eventually controlled the secretion, and during the second hour there was some divergence (figure III). With *rasam* there was higher acidity throughout the period of observation (figure IV). With alcohol tested for the second time the mean results almost corresponded with those of the first observations (figure V).

As regards maximum acidity, tap water and pyrogen-free water were the only two substances which approached the high level obtained with alcohol, and the peak was reached within 1 1/2 hours.

Conclusion

Gastric analysis is not an exact procedure for it is dependent on a series of factors which change in a given individual from time to time but, if carefully carried out, it is a valuable aid to diagnosis. The composition of the meal is one of the variable factors, and the simpler it is the better. If we accept alcohol as the standard meal, then judging from the above results, it may be replaced by ordinary water. Its advantages are obvious. But our results need confirmation from a larger series of cases.

SOME CONSTITUENTS OF NORMAL BLOOD

A STUDY BASED ON THE EXAMINATION OF THE BLOOD OF 50 PERSONS, 25 MEN AND 25 WOMEN

By S. H. GOKHLE

and

R. J. LOKRE

Department of Pathology and Microbiology, King Edward Hospital Medical School, Indore, C. I.

QUANTITATIVE estimation of some constituents of blood has become a common practice in clinical medicine. In order to have a definite idea of the extent of the severity of the pathological condition, standard values for the constituents estimated in normal human blood are essential. The values usually found in the textbooks refer to the Westerners, worked out by the workers of the West (e.g. Folin, Wu, Van Slyke;

Brown, White Horn and many others). For the first time in India workers of the Haffkine Institute, Bombay, worked a few normals for Indians in general and Bombayites in particular (Sokhey and others, 1937, 1938). Subsequent work done at Calcutta, Madras and Bangalore produced some normals for the local or the provincial people of the respective places. So far no such figures were available for Central India and hence the undertaking of this work.

The students from the King Edward Hospital Medical School and nurses attached to the King Edward Hospital, were the subjects of our examination. These were young men and women, apparently healthy and varying between eighteen and twenty-eight years. These represented persons from the lower middle class and upper lower class. Majority of these are vegetarians, a few accustomed to eggs or meat now and then and a negligibly small number habituated to either meat or eggs daily.

The subjects under examination were allowed to have their usual diet at the night previous to their blood being drawn. On the morning of the examination day they were instructed to have if they chose only a cup of tea and three hours after this their blood was collected in specially prepared oxalated bulbs containing 2 mg. of neutral potassium oxalate per c.c. of blood as anticoagulant. It was also carefully investigated that the person concerned had not taken any sulphur or other drugs within last few months prior to his examination. Ten c.c. of venous blood were collected for the various examinations carried out, care being taken to use a dry sterilized syringe. All estimations were finished within two hours of the collection of the blood.

Blood from finger tips by a prick was collected in standard German pipettes for the cell counts and hæmoglobin estimation by Hellige's hæmometer.

SEROLOGICAL TECHNIQUE (contd.)

By S. D. S. GREVAL

LIEUTENANT-COLONEL, late I.M.S.

(From the Laboratory of the Imperial Serologist and Chemical Examiner to the Government of India, School of Tropical Medicine, Calcutta)

The Cerebrospinal Fluid

Charging of tubes for cerebrospinal fluid.—The fluid is not inactivated. Greater care, therefore, is necessary in its preservation than in the preservation of the serum.

Seven tubes in a row running from left to right, not in a column from front to backwards, are used and charged as follows:—

	FOR CONTROL			FOR ANTIGEN NO. 1 OR NO. 3		FOR ANTIGEN NO. 2	
	1st tube	2nd tube	3rd tube	4th tube	5th tube	6th tube	7th tube
CSF undiluted ..	2 vol.	1 vol.	2 vol.	1 vol.	2 vol.	1 vol.	2 vol.
1 vol. of antigen	No. 4	No. 4	No. 1 or No. 3.	No. 1 or No. 3.	No. 2	No. 2
1 vol. comp. dil. containing : Antigen and comp. dil. are mixed as before for serum.	2 MHD	2 MHD	2 MHD	3 MHD	3 MHD	4 MHD	4 MHD
Saline ..	1 vol.

The rest of the procedure is the same as for serum.

It will be observed that the 5 MHD tube, as used in the serum test, is not put up.

Reading of the results for cerebrospinal fluid.—This is done as in the case of the serum (i) immediately and (ii) after the tubes have been in the ice-box overnight. A poor \pm (poor deposit and no decrease in the colour of the supernatant fluid) and a ?—, of course, are not significant.

Record and report for cerebrospinal fluid.—One difference between the reaction of the serum and that of the CSF is observed: *Anticomplementary titre of the control is low or nil.* One difference between the report on the serum and that on the CSF is made: *Inhibition of hæmolysis in the tubes containing 2 volumes of undiluted CSF, even when complete, is not accepted as a positive reaction unless there is also a definite inhibition of hæmolysis (frankly*

\pm at least) in the tube containing 1 volume of the fluid.

Due to these differences the significant combinations are not as many as those in the test for serum. The results are recorded and reported as follows:—

- +++, positive, strongly .. When complete inhibition of hæmolysis occurs with antigen no. 2 in one or both tubes, subject to the provision concerning 1 volume.
- ..
- ++, positive .. When complete inhibition of hæmolysis occurs with antigen no. 1 or no. 3 in both tubes.
- +, positive, weakly .. When the inhibition is complete with antigen no. 1 or no. 3 with 2 volumes of CSF and partial but well marked with 1 volume.
- \pm , doubtful .. When partial but well-marked inhibition occurs in one or both tubes with antigen no. 1 or no. 3.
- , negative .. When no inhibition or inhibition of poor quantity occurs with antigen no. 1 or no. 3.

A strong inhibition with antigen no. 4 lends support to a weaker inhibition with antigens nos.

1 and 3, which might otherwise be considered not well marked or of poor quality.

Anomalous Reactions

Anomalous reactions such as more fixation with 5 MHD than with 3 MHD do not appear to occur in the LCF. Nor does a serum react with antigen no. 2 without reacting fully with antigen no. 1 (or no. 3). Marked differences between the reactions with antigens nos. 1 and 4 are, however, often seen. When such difference is qualitative (positive with one and negative with the other) the test should be repeated with (i) half the dose of the serum, and (ii) half the dose of the antigen. An increased reaction in either case would be a paradoxical reaction. The one with the decreased serum would be accepted as stronger than before inasmuch as an excess of the serum was interfering with its full development in the first instance. The one with the decreased antigen would still be doubtful

inasmuch as a relative deficiency in the serum (deficiency of the reagin, in quantity or quality) was interfering with its full development in the first instance. Exclusion of the paradoxical reaction is also necessary when known facts do not agree with the reaction and are thus anomalous in another sense.

An anomalous reaction in the case of the cerebrospinal fluid is excluded by halving the antigen only.

Two Uses of Antigen No. 3

Antigen no. 3 is used when antigen no. 1 fails with a cholesterol-fast complement. It is also used as a specially sensitive antigen for clinically known cases. The MHD of the complement is taken from the titration carried out in the presence of the antigen.

Reactions of Bordet's Antigen

This antigen gives the same reaction as antigen no. 1 with a complement of optimal reaction and of low or optimal titre, and a better reaction with a cholesterol-fast complement. When in the adjustment for high titre complement and cholesterol-fast complement the total quantity of the complement for the other antigen is reduced, its reaction may be slightly reduced. Antigen no. 3 gives a higher reaction than Bordet's antigen always. Antigen no. 1 adjusted with respect to cholesterol, for cholesterol-shy complement, varies in its reaction when compared with Bordet's antigen for optimal adjustment, overadjustment and underadjustment; the reaction is the same, lower and higher respectively, without adjustments for the quality of the complement for the other antigen.

Bordet's antigen cannot be improved much by concentration of the extract. A point is soon reached beyond which the reaction decreases. A slight improvement can be brought about by adding to the extract solid cholesterol instead of an alcoholic solution of it which dilutes the extract. (Instead of extract 30 c.c. + 1 per cent cholesterol 20 c.c. take extract 50 c.c. + cholesterol 0.2 gramme.) For an appreciable improvement in the stock, the selection must be strict and must be made from several dozens of extracts.

Bordet's antigen works with complements of all qualities (excepting the very cholesterol-shy complement) without giving any indication of the qualities on which depends the degree of fixation, although the dependence is more marked with other antigens than with Bordet's antigen. This is the main fault in the antigen. It should not be used alone.

Preparation of Titrated Positive Controls

All sera giving +++ reactions are pooled in lots of 25. They provide stronger controls than the pooled sera from cases of florid secondary syphilis mentioned before.

Quantities of Materials

The serum.—A quantity convenient for dilution is 0.5 c.c. 0.4 c.c. and 0.3 c.c. can be tested (will not be a part of the routine in dilution). A quantity under 0.3 is not sufficient for the full test described. The absolute minimum for the minimal number of tubes (one for the control and one for the test proper) is 0.1 c.c., with the standard volume. 'Positive, degree unknown', 'doubtful' or 'negative' will be the results reported. In special cases a full test can be carried out with 0.1 c.c., with a microtechnique.

The quantity of choice is 2 c.c. or more. With this quantity in hand (i) a test can be repeated, (ii) controls for the future can be kept and (iii) a stock can be built of human sera wanted in a serological laboratory for purposes other than the LCF reaction for syphilis. Blood drawn with a 5 c.c. syringe provides enough serum.

The cerebrospinal fluid.—2.75 c.c. will be actually delivered in 7 tubes. A quantity under 3 c.c. will not be sufficient for the full test described. The absolute minimum for the minimal number of tubes (one for the control and two for the test proper) is 1.25 c.c., with a standard volume. 'Positive, degree unknown', 'doubtful' or 'negative' will be the results reported. In special cases a full test can be carried out with 1.1 c.c., with a microtechnique.

The reagents used in 100 tests. (1) *The complement.*—The quantity varies with the titre from 6 c.c. to 24 c.c. The titre varies with the seasons. Occasionally sudden rises and falls distributed over 3 to 4 days due to sudden meteorological changes occur and upset calculation.

(2) *The hæmolytic amboceptor (for 150 c.c. of rbc suspension).*—The quantity varies with the titre from 0.75 c.c. to 0.075 c.c.

(3) *Antigen no. 1.*—3.4 c.c. of the extract is taken. 0.4 c.c. is added for the titration of the complement in the presence of the antigen (total 3.8). No. 3 antigen, if indicated by the titration, is only no. 1 antigen further modified.

(4) *Antigen no. 2.*—1.8 c.c. of the extract is taken.

(5) *Antigen no. 4.*—0.5 c.c. of the extract is taken. 0.1 c.c. is added for the titration of the complement in the presence of the antigen.

(6) *Packed rbc.*—4.5 c.c. will be required.

For smaller number of tests the quantities are proportional, excluding the quantities of the antigen taken for the titration of the complement in their presence.

The complement and rbc suspension are taken in excess of the needs of the 100 tests. They are used in other complement-fixation tests which are linked to the LCF test (*vide infra*).

Special Features of the Technique

There are five such features: (1) Qualities in complement and consequent adjustments in

the antigen-complement system. (2) Standardization of antigens. (3) Use of several antigens. (4) A qualitatively different +++ reaction. (5) Titrated positive controls.

A Mirror of Hospital Practice

A CASE OF AMCEBOMA WITH ABSCESS FORMATION FOLLOWED BY INFECTION OF THE DRAINAGE WOUND

By A. INNES COX, O.B.E.

LIEUTENANT-COLONEL, I.M.S.

and

ACHUTON

Government Hospital, Oolacamund

On the 26th of December 1946, a patient, who had been long resident in a hot and wet part of India, was sent into this hospital by a local practitioner with a tentative diagnosis of chronic appendicular abscess.

At the time of admission, the patient complained of slight pain and discomfort in the right flank and under the ribs in the right side where he was conscious of a tumour and a simple painless diarrhoea unrelated to the intake of food. These definite signs and symptoms of illness had been present for only one week. The previous history was only of bacillary dysentery and colitis during 1945; he had however been

feeling progressively 'off colour' for the past eighteen months. He had undergone treatment by many physicians and was sent to the Nilgiris to try the effect of rest and climate.

The patient, a wiry, highly strung nervous type, did not look ill. The abdomen, soft and easily palpable, showed comparative emptiness in the right iliac fossa, and a massive tumour in the right hypochondrium, that could be palpated through the flank behind like a kidney tumour, but there were no renal symptoms, nor had there been in the history any symptoms of renal disease.

The temperature was 98° and the pulse 100.

Renal tumour, tuberculous disease of the cæcum, chronic intussusception and appendicular abscess came easily to mind.

Renal disease was soon ruled out by a perfect pyelogram and by laboratory tests, so a barium series was taken which showed normality throughout except in the area of the tumour, which appeared to be the cæcum through which the opaque meal shot as it does in the case of tuberculosis of that organ.

Shadows of old calcified tuberculous glands in the abdomen were additional evidence for a diagnosis of tuberculous disease of the cæcum, and the blood count showing leucopænia added weight to the tuberculous theory as against that of appendicular abscess.

However, the possibility of chronic intussusception was kept in mind in spite of the fact that a highly intelligent and sensitive patient declared against ever having suffered a colic.

The case was clearly surgical, the probable diagnosis tuberculous disease of the cæcum and the plan of procedure, a first stage ileotransverse colostomy and a second stage resection.

At operation there was no evidence of tuberculous disease at all, nor indeed of intussusception, so the diseased area was packed off and the para-colic gutter explored by an attempt to mobilize the cæcum.

This presented considerable difficulty owing to the density of adhesions, but when achieved, more than a pint of pus was released from several pockets which, when broken down and explored, left a cavity; the posterior wall of which was the kidney, the anterior wall the massive thickened cæcum, and the superior wall the undersurface of the liver.

It was noticed that the pus was innocent of the typical *B. coli* smell but the condition appeared to be a chronic appendicular abscess, with the difference that there was no vestige of cæcal anatomy and that the walls of the abscess cavities instead of being smoothed out were granular and intensely vascular, so much so that much search for the appendix would have entailed considerable loss of blood. Hence sufficient tissue for biopsy was removed and the abscess cavity drained by a stab wound high in the flank posteriorly.

Resection of the bowel in such a supposedly septic state was not considered; hence after

careful toilet, the abdomen was closed and Dr. Achuton and I agreed to give a course of 6 grains of emetine during convalescence in case we had missed amoebiasis.

During a week's investigation before operation the temperature had been mostly normal, occasionally 99° and the pulse consistently 88 to 102 per minute.

After operation the pulse showed a maximum of 88 per minute and the temperature varied between 100° on the second day and 98.4° on the ninth when the stitches were removed from a cleanly healed wound. The discharge from the drainage stab however remained profuse.

On the 10th day the temperature rose with a rigor, so the stab drainage was explored with sinus forceps, and thereafter the temperature remained normal for nearly two weeks. Then further rigors, temperature and acceleration of the pulse heralded showers of pulmonary emboli. The patient was now seriously ill.

However in the course of 8 days he recovered from this misfortune except for a little blood-tinged sputum and all looked well but for the tumour and a discharge so profuse (being several ounces a day) as to give one cause to realize that the loss was more than could be compensated for by a capricious appetite.

The discharge was sanguineous and gangrenous and on microscopic examination showed nothing pathological as perhaps one should expect in dead tissue, neither had it the appearance of liver pus, and furthermore I had palpated the undersurface of the liver and found no breach on its surface.

Now the drainage wound began to look angry, and from it there extended a gangrenous patch which in a comparatively short time covered an area downwards and forwards equal to that of a large man's hand. The pulse quickened to 120 per minute and the temperature became irregular between 99° and 100°, while the blood-stained drainage discharge increased to such a degree that the condition of the patient deteriorated rapidly and an unhappy ending seemed inevitable.

Throughout the illness frequent stool examinations had been made, all with a negative result, and this, with the 'idea fixe' of appendicular abscess, albeit a peculiar one, somehow stunted originality of thought until a mental picture of something read in the past and half forgotten was recalled. Search found it in the *British Encyclopædia of Medicine*, 1941-42, under Amoebiasis Cutis wherein T. E. Syatt and R. R. Buckoly reported two cases, and were able to collect only 28 published cases. Of these it is stated, 15 recovered and 11 died. Reference to this small paragraph changed the diagnosis immediately and emetine was given with the determination to be bold about it, for without it there seemed no hope at all.

The result after 4 grains was dramatic. The dry black gangrenous skin began to separate like shoe leather, leaving a granulating wound

and a minimum discharge, debridement being unnecessary.

The tumour diminished in size, but remained palpable. The patient has now, in spite of his desperate state, received 9 grains of emetine on consecutive days, a rest for a week, and a further 4 grains. He is up and about, and although he still has his tumour, he is well.

What is to be the ultimate result of this? Will eventual resection or short circuit be necessary? He has never had signs of obstruction nor even ileus after operation. The pathological report of tissue removed for biopsy is, 'No appendicular tissue, specimen shows subacute inflammatory changes with congested blood vessels. No evidence of tuberculous infection'.

Yet clearly this was a case of amoebic granuloma, which is not uncommon. Many such cases have been written up by military surgeons practising in the East during the war. Moreover shortly after arriving at the correct diagnosis the *Indian Medical Gazette* of November 1946 published an article by Dr. D. Govinda Reddy, M.B., and Dr. C. Mohan Rangam on amoebic granuloma of the larger intestine describing six cases, but in none of these was the skin involved, neither can I recall reading of an amoebic granuloma with abscess formation followed by gross skin involvement as the result of drainage.

This case is not only of interest to us, but also gives one of us, Lieut.-Colonel A. I. Cox, an opportunity to correct an error in ætiology of this disease which was described by him in the *I.M.G.*, Vol. LXXVI, no. 11 of November 1941. Therein is described a 'tuberculous' cæcum which was not 'tuberculous' involving the terminal ileum, cæcum and appendix, the whole woody hard and intensely oedematous.

It was suggested then that the disease may be due to lymphogranuloma inguinale and the treatment excision with ileotransverse colostomy.

Lieut.-Colonel A. I. Cox went on to say that the specimens sent to the pathologist for cancer or tubercle proved the cause to be neither, and that unlike cases of tuberculosis or cancer, the resistance of such patients was so good that death was rare, so that verification by autopsy was seldom possible, etc.

What was described at that time must have been amoebic granuloma.

Skin infection is however rare, for why in all the resections that must have been done for this disease, has the skin not suffered? And why in so many liver aspirations does the skin escape? The answer, I presume, is that in the former, the procedure is complete and clean, the skin not being infected, while in the latter, the diagnosis is so obvious that emetine is always given. Yet there are many of us in practice to-day who remember that some 25 to 30 years ago amoebic abscesses were opened and drained, and not infrequently irritated by irrigation. It is regretted that skin section was not taken at

the advancing margin of the disease, so as to put the diagnosis on a sound basis, but to have suggested it would have been tantamount to asking the patient to quit hospital and fore-swear all further treatment.

In this case the amœboma had gone on to an abscess that precluded excision, and drainage with inadequate dosage of emetine resulted in gangrene of the skin, for peri-colic tissue had already been invaded by the amœbæ. Were I to recognize this condition again, I should do the minimum of opening and cleaning out the abscess so gently as to avoid any bleeding from the soft granulation tissue, then close the abdomen without drainage and put the patient on larger doses of emetine.

I should appreciate the views of other readers who may encounter this disease. Especially should I like to know the ultimate fate of such a case, which was little more than one of surgical diagnosis and medical treatment.

A CASE OF DIPHTHERITIC ENCEPHALITIS

By J. W. D. GOODALL, M.D., F.R.C.P. (Edin.)
MAJOR, I.M.S.

THERE are few references to encephalitis due to diphtheria in English medical literature and the condition is considered to be a rare one by Rolleston and Ronaldson (1940). A full description of a case in a child of eighteen months was given by Hall (1932) but apart from this the writer has not found it described except in foreign journals. The following case which occurred in his wards in the Medical College, Calcutta, may therefore be of interest:—

A Bengali Muslim female baby aged one year was admitted on 10th April, 1947. The mother stated that the child had suffered from fever for several days and that she brought her to hospital because she was now having convulsions.

On examination she was found to have a temperature around 99 to 100°F. There was a whitish grey patch on the right tonsil with slight cervical adenitis.

She was inclined to cough and had a running nose. The liver and spleen were not palpable, and the lungs showed no abnormality. The heart was normal except for tachycardia.

She was given 20,000 units of penicillin intrathecally and 20,000 units every 3 hours for 8 days. The throat and nose were also sprayed with penicillin, 1:500 units every 3 hours. Swabs were taken from the throat and nose and the nasal swabs showed the presence of *B. diphtheria* on three occasions between admission and 18th April. The throat swabs were all negative. Lumbar puncture revealed a clear fluid under slight pressure. A few cells all lymphocytes were seen. The protein value was 42 mg. per cent, the sugar 30 mg. per cent, and the chloride 675 mg. per cent. Subsequent estimations made in the course of the disease

showed no appreciable change except that the protein rose to 84 mg. per cent.

Progress.—Within a week of admission after a temporary improvement in the general condition the child began to vomit her food. Her weight began to fall. A fortnight after admission she became drowsy and could be handled without crying or waking. Irregular movements of the left arm and leg were noted but there was no paralysis. The eyes became vacant and staring at times but she could be roused for short periods. She continued to vomit her food.

Some rigidity of the back muscles was noted at this time but there was no definite neck rigidity. The reflexes were brisk. There was no clonus. Babinski's sign was not elicited. The abdominal reflex was absent. The temperature rose to 103°F. and the pulse was 120 to 160 per minute.

It was not till this stage that a diagnosis of encephalitis was made, and she was now given 40,000 units of anti-diphtheritic serum. She was also given a course of 7 days sulphadiazine in place of penicillin which was stopped for a week. No improvement took place. The left upper limb was noted as being weaker than the left on 1st May, and there was a slight degree of wasting of the left deltoid. No cranial nerve involvement was noted. The skull was x-rayed on 26th April, and showed no abnormality. The white cell count, which was done on 11th April, showed 31,000 leucocytes. The differential count was polymorphs 88 per cent, lymphocytes 10 per cent and mononuclears 2 per cent. Further searches in the cerebrospinal fluid revealed no tubercle bacilli.

The subsequent course of the illness was a steady decline accelerated by vomiting and malnutrition. Nasal feeding was resorted to. The patient died on 13th May.

Comment.—The main features of this case were the drowsiness, convulsions and vomiting associated with a high temperature towards the end, and with nasal swabs showing *B. diphtheria*. The patch on the throat cleared up in a few days after admission. No post mortem was held due to parental opposition.

SOME MISLEADING CASES OF HELMINTHIC INFESTATION

By B. B. RAI, M.B., B.S.

Medical Officer, Training Centre for the Demobilized Personnel, Bareilly, U. P.

Case 1.—Patient named Virendra, aged 3 years, from Nawabgunj, District Bareilly, was brought to the Centre with the following

symptoms. High fever (104°F.), frequency of watery stools, passing every five minutes, delirious and restless. On examination, the patient was thin, wasted, rather of rickety appearance, and pot-bellied. Tongue was coated with fur with angry-looking margins. Fine râles were heard in the lungs.

The abdomen was doughy and tender and there was tympanitis.

Stool did not show the presence of ova or cyst. on microscopical examination. Blood examination was: Total W.B.C. count 12,500 per c.c., polymorphs 65 per cent, lymphos 30 per cent, large monos 1.5 per cent and eosinos 3.5 per cent.

The duration of the disease was eight days. The patient was kept on the lines of anti-typhoid treatment. The diarrhoea, in spite of all dietetic precautions (the patient was kept on milk whey and *mussami* juice), medicinal aid persisted. Ice cap had to be applied for high fever and delirium, and plaster was applied for relieving the abdominal distress. After a week's confusion and anxiety, it was rather a surprise to find that the patient had passed a roundworm. He continued having hyperpyrexia, uneasiness and diarrhoea for the day, but in the evening the temperature dropped to normal, diarrhoea stopped and general condition improved.

Case 2.—Roop Kishore, aged 6 years, was brought with severe and distressing cough, high fever and delirium. On examination, the lungs showed the signs of acute bronchitis. Toxæmia was pretty high. The patient was a normal healthy boy otherwise. The child was kept on cibazol and glucose solution with plenty of water and fruit juice. Suddenly on the third day he passed three worms (*Ascaris*). Later on he was given santonin and he passed three more worms.

Case 3.—Bhagwan Das, aged 38 years, came to me in the evening at about 9 p.m. with severe abdominal colic. He was prescribed hot fomentations, and carminative mixture with bromides was given internally. He passed a restless night with bilious vomiting, which gave him relief for some time. On examination, there was nothing particular to give cause for anxiety. In the morning the patient vomited two big round worms.

Case 4.—Munno, aged 9 years, a total vegetarian and from an orthodox family, was brought with the complaint of blood in stools, the blood being scarlet red in colour and about a teaspoonful in quantity. On rectal examination an ulcer just an inch above the anus was found. After a week the patient developed an acute type of dysentery with tenesmus and fever. He was an average thin young child. The stool examination showed heavy infestation with tapeworms.

Comment.—From the cases referred to above and from general observation, it has been found that worm infestation, with roundworm in the first place and tapeworm in the second, is very common in Rohilkhand. The infestation is responsible for a very high

mortality (the patients mostly die before they are actually diagnosed in an ordinary practice, where the routine clinical examination is not possible) and the cases are diagnosed accidentally during the later stages of an acute illness. In many a case stool examination does not reveal ova or worms. The blood picture often is not of much help. Eosinophilia is not present invariably. It is a feature of the later stages.

Usually the signs and symptoms presented by the patients in the clinic are very misleading, specially when laboratory aid is not at command. The infestation is mostly found in children aged 2 to 13 years and more commonly in Mohammedan children.

SPONTANEOUS RUPTURE OF THE SPLEEN FOLLOWING AN ATTACK OF MALARIA : ITS CAUSES

By N. W. BILIANGADY, B.M.S.

*Superintendent, Beggars' Home for Males, Visapur,
Dist. Ahmednagar*

W. A., age 48 years, Northern Indian, was admitted to the Hospital of the Home on 29th March, 1947, for high fever with rigors the evening before. The spleen was not palpable. There was an epidemic of malaria here since December of last year. He was put on mepacrine one tablet three times a day.

In spite of mepacrine he continued to have the regular fever preceded by rigors. The temperature used to shoot up to 105°F. On the 30th, the spleen was palpable on deep inspiration. Next day it could be more easily palpated. On the 1st and 2nd of April it was readily felt a finger or two below the costal margin.

After three days of mepacrine treatment with no abatement of fever, five grains of quinine were given intravenously, mepacrine being continued. Even with quinine on the 1st of April the fever did not spare him. But next morning he was looking bright and feeling better. He relished his food and took ample rest throughout the afternoon, as he had no fever. That evening he was discharged, ordered to take a week's rest in his dormitory and his daily tablet of mepacrine for a fortnight from the outdoor.

On the third morning he was brought back to the dispensary for diarrhoea. It is said that he walked from his dormitory to the dispensary. The S.M.S. officer was sent for. Within five minutes the doctor hurried down, but before he could attend to him, the patient died. On enquiry it was found that he had passed a few watery motions in bed early in the morning and a few more after daybreak when his condition was taken notice of and he was carried to the hospital. After the post-mortem examination thorough investigations were made as to whether he had fallen or been injured while attempting to go to the latrine, or while being placed on

the examination table, or whether some of his companions nearby getting annoyed had hit him. It was learnt that nobody had worried him in spite of his creating nuisance and that he was carried to the hospital with all gentleness.

Post-mortem examination

The body was pale looking and the mouth and eyes were dry.

The thorax was opened only to find both lungs collapsed and the heart contracted without any blood in it.

As the abdomen was opened serous and sanguineous fluid flowed out. The abdomen was full of blood and clots. The spleen immediately attracted our attention, and its gastric surface was found covered with clots which came along with it when it was removed.

An irregular rent, running zigzag from the lower end of the hilum, was noticed after clearing the organ. It was 2 cm. long and half cm. broad and deep. A firm clot was covering it. As it was removed the rent became wider and deeper, exposing more of the splenic pulp. At the hilar end the lowest branch of the splenic artery with its corresponding vein was exposed and the peritoneal covering over it was also torn for 1½ cm. Immediately above the rent there was an oval area of 3 cm. long, a little puckered and depressed and presenting a yellow coloured web-like appearance. The gland was more friable than usual. Its surface looked as if there was a measly rash over it. The surface was shining. No other abnormality was seen. The dimensions of the spleen were 22 cm. in length, 14 cm. in breadth and 6 to 8 cm. in thickness. It was not weighed. The lower border was only one finger below the costal margin. A slice was removed from about the rent and was sent for pathological examination to ascertain the exact nature of the lesion.

Professor P. V. Gharpure, M.D., of the Grant Medical College, Bombay, has been kind enough to examine the specimen for us, and give his findings and opinion on it thus: 'Malarial spleen. Parasitized red blood cells seen in section. The rupture is spontaneous'.

The other organs were, as expected, pale looking besides showing a grey tinge about them.

Comments

The splenic tumour, whatever its nature, is notorious as the sword of Democles, ever hanging over the possessor, on account of its liability to rupture for little or no reason. But it is the large chronically enlarged spleens that have earned this bad name. Acutely enlarged organs may as well give way as in this case, though this mishap may be rare.

It is usually said that the cause of the rupture may not be obvious. Equally, obviously it seems that it is not sought for assiduously. In this case I believe that the diarrhoea led to the rupture. It may not be out of place if I draw attention to the severity of the diarrhoea that

some inmates suffer on account of their irremovably deep-rooted dirty habits. One of them even died after passing only two copious watery stools before anything could be done to him. This man was one of these dirty people. As seen from the notes on 2nd April, he evidently must have eaten more than he could possibly assimilate; thereby he might have had his death-dealing diarrhoea. On account of the forcible movements of the colon near about the splenic flexure, a certain amount of pull must have been exerted on the spleen through splenic end of the mesocolon. In diarrhoea movements must occur frequently, widely, and in rapid succession. The splenic flexure is one of the junctions of mobile and fixed parts of the colon. The mesocolon here rapidly becomes narrow and limits movement, thus making tugs due to movements all the more forcible. I think, therefore, that these repeated and strong pulls tore the spleen at the junction of an old fibrosed area with the rest of it. The spleen in that fresh condition was so friable that even gentle pressure by two fingers could tear the capsule. Hence it is not difficult to understand the fatal outcome in this case.

Besides, the patient probably got nervous on account of the diarrhoea. The nervousness might have induced the gland to contract. The contraction may, again, be due to a reduction in the blood volume caused by rapid evacuations. Normal areas contract and fibrosed ones do not. Such uneven contractions may lead to rupture, as a hot piece of glass cracks by the mere touch of a drop of water. The spleen may be said to be hot and brittle in conditions like malaria in the sense that it is more fragile than otherwise with distended and thinned out capsule under tension.

Should this explanation of mine be acceptable, some of the customary lines of treatment will have to be revised. The routine administration of an aperient for every case of malaria would become questionable as it is already with regard to several other conditions, especially surgical ones. And this caution may have to be exercised for a long time after the attack. The recently advised adrenaline therapy for reducing the size of the spleen will have to be viewed suspiciously if all causes that make the spleen contract are to be taken seriously into account.

It would be advisable to keep the patient in bed and watch him, just as for cases of injuries to the head. During and after a febrile attack, any sudden collapse shall have to be seen by a surgeon in good time, for such a spleen bursting spells rapid death in a few minutes. Only recently I witnessed a case of ruptured spleen dying within hardly 10 minutes of the receipt of a fist blow not very seriously inflicted over the splenic region. Immediate operation may have to be proceeded with merely on the suspicion that such a thing is possible.

My experience of malaria, in this place notorious for it, is that quinine, intravenously,

very quickly controls the disease, more quickly than do mepaerine and quinine itself by mouth or intramuscularly. It is not dangerous if old men, pregnant women and cardiac cases are avoided. If well diluted and slowly injected, it is harmless to the vein, and for the same reason, absolutely painless. Popularization of intravenous use of quinine would go a long way in preventing such catastrophies.

TREATMENT OF SCABIES WITH D.D.T.

By (Miss) D. HARI, M.B., B.S., L.M. (Dub.)
Zenana Medical Officer, Rajkot

In the outdoor department of this hospital several women bring children covered with lesions of scabies not only on hands and feet but all over the body.

In April, a Mohammedan lady came with two girls; all three had scabies. The itching was so bad, she said, that they could not sleep. She asked for an instantaneous cure.

Scabies being a parasitic infection I tried D.D.T.

I just dipped a swab stick in D.D.T. and touched every sore and every yellow point with it. Then I gave them potassium permanganate (gr. 2) and advised them to go home and take a hot bath with the lotion.

Next day they all turned up quite cured, looking well and clean.

After this I tried this on my servant's children who were suffering for a long time with scabies with amazing results. Ever since then I used D.D.T. for scabies and it is our routine treatment now.

Therapeutic Notes

NOTES ON SOME REMEDIES

XII. ANTIMONY AND ITS DERIVATIVES (Part III)

By R. N. CHAUDHURI, M.B. (Cal.), M.R.C.P. (Edin.),
T.D.D. (Wales), F.S.M.F.

(From the Department of Tropical Medicine, School of Tropical Medicine, Calcutta)

II. SCHISTOSOMIASIS

THREE distinct, but closely allied, diseases are produced by certain nematodes of the family Schistosomidae which gain entrance into the human body through the skin and inhabit the venous system, causing lesions in the bladder, intestine or liver.

1. *Urinary schistosomiasis*.—This is due to *S. haematobium*, the eggs of which, being

deposited in the mucous membrane of the bladder, give rise to hæmaturia and cystitis, and occasionally when deposited in the rectum, to mucæo-sanguineous discharges from the bowel. It is very common in Egypt and many other parts of Africa. A number of cases were observed among African troops stationed in Assam during the last war.

2. *Intestinal schistosomiasis*.—This is due to *S. mansoni* and affects the rectum and sigmoid and to a less extent the liver. It gives rise to diarrhoea or dysentery-like symptoms and may be complicated by cirrhosis of the liver and enlargement of the spleen known as Egyptian splenomegaly. It is widely distributed in Africa and may co-exist with the first variety. It is found in South America also.

3. *Asiatic schistosomiasis*.—This occurs in Eastern Asia. It resembles the intestinal variety in the earlier stages but has a greater tendency to produce enlargement of the spleen and cirrhotic changes in the liver.

Treatment

1. *Tartar emetic*.—It is given as in kala-azar but it is customary to start with $\frac{1}{2}$ grain dissolved in 6 c.c. of distilled water and gradually increase the amount by $\frac{1}{2}$ grain till the maximum dose of 2 to $2\frac{1}{2}$ (in children 1 grain) is reached. A total of 25 to 30 grains in adults and 10 grains in children spread over 4 to 6 weeks is usually sufficient. *S. mansoni* is more difficult to extirpate and requires larger doses up to a total of 50 grains.

The effects of the treatment in uncomplicated cases are striking. After a few injections the vesical pain and the scalding sensation disappear and the urine clears up, and in the early stages of *S. mansoni* and *S. japonicum* the blood in the faeces decreases and the toxic symptoms improve. The ova become shrunken, shrivelled and blackish and at the end of the third week all of them are usually dead. In severe cases dead ova may be passed intermittently for weeks and months after the parent worms are dead. The percentage of cure is about 90.

2. *Anthiomaline*.—This is more efficacious than tartar emetic and can be given intravenously and intramuscularly. It is supplied in 2 c.c. ampoules of a 6 per cent solution. Injection is given every second or third day, commencing with 1.5 c.c. and increasing by 1 c.c. until the average adult dose of 4 c.c. is reached. This dose is then continued until a total of 65 c.c. has been given. The dose for a child of 12 is half that of an adult.

3. *Neoantimosan (Fouadin)*.—This drug which is used in Egypt is put up in 6.3 per cent solution in ampoules and is given intramuscularly. The dosage recommended is: first day 1.5 c.c.; second 3.5 c.c.; third 5 c.c.; thereafter the last dose is continued on alternate days up to the 15th day. It gives a greater cure rate than

tartar emetic (about 97 per cent) but sometimes produces severe sickness.

The *pentavalent compounds* do not seem to be so efficacious in schistosomiasis as the drugs mentioned above. As in kala-azar, it is necessary to give the full course of treatment, otherwise all the parasites and the eggs may not be killed and there will be relapses. Relapses are also likely to occur if the treatment is interrupted for a week or longer. When they do occur, the treatment should be repeated. Some cases resist normal treatment; this is said to occur in persons whose excretion of the drug is exceptionally quick, so that it does not get a chance to act. The specific therapy is applicable to all three forms of schistosomiasis, but it should be remembered that antimony attacks only the living parasites and has no effect on the gross changes that occur in the advanced stages of the disease. These may be in the form of urinary fistula or stone in the bladder in the urinary form and troublesome rectal growths in the intestinal form. These are however amenable to surgical treatment. Removal of the spleen is called for where splenomegaly is a marked feature, but little can be done for the hepatic cirrhosis which occurs in the late stage of the Far Eastern variety.

III. TRYPANOSOMIASIS

The chief remedies for this condition are Antrypol (Bayer 205), Pentamidine (M.&B. 800) and Tryparsamide. Antimony has the disadvantage of being quickly excreted from the body and cannot be relied alone for a disease which is very chronic in nature and liable to relapse even after long absence of the parasites from the peripheral blood. But it is still used for its synergic effect. Moreover, the trypanosomes have a tendency to become drug-fast, and when once a relapse has taken place after an initial course of treatment with antrypol or tryparsamide, it is unwise to persist with larger doses, but a change should be made to remedies of different nature. Thus, antimony may be given to resistant cases or alternately with other drugs to accentuate their effects. Tartar emetic or antihomaline may be used as already indicated.

IV. LYMPHOGRANULOMA INGUINALE (CLIMATIC BUBO)

This virus infection which is acquired by sexual intercourse causes in the males inflammation of the inguinal glands and in the females pelvic lymphadenitis producing inflammatory lesions of the rectum. The disorganization of the lymphatic structures may lead to elephantiasis of the genitalia.

Both antihomaline and tartar emetic have been used but in smaller doses—the former with the initial dose of 0.5 c.c. increased by 0.5 c.c. up to 2 c.c., total of 10 or more injections; and the latter requiring 8 to 15 injections of 5 to 10 c.c.

of a 1 per cent solution. To be successful they must be given before the glands begin to suppurate.

The sulphonamides have a more definite value in this disease (vide *Indian Medical Gazette*, Vol. 82, No. 3, March 1947, p. 132). In presence of complications like rectal stricture there may be need for local measures such as dilatation, etc.

The value of treatment by drugs is, according to Manson-Bahr, enhanced by protein-shock therapy especially when suppuration has commenced. T.A.B. vaccine is employed, starting with 50 millions given intravenously and gradually increasing to 200 to 300 millions, injections being given every third day. The gland should be aspirated if there is suppuration. After 2 or 3 injections the buboes usually begin to dry up.

V. GRANULOMA VENEREUM

This chronic disease is of venereal origin and usually involves the genitals or the adjacent parts, being characterized by ulceration with a spreading granulation surface while at the same time tending towards partial cicatrization. The lymphatic glands are usually not affected. The causative organism is believed to be the Donovan body, gram-negative capsulated organism occurring within large mononuclear cells in the scrapings from the active borders of the lesions.

Of the many methods of treatment antimony probably gives the best results. Ten or twelve injections of 1 per cent solution of tartar emetic, beginning with 5 c.c. and increasing to 10 c.c., may clear up the lesions. Neostibosan and foudain are considered more efficacious. The early cases (i.e. within the first six months) respond quickly to antimony, but the progressive ones require more than one course of treatment and a few remain resistant. The treatment may be combined with x-rays and with protein-shock therapy.

Manson-Bahr advises daily dressing of the open granulations with a 1 per cent tartar emetic ointment, leaving it on the sore for 2 hours and then washing it off and applying boracic ointment. Rapid healing is sometimes ensured when podophyllin is used locally. After first cleaning the lesions with hydrogen peroxide, 20 per cent of the resin in olive or castor oil is applied twice daily, preceded by the application of a local anaesthetic to prevent any pain. When the exuberant granulations disappear, podophyllin is discontinued and scarlet-red ointment is applied to stimulate epithelization. Another local application is a sterilized suspension of zinc peroxide in distilled water, its activity depending on the liberation of oxygen. It is rubbed into the sore.

The sulphonamides are of doubtful value and penicillin has no direct therapeutic effect but may be valuable in cleaning up the secondary infection and allowing the specific treatment with antimony to be more effective.

TESTS ENDORSE BOVRIL CLAIMS

Most effective gastric stimulant

For over 50 years Bovril has been regarded by the Public as a body-builder, a stimulant and a standby in all cases of weakness. This faith in Bovril was, and is, based on the finest of all proof—personal experience. But it is natural that the exact reasons for the unique powers of Bovril should have been investigated, and experiments have from time to time been carried out by the medical profession.

In 1911, the late Professor Thompson, of Dublin, established that Bovril had the power of ministering to nutrition by the assistance it gave to the assimilation of other foods. Recently a remarkable series of experiments has been conducted at an English University. A group of medical students volunteered to undergo the unpleasant experience of allowing the passage of an œsophageal tube into the stomach so that accurate studies might be made of the effect of

certain beef preparations. One of the substances investigated was Bovril.

As a result of these experiments (described in detail in the *British Medical Journal* of August 28th, 1937) Bovril emerged as 'the most effective stimulant.' Briefly, it was proved that Bovril increased the supply of gastric juices where there was a deficiency and restored it to normal. It is an accepted medical fact that people of sedentary habits generally suffer from a lowering of the essential gastric activity; Bovril rectifies this and, by facilitating the digestion of proteins, enables full nourishment to be gained.

Everyone, therefore, who is run down through strain or illness, or who feels in need of extra strength to cope with the demands of modern life, should take a cup of hot Bovril daily. It is a delicious and stimulating way of keeping fit and strong.

BOVRIL

STIMULATES DIGESTION

THE NEUTRALIZATION OF EXCESS ACIDITY

In conditions where eupepsia is lacking, with consequent gastric and intestinal disturbances, Cal-Bis-Ma is indicated. Cal-Bis-Ma has demonstrated its usefulness as a gastric antacid in minor gastric upsets. For the control of excessive acidity and as a protective in peptic ulcer, as well as a gastric sedative in simple nausea of pregnancy (morning sickness), Cal-Bis-Ma has achieved a reputation of its own with many physicians who have found that Cal-Bis-Ma meets the situation in a most substantial manner.

MULTIVITE

Trade Mark

Presenting Vitamins A B₁ C and D in a single pellet

The most satisfactory results are obtained when the vitamins are administered in a group. The rational explanation for this is based upon the following facts :—

1. Uncomplicated deficiencies of a single vitamin are rare.
2. The effects of incorrect proportions of vitamins taken are second only in seriousness to those of marked deficiencies.
3. Efficient utilisation of individual vitamins is in many cases dependent upon the presence of other vitamins in adequate amounts.

Multivite pellets are the original preparation in which fat-soluble and water-soluble vitamins are combined in one compact palatable product. They constitute an acceptable means of supplementing the vitamin intake from the diet and of preventing the appearance of deficiency symptoms of the four principal vitamins, A B₁ C and D.

Stocks of Multivite are held by leading chemists and full particulars are obtainable from—

SEPTEMBER

PLANNED PARENTHOOD

THIS expression or FAMILY PLANNING is an euphemism for birth control in the West. Additions to the family occur according to a plan based on the financial status of the parents mostly and on their health occasionally. In the East generally and in India particularly these expressions also find application but denote quite a different state of affairs. The parenthood here is planned by the grand-parents of the additions. They arrange marriages between boys and girls usually before puberty. Not long ago most of such marriages actually were entered into (= solemnized) also long before puberty. In a specially surveyed area in Bengal the average girl-wife to-day cohabits at 12.7 and presents her addition to the family at 16 (Lal and Seal, 1946).

The girl, it is argued, is not only married to the boy but also adopted into the family at a tender and an impressionable age. The traditions of the family are thus handed down not only by the father to the son but also by the mother-in-law to the daughter-in-law. The result is a portrait gallery of long lines of ancestors always present before the mental eye. The ancestors provide the precept and the model. The future to an Easterner is only the past entering through another door. On such a basis rests the foundation of the Eastern culture which, with all its faults, teaches how to live and let live, as opposed to the Western culture which only teaches how to live.

While China and India with their ancient civilization remain what they were before Greece and Rome rose and fell, before Christianity was born, 'within historical times at least three civilizations have risen and fallen in the West. Within comparatively recent times great powers have sunk into obscurity and a nation born only two hundred years ago dominates the world to-day' (Parkes, 1946). So much for the bright side of the culture which teaches how to live and let live. There is a dark side also.

Concentration on the past and the future ignores the present in spite of Confucius. The joy of living is replaced by rituals. Even sex becomes a duty. A son must marry to beget a son. A daughter must be married to give someone a son. A characteristic state of inertia, containing amongst other ingredients an overwhelmingly large percentage of resignation and boredom, overpowers the nations whose masses become hewers of wood and drawers of water, to adventurers of their own land or from abroad. Thus has lived Asia almost from the dawn of Asian civilization. Life at any cost even at the cost of human pride and self

respect. Even under congenial circumstances the life is reduced to the minimum, leading to joint families and lowering of the standard of living. The masses of Asia differ from those of Europe. They specialize in organizing poverty and equalizing misery.

The lower standard of living and enforced duty to sex have given rise to a population pressure which has been enhanced in recent times by modern sanitation. The higher the population pressure the lower the standard of living, the lower the standard of living the higher the population pressure: so runs the vicious circle.

Westerners who are also feeling the population pressure are finding it difficult to reduce it or to reduce it satisfactorily by planning parenthood. The planning is undertaken by the population with a high intelligence quotient while the one with a low I.Q. breeds unchecked. The result: a general lowering of I.Q. for certain. 'We are told that if the present drift is maintained it will result in a drop of nearly two points in the Binet I.Q. between the average of one generation and that of the next. If this is true and continues we shall see human mentality reduced below that of the apes before we have recovered from the last war' (Notes and Comments, 1947). The planning may not reduce the pressure appreciably and is definitely dysgenic in its operation.

From America comes the same tale of woe: 'It is shown that college graduates and high-school graduates had underreplaced themselves by 45 per cent and 21 per cent, respectively, while those with only one to four years of grade school had overreplaced themselves by 95 per cent. Also, it was found that the lowest economic third of our families have overreplaced by 76 per cent, while the highest economic third has underreplaced by 19 per cent' (Editorial, 1947).

The giving up of our system of planning parenthood, on the other hand, is bound to be fruitful. It will decrease the population pressure and increase our I.Q. at the same time. The population which plans the most contributes to the quotient the least. And it may be possible to persuade it to give up the planning. The masses are at present buoyed up by the spirit of independence and will do many things for their leaders, even if they refuse to turn the other cheek in obedience to vespers exhortations, at times.

The usual methods of the Western type of planning will not even work universally in our country, because of poverty, lack of privacy, and tropical deterioration in the usual material employed. Even in the West they do not appear to be crowned with unqualified success (Editorial, 1946). The 'safe period' may be studied and employed. A few years ago this method fell into disfavour. But recently it has found favour again with the authorities on the subject. (Hyman, 1947). Even if it fails in individual cases it will succeed on the whole and

serve its purpose fully. If necessary, the law should be amended to legalize measures which though not unethical to the majority of the population are illegal because of old European prejudices. (The British Government Committee on Abortion, 1947). Such an aid to the handicapped woman has been rendered elsewhere for many years now (Haire, 1947) without any appreciable injury to the physique, prestige or pride. The unwanted children passing through the stage of problem children give rise to problem families which in a nation's life, in peace time, are not less dangerous than fifth columnists during a war. Not a small fraction of a large section of our population consists of unwanted children born of boredom alone.

Removal of the boredom itself, by providing healthy recreation and sports, will limit the population directly. The appreciation of leisure is inseparable from the appreciation of the good things of life. The latter appreciation convinces one of the futility of lives lived at low levels, raises the standard of living and thus limits the population indirectly. That happiness in this world does not interfere much with the enjoyment of the next, could also be a part of the plan and be made plain to the masses now who have become radio conscious. They will listen to suitably selected folk-lore rich in wit, humour and pathos. For the older generation a mixture with theocracy may be necessary. There is no harm in such a mixture. It will not be required for long. Even if it is one does not mind: England is theocratic and so is one of the twins born of the British Empire.

At this juncture all things are possible and we see a great future before the nation. Even the unfortunate wave of fratricide shows that the worm at last has turned. The stupidity of killing one's neighbour, of one's own race, who speaks the same language, sings the same songs and eats the same food, for differences which do not concern this life at all, will soon be realized and by then the worm will no longer be a prone and helpless dweller in the slimy ruts of ages in which Asia abounds. Cases of Asian Torpor are recovering by crisis and passing through a phase of mental symptoms. All is going to be well with them soon.

TRANSMISSION OF KALA-AZAR IN INDIA. THE CASE AGAINST THE SANDFLY. A REJOINDER

By R. H. MALONE, M.D., D.P.H. (McGill)
LIEUTENANT-COLONEL, I.M.S. (Retd.)

A SPECIAL article has recently appeared in the *Indian Medical Gazette* (Shortt, 1946) which purports to be a reply to our paper on the transmission of kala-azar published in the issue of October 1944 (Malone and Brooks, 1944).

If this reply is the 'complete refutation' of our assertions referred to by the writer in his paper read at the meeting of the Royal Society of Tropical Medicine held on 17th May, 1945, it has signally failed in its purpose.

Before replying to his criticisms the case may briefly be restated:—

Swaminath, Shortt and Anderson (1942) succeeded in transmitting kala-azar to human volunteers by the bites of *P. argentipes* bred and reared under the following experimental conditions; laboratory-bred flies were fed on suitable kala-azar patients; they were reared in globular glass chimneys at a temperature of about 28°C. and fed on raisin juice; their life was prolonged to 10 days or longer and during this time the flagellates multiplied and extended into the pharynx and buccal cavity, a considerable proportion of flies becoming 'blocked'. They were then fed on human volunteers who later developed kala-azar.

This experiment, it is claimed, provides the final proof that *P. argentipes* is the true vector of kala-azar in nature.

Our contention was that the experiment had been carried out under conditions which do not obtain in nature; that the prolonged life of the flies, the pullulation of the flagellates into the pharynx and buccal cavity, and their 'virulence' were all due to the particular conditions under which the flies were bred, reared and fed in the laboratory; and, consequently, the final proof of transmission by the sandfly in nature is still lacking. We supported our contention with arguments based on:—

1. Our present knowledge of the bionomics of *P. argentipes* in nature.

2. Certain epidemiological observations which, in our opinion, could not be reconciled with the theory of transmission by a biting insect.

In our paper we stated that there is no proof that in nature the sandfly lives for longer than 6 days, nor that it takes more than one blood

meal, nor that it ever indulges in raisin juice or plant juices of any other kind.

Since these phenomena appear to be essential for the experimental transmission of kala-azar by sandflies, the supporters of the sandfly transmission theory must show, in order to prove their case, that our statements are incorrect or demonstrate that the experimental conditions under which successful transmission became possible were similar in all essentials to those obtaining in nature.

Thus Shortt attempts to show—

1. That the sandflies live for 10 days or longer in nature, and therefore must have fed more than once.

2. That there is presumptive evidence that they feed on plant juices in nature, since this is a normal procedure in the rearing of laboratory-bred sandflies and mosquitoes.

3. That in other respects, especially with regard to temperature and humidity, the experimental conditions were similar to those obtaining in nature.

4. That, as a corollary, a duration of life of 10 days or longer, the indulgence in a second blood meal and the ability to infect which occurred under those conditions must also occur in nature.

We consider this to be a fair statement of the case and may now proceed to deal with the points raised in Shortt's paper, his criticisms and objections.

Duration of life of P. argentipes

In his attempt to show that sandflies live for 10 days or longer in nature the writer criticizes our interpretation of the results of experiments carried out by Smith *et al.* (1936) in which flies were marked, released and then searched for on successive days after release. He states: 'In their comments it has suited the authors to ignore the previous experiments of Smith *et al.*, where, out of a much smaller number of flies (667) released, recoveries of marked flies were made up to the fifteenth day. Our knowledge of the physiology of the sandfly makes it certain that such flies must have fed a minimum of three times to live for so long a period'.

This statement is incorrect, it is misleading, and it begs the question.

So far from ignoring Smith's experiment we made full reference to these 667 flies, included the author's table showing daily recoveries of marked flies and commented on the possible

fallacy in one of the methods of identification (*viz.*, the removal of one middle leg in so delicate an insect) used in this experiment which, we suggested, led to its being abandoned in later experiments.

To say that in this experiment recoveries of marked flies were made up to the 15th day is misleading. Flies were recovered on the 3rd, 4th and 7th days and not again until the 15th day: none was recovered on the 1st, 2nd, 5th and 6th days.

It is clear that little reliance should be placed on this experiment, on account of one of the methods of identification employed, the relatively small number of flies released, the low recovery rate (1.4 per cent) and the irregularity of the catches. In the later series (after a reliable method of identification had been introduced) 3,271 marked flies were released: the recovery rate was 3.6 per cent: catches were made (*in decreasing numbers*) on every day from the 1st to the 6th and *not afterwards*.

We rightly considered that much more reliance should be placed on the latter series of experiments than on the former.

Shortt assumes that the two flies caught on the 15th day in this obviously imperfect experiment were genuine 'marked' flies, and on this assumption (which requires proof) remarks that they 'must have fed a minimum of three times to live for so long a period'. This is simply begging the question and should, on no account, be taken as evidence that the sandfly feeds on more than one occasion in nature.

This type of experiment was continued in 1937, 1938 and 1940 and there is no record of a single marked fly having been recovered after the 5th day following release (Report of the Scientific Advisory Board, Indian Research Fund Association, 1937, 1938 and 1940). The figures for daily recoveries of marked flies are not given in the 1937 and 1938 reports, but in the report for 1940 it is stated: 'Of 810 flies marked and released 25 were recovered, the majority were captured on the 1st and 2nd days after release and only one was found on the 5th day. These results are very similar to those obtained in 1934. . . .'

It may be of interest to the reader to compare the results of the three experiments referred to above.

This disposes of the claim that there is evidence to prove that the flies live for 10 days or longer in nature.

Experiment	Number of marked flies released	Number of marked flies recovered daily										Total	Percentage of recoveries
		1st	2nd	3rd	4th	5th	6th	7th	...	15th			
1	667			1	2			4	..	2	9	1.4	
2	3,271	79	18	9	7	2	3	118	3.6	
3	810			24		1	25	3.1	

(The majority on the 1st and 2nd days)

Further on in the section dealing with the duration of life and feeding habits of *P. argentipes* the writer states:—

'In quoting the opinion of Shortt *et al.* (1932) that in performing the act of fertilization the males die, having paid their full debt to nature, they go on to say "It is probable that in ovipositing the female also pays her full debt to nature". In other words they imply that the female is intended to lay eggs once and then die'.

In his quotation from our article, the writer has omitted the concluding part of our sentence, which was: '*as suggested by the work of Christophers et al. (1926) quoted above* (italicized now for the benefit of the careless reader).

It is obvious that we were not 'quoting the opinion of Shortt *et al.* (1932)' but referring to two observations made by Christophers *et al.* (1926), *viz.*, that the flies invariably died immediately after ovipositing and that caught gravid flies never took a second meal. We suggested nothing more than that, *in nature*, the female sandfly as well as the male is short-lived and that once fertilized she does not require a second meal. The implication here is that the sandfly, *in nature*, lays only one batch of eggs. We had no intention of casting reflections on the egg-laying capacity of the writer's laboratory flies, but we must protest against the general tendency to argue from laboratory flies to wild flies as if the habits and behaviour of the former are necessarily identical with those of the latter.

He then goes on to make the following remarks (we may be pardoned for quoting them in full): 'If the authors had even a slight knowledge of the anatomy of the female sandfly they would know that each possessed an organ called a spermatheca, which on the act of fertilization, soon after the emergence of the fly, collects in it a large store of spermatozoa *intended to fertilize future batches of eggs* (author's italics). Were the sandfly intended to lay only one batch surely nature would not have gone to the trouble of supplying it with a special organ for the storage of spermatozoa which would never be used.'

Nature's intentions are not always so readily discernible. There are some insects (among the locusts, for instance) which possess a spermatheca and yet lay only one batch of eggs: others (among the moths, for example) which possess a spermatheca and yet live for a day or two only: and finally, there are species of *Drosophila* which possess a spermatheca, lay a single batch of eggs and die immediately after ovipositing. This is exactly what Christophers *et al.* (1926) and Napier and Smith (1926) observed in the case of *P. argentipes*.

The little lecture on Entomology, quoted above, with its almost pathetic appeal to teleology would have delighted the nineteenth century theologian: it will hardly satisfy the student of to-day.

The fallacy in the argument (contained in the words italicized by the present author) is obvious, yet Shortt would have his readers believe that 'this one fact would seem completely to demolish the structure of their argument'.

Feeding habits of P. argentipes

Two important considerations to be discussed in relation to the transmission of kala-azar are: (1) Do the sandflies take more than one blood meal in nature? and (2) do they feed on plant juices in their natural environment?

With regard to the first question. It was the opinion of Napier and Smith (1926) that the flies do not take more than one blood meal in nature and there is no evidence at the present time that they do. The onus of proof does not lie upon us and since Shortt has not attempted to refute our statement the question need not be discussed further. The argument that they can be induced to take more than one blood meal under certain laboratory conditions, and may therefore be presumed to do so in nature, will be dealt with later.

With regard to the second question. There is no evidence that the flies feed on plant juices in nature. I agree with the writer that 'it would be difficult to prove that flies never feed on plant juices under natural conditions', but here again the onus of proving that they do so does not lie on us. On the other hand there is presumptive evidence that they do not. (1) Attempts to capture flies in areas, not in the vicinity of houses or cattle sheds, where there is vegetation have been singularly unsuccessful. (2) There are some endemic areas of kala-azar where plant juices would appear to be well-nigh inaccessible to *P. argentipes*. Thus, Christophers (1926) notes that in parts of Madras where kala-azar is endemic 'so closely built are some of the houses that over considerable areas there are no spaces other than small paved yards and the street'. 'At Kayalpatnam the disease occurs in small solidly-built Mohammedan houses associated with a soil of pure sea sand'. (3) Shortt himself admits that plant juices are not the normal food, since the ovaries of the fly will not develop in those fed on plant juices from the beginning or subsequent to the first blood meal. This damaging admission will be discussed later.

Notwithstanding this admission he draws an analogy between mosquitoes and sandflies fed on raisins, as follows:

'In keeping mosquitoes for experimental work these methods of feeding on raisins or other plant juices is a normal procedure, but nobody has inferred from this that the mosquito would normally prefer plant juices to blood as its diet, and there seems no reason to suppose in the case of the sandfly any more than in that of the mosquito, that the normal food may not be blood, simply because the insect can be made to feed on plant juices. . . . 'A little more knowledge of the bionomics of insects in general, to say

nothing of *P. argentipes* in particular, would have deterred the authors from developing this argument'.

In the first place the analogy between mosquitoes and sandflies is false. Mosquitoes do not necessarily require a diet of plant juices in order to transmit malaria, while in the case of the sandfly, the diet of raisins appears to be absolutely essential for the transmission of kala-azar. Human transmission experiments carried out before this technique was adopted were entirely unsuccessful, even though the life of the flies had been prolonged by a technique similar in other respects. Thus, 'Eleven human volunteers were fed upon 11,537 times by flies which had previously been fed on kala-azar cases and re-fed two or more times to allow the infection fully to develop. These human experiments were entirely negative in spite of an intensity of feeding much greater than would ever occur in nature' (Shortt, 1946).

In the second place the writer (once more accusing us of lack of knowledge) implies that we believe plant juices to be the normal diet of the flies. Our contention was that *P. argentipes*, in nature, fed solely on blood and there was no proof that it ever fed on plant juices. But here we are not only accused of suggesting that the latter are the normal food but are then condemned for our ignorance in drawing an inference which we did not draw and developing an argument which we never even started.

We still maintain that there is no evidence to show that *P. argentipes* have more than one blood meal or ever feed on plant juices in nature.

Flagellate infections in P. argentipes

In reply to our statement that 'in 20 years of unremitting research not a single *P. argentipes* has ever been recorded with a natural infection of *L. donovani* extending to the pharynx or beyond', the writer states: 'The fallacies in this argument are only too obvious. In the first place the research for *P. argentipes* was by no means unremitting for twenty years, and in fact was only occasionally pursued'.

The exaggeration is admitted—Smith reported one case in 1935—but consider that the writer is guilty of an under-statement in the last words of the above quotation. Perhaps he will agree to the following amendment:—

'In spite of researches during which thousands of flies have been examined, only one *P. argentipes* has been discovered with a natural infection of *L. donovani* extending to the pharynx'.

The writer has unfortunately missed the point of our argument. Obviously, a pharynx infection will be extremely rare when infections of any degree are so rare in nature. The real question to which neither the writer nor anyone else has given a reply is: Why are instances of infection, to any degree, so remarkably few in nature, although thousands of flies have been examined, and when they can so readily be

produced in the laboratory? This is all the more difficult to understand, since the sandfly is a domestic insect and, according to Shortt, 'a certain percentage of infected flies must always be present in houses, harbouring kala-azar cases'.

In this connection we stated that the finding of 7 infected flies out of 226 examined (Shortt *et al.*, 1930) has sometimes led to the assumption that 3 per cent of wild flies caught in kala-azar areas are naturally infected.

Shortt states 'I do not know who makes this assumption but it was certainly not made by the Kala-azar Commission'. I can only say that I have heard this statement made by research workers during discussions on the transmission of kala-azar. And who should blame them? Here are three quotations taken from the published writings of members of the Kala-azar Commission:

1. At the same time it will be evident from the results that a certain percentage of infected flies must *always** be present in houses harbouring kala-azar cases (Shortt *et al.*, 1930).

2. The occurrence in nature of *P. argentipes* infected with *L. donovani*. 'This was demonstrated by the Commission with no special difficulty'. Out of 345 *P. argentipes* caught in kala-azar houses and dissected 8 were found to be infected with *L. donovani*' (Shortt *et al.*, 1932).

3. . . . a large percentage of the flies that feed on an infected person acquire the infection: infected flies have been found *repeatedly in nature** (Napier, 1943).

To-day, however, the writer states, ' . . . in all, the number found infected in nature could probably be counted on the fingers of both hands' (Shortt, 1946).

No further comment is necessary.

The writer then takes exception to our statement that 6 of the 7 flies referred to above were caught in a cattle shed and not in a kala-azar house. He states: 'They further state that six out of the seven flies were not caught as stated by Wenyon (1932) from kala-azar houses but in a cattle shed. Apart from this being an incorrect statement—Wenyon is correct—they again display ignorance of local conditions in Assamese houses. The cattle shed, as often as not, forms part of the house itself, and is normally always immediately adjoining it (our italics). It would be as easy, therefore, for the sandflies after feeding to come to rest in the animal as in the human part of the house'.

The writer's reply is unconvincing: 'The table attached to the original paper (Shortt *et al.*,

* Readers who are interested in this subject are advised to study the original papers as well as the Reports of the Kala-azar Commission. The latter contain abridged editions of the original papers (in addition to previously unpublished reports and reviews) and it sometimes happens that statements in the original, not considered important by the Commission but of value to the critics of the sandfly theory, have been omitted from the reports.

1930) specified ten areas from which *P. argentipes* were caught and examined and in only one instance is a cattle shed expressly mentioned. This is the area from which 6 of the 7 positive flies were captured. Since cattle sheds, as often as not, form part of the house or are normally always adjoining it, why was the cattle shed specifically mentioned at all? Furthermore, the explanation now given by Shortt is strangely at variance with that of Knowles who stated that Hindus suffered less from kala-azar than Mohammedans because Hindus kept cows, and that Lloyd and Napier (1930) had shown that '*P. argentipes* would feed every time by preference on bovine blood'. One wonders why this explanation was not immediately challenged by members of the Commission working in Assam.

This discussion is not simply an attempt to solve a childish riddle—'When is a cattle shed not a cattle shed?' It has an important bearing on the sandfly transmission theory. The writer's display of annoyance at our alleged display of ignorance and his brief but emphatic denial of Wenyon's error are apparently due to the fact that we implied (without expressly stating so) that the six infected flies may not have bitten a kala-azar patient at all, and therefore the flagellates found in them may not have been *Herpetomonas donovani* but some other herpetomonad, morphologically indistinguishable from them. In such an event the arguments used by Wenyon in his criticism of the bed bug transmission theory might be equally applicable here. Wenyon (1932), in writing of the bed bug reported positive by Mrs. Adie, stated: 'There was no evidence that the particular bug had fed upon a kala-azar case, nor that the flagellate observed was actually the kala-azar parasite which cannot be distinguished on morphological grounds from many purely insect flagellates occurring not only in the intestine but also in the body cavity, salivary glands and other organs of insects'.

Having answered Shortt's criticisms this section of the article may be concluded with the following statements:—

Flagellate infections are readily produced in laboratory flies. 'Though the parasite is so scantily found in the peripheral blood, yet with great regularity some 25 per cent of flies fed upon cases develop flagellate infections . . . ' (Christophers, 1926).

Flagellate infections are very rarely found in nature. 'The number of naturally infected *P. argentipes* found up to date is remarkably small and quite out of proportion to the incidence of the disease in endemic areas' (Smith *et al.*, 1941).

No satisfactory explanation for these dissimilar observations has been given by the exponents of the sandfly transmission theory.

Temperature conditions in the laboratory and in nature

One of the earlier devices used by the Kala-azar Commission for prolonging the life of their laboratory flies was segregation of the sexes. This was abandoned for various reasons (Shortt *et al.*, 1926). The writer now claims that this procedure was one of the 'temporary expedients' employed 'when less was known about the bionomics of the fly, and which were discontinued as soon as more natural methods of prolonging the life of the fly were substituted as a result of the study of the conditions under which the fly lived in nature' (Shortt, 1946). It appears, however, that the most important reason for finally abandoning this procedure was the discovery of a new technique which was less tedious and less open to objection. The essence of the new technique was the rigid control of the temperature (28°C. to 1) of the incubator in which the flies were housed. This technique was so successful in prolonging the life of the flies and in stimulating the multiplication of the flagellates that the investigators were eventually led to carry out their first, and unsuccessful, transmission experiments on human volunteers.

It is now claimed that this technique was the outcome of a study of the conditions under which the flies lived in nature: and that it was a deliberate attempt to reproduce the conditions prevailing in nature during the monsoon period, when reproduction of the fly in nature is actively in progress.

This is not in accordance with the published facts (Shortt *et al.*, 1926). The discovery was purely fortuitous and was due to the fact that in a particular part of a particular month of a particular year (the latter part of September 1925) the climatic conditions were such that the temperature of the unregulated incubator in which the flies were housed remained almost constantly between 27°C. and 29°C. Shortt states: ' . . . by September large numbers of bred flies were available for experimental feeding. Towards the latter end of this month the flies began to feed fairly freely under experimental conditions. It was now found that, unlike the conditions which had obtained last year, considerable numbers of flies successfully laid eggs and survived for further feeding. The conditions under which the flies were being kept were similar to those which obtained during our previous work except in one respect' . . . 'the only difference now introduced was purely fortuitous and due to climatic conditions, in that the room temperature now averaged about 28°C. whereas previously flies had been kept at about 26°C. to 27°C. or lower. This uniform temperature of 28°C. was found to be the important factor hitherto absent'.

I have no wish to detract from the acumen of these investigators in developing their new technique of rearing laboratory flies as the result of this chance occurrence, but must

* See footnote on previous page.

protest against the claim now made, that it was the outcome of the study of the flies in nature during the monsoon period. One of our main criticisms has been that little attention has been paid to the study of the flies in nature.

It is extremely unlikely that the uniform temperature of $28^{\circ}\text{C.} \pm 1$ (not ± 2 , as Shortt now states) which was artificially maintained in the incubators would obtain throughout the monsoon period, year after year, even though the temperature of the cracks and crannies in which the flies hide may be more uniform than that of the room.

There is also an unexplained difference between laboratory conditions and natural conditions. The Commission found that: 'The feeding of artificially bred *Phlebotomus argenteipes* can be carried out in Assam between the months of September and April inclusive, if bred flies are available. The period May to August appears to be climatically unsuitable in Assam, and whatever means be taken to encourage it, satisfactory feeding has not been found to be possible'. That is to say: During the months when wild flies are breeding freely in nature, laboratory flies will not feed satisfactorily, but when wild flies are more or less quiescent in nature, laboratory flies begin to wake up!

The alleged similarity between laboratory conditions and natural conditions

It is well known that the factors which govern the duration of life in insects are many and varied. The life of the adult female may be shortened or prolonged by such circumstances as the nature and quantity of the food available, the presence or absence of the correct larval food, variations in temperature and humidity, free or limited association of the sexes, the space allowed for movement and the facilities for mating and egg-laying. Life may be prolonged if the food be deficient in quality or amount, if the proper larval food be absent, and if opportunities for mating are denied. Temperature and humidity, life in a comparatively open space (e.g. an insectarium) or in a closed space (e.g. test tubes or glass globes) and other factors, but little understood, also play their part.

According to Maxwell-Lefroy (1909) 'Abundant food by hastening maturity and the development of the reproductive system may materially shorten the life of an insect; unnutritious food or the lack of food may immensely prolong life either by preventing the immature insect from deriving sufficient nutriment from its food or by checking the development of the reproductive organs, so that life is maintained for long periods until the eggs are formed and egg-laying becomes possible. The absence of the larval food-plant is another factor which prolongs the life of the adult, since the mother insect will remain alive until eggs are laid on the food-plant unless this period is so long as to exhaust her vitality'. Again the

same author states with reference to 'normally very short-lived insects such as many Diptera'.

'For these insects life may be long, but given the optimum temperature, plentiful food, abundant flies hatching out together and a suitable food supply for the young, on which the parent may lay eggs, the period is reduced to the least possible, the egg hatches quickly, the larva quickly lays up food, the transformation is quickly accomplished and the flies quickly find mates'.

Experts in the breeding and rearing of insects have devised various means for prolonging life in order to create conditions suitable for the particular investigation on which they are engaged. Nevertheless, in investigations such as those on kala-azar, where flies bred and reared under certain laboratory conditions prove to be successful transmitting agents, it is the duty of the investigators to show that the laboratory conditions under which the flies were bred and reared were similar in all essentials to the conditions obtaining in nature.

This has not been done by the protagonists of the sandfly transmission theory of kala-azar and indeed so little is known of the bionomics of the sandfly in nature that any claim to similarity in all essentials between laboratory and natural conditions can be nothing more than an assumption. We would go further and suggest that laboratory conditions were created, consciously or unconsciously, by accident or design, which were favourable to the development and multiplication of the parasite but quite unsuitable for the normal life of the sandfly (so far as this is known).

With the technique for breeding and rearing sandflies introduced by Smith in 1924 and modified by Christophers, Shortt and Barraud in 1925, the flies were bred and reared in the presence of larval food consisting of rabbit and goat faeces: the temperature was generally that of the room and the humidity regulated according to experience: the food was blood and the sexes were not segregated. With this technique the females, whether caught or bred in the laboratory, almost invariably died in the act of, or immediately after ovipositing, and very rarely lived longer than 5 days. This is in agreement with the results obtained by Smith when flies were marked, released and searched for on successive days after release. There are some grounds, therefore, for believing that these laboratory conditions were akin to those in nature.

At this stage in the investigations Christophers, Shortt and Barraud stated: 'We have paid considerable attention to making conditions as favourable as possible to the flies and have tried open nets and large and small confined spaces, with various devices and under various conditions of temperature, but without being able to prolong life beyond the periods noted'.

At this time infections of the gut were not infrequently observed but there was little

evidence of the much-to-be-desired 'anterior development' of the flagellates; and so the life of the fly had to be prolonged in order to permit the flagellates to develop fully.

From now onwards the fly is treated more as a laboratory instrument than an organism with a life of its own to lead. New techniques are brought into operation from time to time, only to be discarded as 'better' ones are developed. The female flies are housed in test tubes and isolated from each other: they oviposit on cotton wool plugs in the absence of any larval food, and are induced (or compelled) to have several blood meals. As a 'temporary expedient' they are denied the opportunity of mating. With every successive modification of original technique (each a 'temporary expedient', no doubt) a higher proportion of the flies survive for the desired period, and under these conditions, the flagellates thrive and multiply. Pharynx infections become more frequent and the first buccal cavity infection is announced in November 1925.

Still another modification is introduced, *viz*, rigid control (at $28^{\circ}\text{C.} \pm 1$) of the temperature at which the flies are compelled to live. The efficiency of the latest technique becomes firmly established by May 1926. The Commission is now ready to carry out transmission experiments on human volunteers.

Throughout this period not one of the modifications of the original technique can be claimed to simulate conditions necessary for the normal life of any insect, not even the rigid control of temperature on which such great stress is laid. On the contrary, the devices used for prolonging life are laboratory 'tricks of the trade' which normally have no counterpart in nature.

Notwithstanding this perfect technique the transmission experiments on human volunteers are a complete failure. Large numbers of infected flies are used and enormous numbers of flagellates introduced into the human body. The flagellates refuse to 'do their stuff': for some reason or other they are 'non-infective'.

The Commission now closes down, February 1931, after having been continuously at work in the field since March 1924.

Then suddenly, in 1940, Smith, Halder and Ahmed re-open the question with the announcement of still another technique for rearing sandflies and follow this announcement with a series of papers showing how easy it is to infect

hamsters, and even mice, if this new technique be adopted. What was this new technique? Nothing but the substitution of raisin juice for human blood after the first blood feed.

To Smith must be given the credit for this brain-wave. From a study of his paper (Smith *et al.*, 1940) his reasoning would appear to have been something like this: 'We have tried all sorts of devices for prolonging the life of the flies, most, if not all, of them being unnatural. But one thing has been forgotten. The flies are almost certainly blood-feeders in nature, so let us give them plant juices instead. It worked! Experiments with glucose, honey, bananas and melons were unsuccessful, apples gave promising results, but raisins were just "what the doctor ordered".'

In due course, Swaminath, Shortt and Anderson (1942) proved that Smith was right. All the human volunteers became infected.

It would appear that the change of diet from blood to raisin juice not only altered the 'constitution' of the fly so that the flagellates pululated with speed and vigour but in some mysterious way caused the latter to acquire a high 'virulence'. As a result of this dramatic success we are now asked to believe that *P. argentipes* feeds on plant juices in nature, although there is not a shred of evidence to support this view.

To summarize.—The claim that the conditions under which these laboratory flies were bred and reared were similar in all essentials to those obtaining in nature cannot be sustained. On the contrary they would appear to have been devised solely with the object of encouraging the flagellate to multiply and develop and were quite unsuited to the normal life of the fly. To maintain that absence of larval food, unvarying temperature conditions and a diet which prevents the development of the ovaries are the lot of the sandfly, in nature, is unreasonable if not absurd.

Epidemiological factors

In our article (Malone and Brooks, 1944) we claimed that 'the age incidence, sex incidence and communal nature of the disease, together with other epidemiological observations . . . cannot be reconciled with the theory of transmission by a biting insect'.

The writer makes only a feeble attempt to reply to our arguments. On the question of age incidence 'he is not prepared to argue'; with regard to sex and race incidence he finds the evidence 'too indefinite and involved' so we need not discuss these points further. We repeat, however, that unbiased evidence proves that males are three times as commonly affected with kala-azar as females. Infants in India are very rarely affected. These observations are not what could reasonably be expected if kala-azar were transmitted by a house-dwelling insect. In addition, Indian Christians, Anglo-Indians and Mohammedans are far more

Note.—'Anterior development' here implies forward development towards the mouth parts of the insect taking place to such an extent that it might be reasonably presumed that the insect bite is possibly infective. In referring to our original text in which we stated that the anterior development, as we have seen only, takes place when the life of the fly is artificially prolonged'. Shortt left out the inverted commas in which we had placed the words 'anterior development', thus robbing them of special significance; he then declared that our words were 'a simple mis-statement of fact'.

prone to the disease than Hindus and the explanation that Hindus are protected by cattle can no longer be maintained.

Shortt, however, objects to certain other arguments of ours :—

1. To our statement 'it is generally assumed that the distribution of kala-azar coincides with that of *P. argentipes* in India' he replies : 'The present writer is not aware by whom this assumption is made . . .'

We would refer him to the following authorities :—

(a) Knowles, Napier and Smith (1926). 'It had been pointed out to the senior writer by Major J. A. Sinton, V.C., I.M.S., that the known distribution of the sandfly *Phlebotomus argentipes* in India appeared to coincide* with that of kala-azar'.

(b) In the same article ' . . . in view of Major Sinton's observation with regard to the apparent identity* of the geographical distribution of *P. argentipes* and kala-azar in India . . .'

(c) Sinton (1925). 'As a result of this investigation it was found that there was a close relationship* between the recorded areas of distribution of *Phlebotomus argentipes* and that of kala-azar'.

(d) Christophers (1926) ' . . . as pointed out by Sinton (1925) the distribution in India coincides very closely* with that of *P. argentipes*'.

(e) Shortt et al. (1928). 'In 1922, Major J. A. Sinton, V.C., I.M.S., in a private communication to Lieut.-Colonel R. Knowles pointed out that the known distribution of *P. argentipes* in India corresponded closely* with that of kala-azar'.

The 'close relationship', 'apparent identity' and 'coincides very closely' are now whittled down to the following recent pronouncement by Shortt (1946). 'Although the actual record appears to be lost, there is no doubt that in 1922 Sinton, in a private communication to Knowles, pointed out that there appeared to be some correlation* between the distribution of kala-azar in India and that of *Phlebotomus argentipes*'.

Further argument on this point may now be left to the sophists.

2. In our article we remarked that it was difficult to understand why kala-azar is not endemic in Ceylon in spite of the fact that the islands almost linking Ceylon to the east coast of India are heavily infected with kala-azar and *P. argentipes* is present in Ceylon. Shortt replies that this 'is sufficiently explained by the fact that kala-azar is practically non-existent in these areas' (Bombay and Ceylon) and goes on to say : 'The same argument might have been used in the case of Assam before that province had cases of kala-azar imported . . .'. The argument is weak and the statement that kala-azar is practically non-existent in Ceylon

is quite misleading. Infected coolies have been imported into Ceylon year after year yet the disease has never spread to the indigenous population, while in Assam, village after village was readily infected by one or more infected persons. Since there is no evidence to show that *P. argentipes* are less numerous or less ready to bite human beings, or less addicted to raisin juice in Ceylon than in Assam, the writer must seek for some other explanation.

The comparison between malaria in Great Britain and kala-azar in Ceylon, which Shortt next introduces, is equally fallacious. Social, economic, environmental and hygienic conditions are entirely different in the two countries and there is no endemic centre of malaria near to Great Britain corresponding to the kala-azar-infected islands between India and Ceylon. Moreover, the fact noted by Shortt that the introduction of cases of malaria into Great Britain after the 1914-18 war, was followed by sporadic outbreaks of the disease, while the introduction year after year of kala-azar cases from India to Ceylon has no such effect would suggest that the anophelines in Great Britain are efficient carriers of malaria while *P. argentipes* in Ceylon are not.

3. The real issue, however, is not whether kala-azar is absent in the presence of *P. argentipes* but whether true indigenous cases are to be found in the absence of the sandfly. If this can be established the case against the sandfly must be dismissed.

We mentioned two indigenous cases occurring at Sanawar Military School in the Simla Hills (5,760 feet above sea-level) which occurred at a time when *P. argentipes* had not been found there, even though sandflies had been carefully looked for and 'several thousand specimens of this genus have been examined during the last seven years from areas within a few miles of Sanawar' (Sinton, 1927). In his paper Savage (1927) says : 'Neither of these boys can be traced to have ever visited any of the known endemic areas and hence they cannot be considered as imported infections'. 'That infection had occurred in Sanawar appears to me undoubted . . .'. Since Savage was medical officer of the school and already had under his care a case of kala-azar imported into the school from Madras, we must presume that he investigated the history of these unique cases very thoroughly before deciding that they were indigenous. There was no question at the time of these cases not being indigenous. Savage who was not an opponent of the sandfly theory notes :—

'*P. major* is the only sandfly that has been identified' and says in the concluding sentence of his paper : 'The object of this article is to draw attention to the possibility of *P. major* being a carrier of kala-azar in India, and to a hill station being an infective focus, with different regional conditions from the present known endemic areas'.

* Our italics.

The Editor's footnote to this article is illuminating: '(Note: It has been shown by the workers in China that *Leishmania donovani* will develop in the mid-gut of *Phlebotomus major*—Editor, *Indian Medical Gazette*)'. The editor not only accepts the view that the cases were indigenous, but endeavours, by subtle suggestion, to incriminate *P. major* in the absence of *P. argentipes*.

About six months later, Sinton (1927) in a letter to the Editor, *Indian Medical Gazette*, records that in a collection of *Phlebotomus* from Sanawar village given to him by Captain P. J. Barraud, F.E.S., F.Z.S., there were several specimens of *P. argentipes*. He mentions this as an illustration of the extremely localized nature of the distribution of the different species of *Phlebotomus* in an area.

At the meeting of the Far Eastern Association of Tropical Medicine (December 1927), in reply to Dr. U. N. Brahmachari's reference to kala-azar in Sanawar, Colonel Knowles said: 'Major Sinton has informed me that they have now found *P. argentipes* there. Here we have a most important and interesting finding, you find a patch of *argentipes* infection at a high altitude, and with it you find an isolated crop of kala-azar cases, presumably following after the importation of an infected person'.

Here again there is full acceptance of the view that the cases were truly indigenous, but now it is *argentipes* that is incriminated. In their enthusiasm for *argentipes* the exponents of the sandfly theory have overlooked two points mentioned by Sinton: (1) The flies were caught in Sanawar village (where no cases had occurred), two miles away from the school (where the cases had occurred but no *argentipes* had been found). (2) The distribution of the different species of *Phlebotomus*, in an area, is extremely localized.

We are now told by Shortt: 'The remarks on a few cases occurring in Sanawar in the Himalayas hardly call for an answer, because the facts about them were never sufficiently cleared up, and it is most probable that the cases did not acquire their disease locally, but actually came to Sanawar already infected in another part of India'.

There would appear to be no reason (and the writer has given none) for accepting, at this late date, a bare denial that the Sanawar cases were truly indigenous.

We suggested that George Town, Madras, provided another example of the presence of kala-azar, in a particular area, in the absence of *P. argentipes*. Kala-azar has been endemic in George Town for a long time, certainly before 1903. Patton who worked in Madras for several years failed to find *P. argentipes* in George Town up to 1922, *P. minutus* being the only species found. In 1926 during a flying visit of a fortnight Barraud finds *argentipes* in the majority of houses in the same area searched by Patton. We suggested that *P. argentipes*

might have been introduced into George Town between 1922 and 1926. Shortt replies: 'This sudden extension of the range of *P. argentipes* is not explained by them!' It would appear from the note of exclamation that he considers our suggestion to be ridiculous. The economic entomologist would not think so, and many examples of just such a phenomenon have been recorded. Indeed Napier (1926) argues, in support of the sandfly transmission theory, that the introduction of the transmitting agent was the determining factor in the introduction of kala-azar into the Assam valley. An argument that is considered reasonable enough when it supports the sandfly theory is ridiculed when it opposes that theory.

Again, by this easy dismissal of our suggestion, the writer is placed on the horns of a dilemma. For, if our explanation is incorrect, either Patton who failed to find *P. argentipes* when they were present was careless or incompetent, or Barraud who found them when they were not there was mistaken or dishonest. We have assumed (and rightly so) that both of these eminent workers were competent, careful and honest and we have accepted their findings as being correct. On this assumption we consider our suggestion that *P. argentipes* had been introduced into George Town between 1922 and 1926 to be a reasonable one.

Although these two examples do not afford proof that indigenous cases of kala-azar occur in areas where *P. argentipes* is absent, yet they have considerable value as the negative observations of two experts in the field of entomological research.

To summarize:—

1. The age, sex and race incidence of kala-azar cannot be reconciled with the sandfly theory of transmission; the writer has made little or no attempt to refute this statement.

2. There is evidence to suggest that indigenous cases of kala-azar may occur in areas where *P. argentipes* are absent.

Other possible methods of transmission

It is admitted that on a *priori* ground, the biologists have reason to suspect that kala-azar is transmitted by an insect vector, and it has been proved that, under certain laboratory conditions, *P. argentipes* can be an efficient vector. We maintain, however, for reasons previously given that this does not prove that they are the actual vector *in nature*.

That was the main object of our article. We, however, suggested that not only should the habits and behaviour of the sandfly, in nature, be thoroughly investigated, but the old-fashioned idea of transmission through personal contact should be further explored.

We quoted the observation of Rogers (1914), Korke (1913) and Michael (1926) in support of the view that close contact is a probable method of infection. Shortt's reply is that *P. argentipes* was common in the areas investi-

gated by those writers and 'that there is every chance of its becoming infected from the case or cases with which people are in contact, and so passing on the infection to the latter'. This possibility is admitted but the observation made by Korke that the disease was almost entirely confined to Anglo-Indians in the streets occupied equally with other communities and the careful house-to-house investigation of Michael showing the distribution of the cases in order of their occurrence suggested that close personal contact was much more likely to be the method by which the disease was transmitted.

Greig and Christophers (1926) stated: 'The way in which cases of kala-azar occur in infected families, one case following another in slow succession, is very characteristic of carrier transmission as seen in enteric, where infection is through the soiling of food, etc., more especially from the urine'. 'There is no inherent improbability, therefore, in so far as general epidemiological facts are concerned, in the view that kala-azar might be transmitted by contact infection'.

Later the Kala-azar Commission, with Shortt as Director, proved that *L. donovani* were excreted in the urine and faeces of kala-azar cases; that the forms of *L. donovani* found both in the human body and in test-tube cultures can infect susceptible animals when administered by the oral route; and that infected animals housed in proximity to uninfected animals were able to infect the latter (see Report of the Kala-azar Commission, 1932, p. 65). It is a pity that this promising line of research was not pursued much further.

L. donovani has been found frequently in the skin. 'All levels of the skin below the epidermis contained leishmania-filled cells collected in large masses about the sweat glands and arterioles and scattered diffusely through the corium' (Manson-Bahr, 1935). In the Soudan and in China this phenomenon is seen in ordinary visceral kala-azar; in India the parasite is frequently found in dermal lesions.

Napier (1935) considers that a dermal infection is a constant sequel to a visceral infection, whether the patient has received treatment or not and argues that the dissemination of the parasites to their dermal foci takes place during the visceral phase. *L. donovani* have been recovered from the skin when blood cultures were negative in clinically cured cases and in cases where dermal lesions are hardly apparent or not apparent at all.

From our point of view the presence of *L. donovani* in the skin suggests that the disease may possibly be transmitted directly from skin to skin, through abrasions, for example, and that an intermediary insect vector may be an unnecessary complication.

Shortt states: 'The fact that the parasites in the blood are usually not free but within the elements of the reticulo-endothelial system, is only natural, since that is their natural habitat'.

This explanation may be correct especially in view of the fact that the parasite appears to multiply in lymphocytes, but it should also be borne in mind that such parasites are admittedly phagocytosed and it is possible that such phagocytosed parasites are *not* in their 'natural habitat'.

Unless and until it is proved that wild flies and flies bred and reared under laboratory conditions will act in the same way, further argument would appear to be fruitless.

In conclusion, we ask our readers to study the main arguments against the sandfly transmission theory under the heading 'Bionomics of *P. argentipes*' and 'Epidemiological Factors' and to decide for themselves whether the protagonists of the theory have proved their case or not. It is apparent that sufficient attention has not been paid to the study of *P. argentipes* in nature, and the mass of epidemiological evidence which casts grave doubt on the correctness of the sandfly transmission theory of kala-azar has been ignored or denied.

In self-defence

We must protest against the suggestion made by Colonel Shortt at the meeting of the Royal Society of Tropical Medicine and Hygiene (17th May, 1945) that criticism of a scientific investigation should be confined to those who have worked in that particular field of research. It is the privilege, and indeed the duty, of anyone to offer his criticism provided it is fair and logical.

We regret that Colonel Shortt's reply to our article has offended in both these respects.

The introductory remarks in his paper clearly reveal the temper with which he has approached the problem. He opens on a facetious note which calls for no comment from us, then makes much play of two mis-statements in the opening section of our article which he ascribes, incorrectly and without justification, to 'the casual manner of their reading of the works of others'. He is, however, not generous enough to point out that neither of these mis-statements has the slightest bearing on the arguments put forward by us.

In the main part of his paper he accuses us of lack of knowledge or of ignorance, either without justification or in the face of evidence to the contrary presented in our article. We are also accused of drawing inferences which we did not draw.

Some of our arguments have been misunderstood or misinterpreted; others have been avoided.

In quoting from our article portions of a sentence have been omitted and sentences removed from their context so as to give an erroneous impression of our meaning or intention.

In cases where the onus of proof lies upon the protagonists of the sandfly transmission theory he has attempted to shift it to their critics.

In short, his paper does not provide the kind of reply expected of a scientist of high repute but rather that of a pleader who has a weak case which he is compelled to defend.

In this rejoinder we have endeavoured to deal, fairly and without rancour, with his objections to our contention. We have tried to avoid as far as possible controversy on points which we consider to be of secondary importance or have only an indirect bearing upon our main arguments.

We apologize if in treading on this holy ground sacred to the pundits we have inadvertently trodden on the tails of their coats. Although the accuracy of some of our statements may be questioned our main arguments cannot be ignored, and we hope in the near future to see in this journal, or in any other of equal repute, an advertisement to this effect:—

Wanted

A team of young and enthusiastic research workers to study the life history of *Phlebotomus argentipes* in nature. Special training in tropical diseases is not essential.

Medical News

NOTIFICATION OF THE BOMBAY MEDICAL COUNCIL

No. G/16 of 1947

THE names and addresses of the following candidates who have been duly nominated for election as members of the Bombay Medical Council under the Bombay Medical Act, 1912 (Bombay Act VI of 1912) as amended by Bombay Acts No. III of 1916, No. IV of 1918, No. XII of 1929 and No. III of 1945, are published in accordance with the Rules and Regulations of this Council:—

No. G. 16/1 of 1947

Notice to the Electorate constituted by sub-section (c) and sub-section (d), respectively, of section 2(2) of the Bombay Medical Act, VI of 1912, as amended by Bombay Acts No. IX of 1912, Nos. III and IV of 1946, No. IV of 1918, No. XII of 1929 and No. III of 1945.

Whereas in section 3(1) of the Bombay Medical Act, VI of 1912, it is laid down that the members of the Medical Council shall hold office for a term of five years, and whereas the term of office of the existing six elected members of the Bombay Medical Council expires on the seventeenth day of September 1947.

Now, therefore, in accordance with rule 11 of the Rules and Regulations of the Bombay Medical Council, approved by the Governor of Bombay in Council and published in Bombay Government Notification (General Department), No. 6773, dated the 22nd September, 1913 (as amended from time to time) the two Electorates mentioned below are required to elect members in the room of the six elected members whose term of office expires on the seventeenth day of September 1947.

Under sub-section (c) of section 2(2) of the Bombay Medical Act, VI of 1912, as amended by Bombay Acts Nos. III and IV of 1916, No. IV of 1918, No. XII of 1929 and No. III of 1945, four members are to be elected by Doctors, Bachelors and Licentiates of Medicine, and Masters, Bachelors and Licentiates of Surgery of the University of Bombay, who are registered under this Act.

Under sub-section (d) of section 2(2) of the Act, two members are to be elected by the medical practitioners who are registered under the Act and who are not Graduates in Medicine or Surgery or Licentiates in Medicine or Licentiates in Medicine and Surgery of the University of Bombay.

Persons nominated as candidates under section 2(2) (c) of the Act

No.	Name	Qualification	Address
1	Dr. Vasant Keshav Chitnis ..	M.B.B.S. (Bom.), D.O. (Bom.)	Honorary Ophthalmic Surgeon, Sir C. J. Ophthalmic Hospital, and Professor of Ophthalmology, Grant Medical College, Byculla, Bombay.
2	Dr. Rustamji Nassarvanji Cooper	M.B.B.S. (Bom.); M.S. (Lond.), F.R.C.S. (Lond.).	Marshal Lodge, Cumballa Hill, Bombay.
3	Dr. Mahadev Dattatraya Joshi	M.B.B.S. (Bom.), D.M.R.E. (Camb.), F.C.P.S. (Bom.).	Dr. Bhajekar Street, Bombay Nursing Home, Sandhurst Road, Bombay 4.
4	Dr. Chamanlal Maneklal Mehta	M.B.B.S. (Bom.), F.R.F.P.S. (Glas.).	2nd Dadiseth Road, Babulnath, Bombay 7.
5	Dr. Gopal Krishnayya Mulki ..	M.B.B.S. (Bom.), M.R.C.S. (Eng.), L.R.C.P. (Lond.), F.R.C.S. (Eng.).	C/o S. K. Mulki, Esqr., Allahabad Bank, Bombay.
6	Dr. Rangarao Damodar Naik ..	M.B.B.S. (Bom.)	Lady Jamshedji Road, near P. O., Dadar, Bombay 14.
7	Dr. Motibhai Desaiabhai Patel ..	M.B.B.S. (Bom.), L.R.C.P. (Lond.), F.R.C.S. (Eng.).	Vadilal Sarabhai General Hospital, Ellis Bridge, Ahmedabad.
8	Dr. Nilkanth Lakshman Ranade	M.B.B.S. (Bom.)	330, Sadashiv Peth, Poona City.

Persons nominated as candidates under section 2(2) (d) of the Act

No.	Name	Qualification	Address
1	Dr. Dattatraya Mahadev Akut	L.C.P.S. (Bom.)	204, Rasta Peth, Poona City.
2	Dr. Keshavlal Jivanram Bhatt	L.C.P.S. (Bom.)	235, Ghosiram's Pole, Ahmedabad.
3	Dr. Udyavar Bhadya Narayanrao	L.C.P.S. (Bom.)	1, Damodar Mansions, Opera House, Tram Terminus, Girgaum, Bombay 4.
4	Dr. Vaman Dinkar Sathaye ..	L.C.P.S. (Bom.)	502, Narayan Peth, Poona City.

SWADESHI MILLS ESTATE,
New Queen's Road, Post No. 4,
Bombay, the 5th August, 1947.

B. M. SIDHAYE,
Registrar, Bombay Medical Council
and Returning Officer.

Any person who is qualified for election to the Council under section 2(2) of the Act may be nominated as a candidate for election either under sub-section (c) or under sub-section (d) of section 2(2) of the Act.

Candidates qualified for election must be proposed and seconded by persons qualified as electors, i.e. by persons borne on the Bombay Medical Register on the 30th June, 1947, no elector shall propose or second the nomination of more persons than are required to fill up the vacancies. If more nominations than are required to fill up the vacancies are subscribed by the same elector, all nominations subscribed by him shall be void.

Every candidate for election shall sign the nomination paper declaring that he is willing to serve on the Council, if elected, failing which the nomination paper shall be invalid.

Every proposal for nomination must be in writing and must be dated and signed by the proposer and seconder who must be qualified as elector, and must be sent by post or otherwise so as to reach the Returning Officer at the office of the Bombay Medical Council, Swadeshi Mills Estate, next to Roxy Cinema, New Queen's Road, Bombay No. 4, not later than 5 p.m. on Monday, the 4th August, 1947.

Forms of nomination will be supplied to any elector on application to the Returning Officer.

Monday, the 25th August, 1947, has been fixed as the date for the issue of voting papers to electors. Voting papers should be despatched so as to reach the Returning Officer not later than 12 noon on Monday, the 15th September, 1947.

Monday, the 15th September, 1947 (2 p.m.), has been fixed as the date for the counting of votes at the office of the Bombay Medical Council, Swadeshi Mills Estate, next to Roxy Cinema, New Queen's Road, Bombay No. 4.

Only those whose names stand on the Electoral Roll prepared in accordance with rule 12(1) of the Rules and Regulations of the Bombay Medical Council, will be entitled to vote. The Electoral Roll can be seen

at the office of the Council on any weekday during office hours.

B. M. SIDHAYE,
Registrar,
Bombay Medical Council,
and Returning Officer.

SWADESHI MILLS ESTATE,
NEXT TO ROXY CINEMA,
NEW QUEEN'S ROAD,
BOMBAY 4.
21st July, 1947.

EDINBURGH AS POST-GRADUATE CENTRE

(Abstracted from the *Lancet*, i, 14th June, 1947, p. 838)

THE Edinburgh Post-Graduate Board for Medicine is at present conducting short refresher courses and four long courses per year—two in internal medicine and two in general surgery. Applications for enrolment far exceed vacancies, and selection of candidates according to qualifications and experience is made.

Edinburgh was always known as a gathering-point for overseas students, and the present post-graduate classes contain an ever-increasing number of graduates from South Africa, Canada, India, and other parts of the world. Undoubtedly, some Dominion visitors particularly those from Australia and New Zealand, who formerly came in large numbers, are deterred by the fear that they may not find accommodation. The board helps, where it can, by passing on the addresses of recommended lodgings and private hotels; but their number is often insufficient, and the authorities are seeking to buy a building capable of housing 80 to 100 students.

MOTOR-CARS IN FRANCE: THE FLIGHT OF PARISIAN DOCTORS

(Abstracted from the *Medical Journal of Australia*, Vol. I, 7th June, 1947, p. 709)

MEDICAL practitioners who are having difficulty in securing suitable motor-cars for their daily requirements

in practice will be interested in a report published in *The Times* of 8th March, 1947. It is stated that more than eight hundred doctors of the Paris region marched through the heart of the city in protest at what they considered were insufficient transport facilities. They carried placards asking for more motor-cars, and on the placards were such slogans as: 'Cars exported to get dollars'. 'How many dollars is the life of a Frenchman worth?' A letter was handed to the Minister for National Economy stating that two thousand Parisian doctors were without motor-cars, that others had only 'wheezing' vehicles, and only sixty-three motor-cars, had been distributed between seven thousand doctors since the liberation. The Minister replied that three hundred new motor-cars should be distributed amongst doctors every three months and that the quota would soon be increased to four hundred.

CHANG SHAN IN THE TREATMENT OF MALARIA

(Abstracted from the *Journal of Tropical Medicine and Hygiene*, Vol. 50, No. 4, April 1947, p. 75)

Chang Shan, an indigenous Chinese drug, has been found effective in the treatment of benign and malignant tertian malaria.

ANTI-TUBERCULOSIS CHALLENGE SHIELD

The Tuberculosis Association of India awards the Subhwardy Memorial Anti-Tuberculosis Challenge Shield annually to the organization or institution which has the best record of effective anti-tuberculosis work done within that year.

Anti-tuberculosis work for the purpose of this competition includes, among other activities, house-visiting and contact examinations, propaganda, anti-tuberculosis legislation, surveys, insurance, medical examination of school children, housing schemes, care and after-care committees and such other details which the Association prescribes.

Competition for the Shield is open to Corporations, Municipalities, affiliated Tuberculosis Associations, District or Local and other recognized bodies doing anti-tuberculosis work.

The following three items are reproduced from Release No. MNL/114 offered by the Public Relations Officer, Australian High Commissioner's Office New Delhi:

Australian State Plan for Dental Health

The State Government in Victoria (Australia) will spend Rs. 10,00,000 on the extension of school dental services. The aim of the plan is to expand the service gradually until it reaches every school child.

State Minister for Health, Mr. Barry, said the plan provided for: appointment of many more qualified dentists; establishment of permanent clinics in the larger provincial cities, with one or more mobile units to visit surrounding country schools; temporary clinics in the larger schools along railway routes, small schools to be served by additional dental vans operating over wide areas in every part of the State.

In Victorian State and denominational primary schools there are 250,000 children. The Government's plan aims at offering the facilities of the dental service to every school-age child, with one treatment per child annually as the minimum.

Until the fulfilment of the plan, to be considered by Cabinet, it is estimated that a staff of 70 dental officers would be required to operate 15 mobile dental vans, and give service at the headquarters and other clinics.

Degree of the extension of the service planned is indicated in that during the year ended 30th June, 1947, approximately 18,500 treatments were given to 13,500 school children in Victoria at the State dental clinic and mobile vans.

Segregation of T.B. Patients Halves T.B. Infection Risk Among Australian Nurses

Skin tests of 2,700 Sydney nurses carried out by a Sydney physician, Dr. Douglas Anderson, M.D., M.R.C.P., F.R.A.P., over five years show that the risk of infection was more than twice as great when tuberculosis sufferers were cared for in the general medical wards than if they were cared for in special wards.

The tests were carried out on the nurses of three of Sydney's largest hospitals. At the first and third hospitals there were 27 and 26 infections respectively for every 100 nurses per year of observation, while at the second hospital there were only 11 infections for every 100 nurses per year.

At the first and third hospitals patients with pulmonary tuberculosis were nursed in the general wards, while at the second hospital patients known or found to have tuberculosis were placed in special wards and cared for by a general staff. Even then the nurses' risk of infection (11 per cent) was three times as great as that among young women in the general Australian population (where infections have been shown to be 3.5 per cent).

However, infection with tubercle bacilli very rarely leads to lesions of the lung in Australia; lesions developed in only 15 of 2,300 nurses tested during their five years' professional training.

Dr. Anderson used an Australian technique which enabled him to carry out each skin test with only a single injection of the purified protein derivative of tuberculin ('Tubercilin P.P.D.'), thus avoiding a sore arm in the case of those who react very sensitively. The new Australian technique which has been found to be satisfactory as well as time-saving, is to inject a strong solution with enough tuberculin to get a reaction from all persons tested, but in a very small bulk of one-fortieth of a cubic centimetre.

Delicate Operation Restores Hearing

Medical circles in Australia are showing great interest in a series of delicate fenestration operations for the restoration of hearing performed by surgeons who studied the technique under the noted American Surgeon, Dr. Julius Lempert.

The operation, known as the Lempert fenestration method, consists of making an opening, or window, to the inner ear to permit the entry of sound waves, and is suitable only for hereditary deafness produced by abnormal growth of bone over the natural opening. This type of deafness is known as otosclerosis.

Exhaustive clinical and audiometric tests are made before the operation, and the family history of the patient is studied, before it is known whether the case can be treated successfully.

Fenestration technique restores hearing by giving the patient a new freely vibrating window to receive sound impulses. The new opening is made by drilling through the mastoid antrum, to the lateral semi-circular canal, enlarging the window by burring, and then drawing a tongue of skin over it from the external canal.

An Australian surgeon performing the operation in Melbourne, recently returned from the United States where he studied ear operations in Boston and New York. He worked for some time under Dr. Julius Lempert.

He states that 54 per cent of fenestration operations in the United States are successful. Early results from operation in Australia are promising. Almost complete hearing has been restored by each operation, but a conclusive result cannot be guaranteed until it is certain that the bone-forming processes will not begin over again and cover over the newly-made window. In that case, a further operation is necessary.

Public Health Section

THE CARE OF PREMATURE INFANTS

By W. C. HANSZE, L.M.P. (Madras)

Group Medical Officer, Mulhalkelle, Halgranoya, Ceylon

ALL infants born before full term, that is, before the fortieth week of pregnancy, may be considered as premature. The diagnosis of prematurity depends not only on the period of gestation when the child is born but also on its weight at birth. Children born before the thirty-sixth week of gestation and weighing less than $4\frac{1}{2}$ pounds are to be treated as premature and require more elaborate care than those born at term. The most important points to be noted in their management and care are :—

1. The baby must be kept in a warm room on a well-padded cot. In cold climate or cold weather hot-water bottles should be placed on each side under the side pillows and slightly away. It is most important to conserve the heat of the body. The temperature should be taken with a thermometer in the fold of the groin morning and evening. When incubators are available the temperature in the incubator should maintain a uniform level of about 78°F ., and there should be efficient ventilation within the incubator. In dealing with these it is essential to maintain the body temperature at 98° to 99°F . To ensure this the temperature must be recorded every 4 hours.

2. The infant should be clothed warmly but not so as to impede the free movements or interfere with the process of respiration or to the extent of perspiration. No tight-fitting clothing about the chest or abdomen should be encouraged. The body should be gently rubbed with sesame or olive oil slightly warmed morning and evening and wrapped in cotton-wool. In cold countries the feet and hands should also be protected by flannel gloves or wrapped in small quantities of cotton-wool. Pieces of cotton-wool should be used as napkins. The child should be disturbed as little as possible, yet frequent changes of the napkins are necessary, so that the solid pieces of cotton may not be in contact with the tender skin. The infant should be carefully guarded from infections. A premature infant should not be bathed until it has gained in weight after which it may be sponged quickly with warm water twice or thrice a week, and it should be weighed in the same clothing from day to day. When good nursing can be obtained, the premature infant does much better at home than in hospital, because of the added risk of infection in institution. All nurses should wear efficient masks and sterilized gowns when handling an infant like this.

3. All feeding utensils should be boiled. There should be as few visitors as possible and they should not handle the infant. Any slight infection, particularly the common cold, may rapidly prove fatal to the premature infant. The child's skin, particularly about the buttocks and navel, must be inspected daily for signs of sepsis, and should be kept dry with sterile dusting powder.

4. Writer's favourite treatment is with oestroform tablets (British Drug Houses preparation). Take one tablet (1,000 I.U.) of oestroform, dissolve it in 2 drachms of water, give one drachm in the morning and one drachm in the evening until the child is progressing satisfactorily. Twenty premature infants responded very well with this line of treatment.

Now comes another important item, *viz*, feeding according to Steen's recommendation giving breast milk diluted with equal quantity of boiled water for the first few days. Commence with half to one ounce of breast milk per pound of body weight daily or one to two drachms per feed. By the fourth day try giving two ounces of breast milk per pound of body weight per day and by the tenth day or so the ideal of three ounces per pound of body weight may be reached. Some babies cannot be advanced so rapidly and it may be 20 days before the ideal is attained. Writer tried this method with excellent results.

In-feeding do not exhaust the child by making it suck for long. If it is weak or is not obtaining sufficient breast milk employ manual expression and give the milk off a spoon to the baby while it is in the cot. Two-hourly feeds may be required. Writer recommends an excellent premature feeder made by Messrs. John Bell and Croyden, 50 Wigmore Street, London, W.1, and termed the Belcroy Feeder. This is most useful when there is difficulty in getting the infant to suck. At all times the hole in the teat should be made extremely easy. Glaxo Company, Allen and Hanbury's and other firms manufacture a special bottle and small teats for premature infants. When the breast milk is not available, writer recommends *Hæmolac*, a dried milk powder to which iron has been added prepared by the Cow and Gate Company, as an excellent food at this juncture, or 5 or 10 drops of a solution of ferri et ammon cit. (one grain to one drachm) may be added to each feed. The most important point to be borne in mind is that the premature infant is born without that reserve of iron stored in the liver which carries the full-term child through the period of lactation. Anæmia is therefore liable to appear about the end of the third month and must be corrected either by giving a small quantity of

Marmite Soup daily or by the administration of some easily absorbed form of iron. The premature is specially liable to develop rickets. As soon as the diet is fully established Emulsion of Cod-liver Oil with Metagen (P. D. & Company preparation) is a valuable nutrient tonic which has been found excellent in many cases by the writer. Some form of vitamins such as Ostelin, Radiostoleum, Adexolin and the like contain concentrated vitamin D, and a few drops a day is needed. Directions are sent with vial. Fresh fruit juice, preferably orange juice one teaspoonful a day, should also be given to provide the anti-scorbutic factor.

The Indian Medical Gazette Fifty Years Ago

THE HEALTH OF PRISONERS

(Reprinted from the *Indian Medical Gazette*, Vol. 32, September 1897, p. 344)

THE sick and death-rate amongst prisoners in Indian jails is a subject which frequently gives rise to much adverse criticism amongst a certain section of politicians and jail reformers at home, who, through ignorance of the conditions under which Indian prisoners live previous to, and their physique on admission into jail, etc., are ever ready to attribute excessive sickness and mortality to some defect or other in the jail itself or its administration. The vital statistics of the present day (excepting epidemic years) compare favourably with those of past years—a result which, in our opinion, must be ascribed for the most part to the increased attention given to sanitary regulations in the matter of accommodation, ventilation, water-supply, food,

clothing, the disposal of the excreta of both the healthy and sick, and the precautionary measures adopted to check the dissemination of infectious and contagious epidemic diseases. We would not for a moment say that the sanitary arrangements are perfect, but that they have undergone considerable improvement within recent years is undeniable. Despite all this, however, there remain factors conducing to unhealthiness, over which superintendents and medical officers can exercise no control whatever, viz the widespread prevalence of malaria and its concomitants, the habits and customs of prisoners before admission, the extreme variation of climatic conditions at different seasons of the year and even at different hours of the same day—diseases acquired during transfer, from one jail to another, and the effect of the change from a home life, however humble, to that of a solitary existence, which is perhaps more felt even by the most despicable native criminal than by prisoners in English jails.

Moreover, the native of India, as a rule, dislikes hard labour intensely, and, while in jail, practises all kinds of deceptions and malingerings with a view to being sent to hospital, and may be safely entrusted by some device or other to raise his temperature to hyperpyrexia at a moment's notice, or by the consumption of unhusked rice, green fruit, raw vegetables or other objectionable material produce such an attack of dysentery or diarrhœa as will almost defy the best attempts of the medical officer to effect a cure.

When everything is said and done, we venture to believe that the death-rate in Indian jails might be still further reduced by the employment of a well-trained nursing establishment, and, if the suggestion is at all practicable, it seems desirable that something should be done in this direction. The provision of wards for prisoners admitted into jails in a moribund condition and a hospital to be specially set apart for those suffering from incurable diseases is, we think, deserving of consideration. The medical officer, who hopes to suppress *in toto* factors conducing to unhealthiness amongst Indian prisoners, has his task before him.

LONDON LETTER

(Reprinted from *The Indian Medical Gazette*, Vol. 32, September 1897, p. 347)

BERI-BERI has broken out again in the Richmond Lunatic Asylum, near Dublin. One hundred and twenty-four cases have occurred since the beginning of June—90 female patients, 3 nurses and 30 male patients. The disease first made its appearance in the institution in the year 1894, and has continued to prevail at intervals up to the present time. The authorities are greatly exercised regarding it. The question of origin is shrouded in dense darkness, and will

probably never be solved. The asylum is damp and overcrowded; but this does not account for the appearance of so specific a malady. Once introduced, the conditions—feeble resistance, humidity and crowding—are eminently favourable to its maintenance and spread; but it is impossible to admit the spontaneous generation of a tropical disease in an institution situated in a temperate climate. Cases of beri-beri are continually being imported into our large seaports, but no extension of the disease has ever been known to take place in London, Liverpool, or Glasgow. It is true that personal communication plays a very small part in its dissemination, and that it is a localized distemper flourishing in unhealthy places inhabited by dense communities, such as crowded jails and stuffy forecastles. Still these facts do not render much assistance in explaining its entry into this asylum. The alternate prevalence and latency which have been observed are of seasonal causation, warmth being evidently a necessary element of vitality and propagation of the micro-organism to which the disease is due. The precise microbe which causes beri-beri is a matter of some uncertainty. Different observers have described several different forms; but there is good reason for the belief that the micro-organism of Pekelharing and Winkler is the veritable *causa causans* of the disease. At any rate there can be no manner of doubt that very radical measures are necessary in order to extirpate the malady from the Richmond Asylum. The abandonment of the building and the erection of a new one on a drier site would probably be the best course; but the temporary removal of the patients and reconstruction of the asylum on a larger scale and with all possible sanitary improvements seems to be imperative.

The bacteriology of yellow fever is exciting some interest at present. Not long ago the announcement was made that the specific bacillus of the disease had been discovered by Dr. Sanarelli. Now a competitor has appeared in the field, and Dr. W. Hanelberg of Rio de Janeiro has described an organism differing from that of Sanarelli in many important particulars, which he considers to be the true cause of yellow fever. Which of the two will finally establish its claim will depend on further investigation. But these sudden upsets are very disconcerting. To expect finality in the vital sciences is, of course, out of the question; but of all vital sciences bacteriology seems to be the most unsettled. A position is laid down one day which presents every appearance of stability; but the storms and floods of criticism and fresh discovery beat against it next day, and show by its quick demolition that it was founded on the sand. Witness the uncertainty that prevails regarding the causation of cholera and typhoid fever, and the shifts to which the supporters of Koch's vibrio and Eberth's bacillus are put to square their hypothesis with inconvenient facts. Nothing seemed more secure a short time ago

than the truth and practical value of Vidal's sero-diagnosis of typhoids, and yet we have Kanthack declaring in the last issue of the *British Medical Journal* that he obtained a typical positive reaction with serum from a patient in whose body after death no lesion of enteric was found. It is hard to be in a state of continual provisional belief in regard to these matters; but it would be still more painful to inhabit a fool's paradise and find the palatial building every now and then tumbling down and leaving one stunned, startled and houseless. After all, doubting has its advantages and pleasures and after fully discounting the uncertainties of bacteriology there still remains a grand residue of established facts for which we are bound to be very grateful.

I had the pleasure of attending the prize-giving at Netley on Friday last. The function was presided over by Major-General Sir William Butler, K.C.B., commanding the South-Eastern (Dover) Division, who discharged the duty with grace and ability. The mess gave a dinner to Dr. Cayley on the 29th on the occasion of his vacating the chair of Military Medicine. The competition for admission into the medical services is going on at present. I hear that there are 37 applicants for 18 vacancies in the Indian Medical Service and 27 competitors (!) for 30 declared vacancies in the Army Medical Staff. The latter service does not gain in popularity notwithstanding the redress of several grievances, and it is becoming apparent that the service must be rendered more attractive if it is to retain its prestige and efficiency.

I am sorry to observe that the Calcutta Medical Society is in a state of dormancy. It has now attained an age which ought to be a guarantee of permanence and there should in Calcutta be no lack of men and materials, nor of ability and ardour to secure its perpetuity and success. It only wants a very moderate measure of interest and industry to make a thing of this sort work. It possesses the great advantage of being associated in practice if not in constitution with a great hospital and school, the officers of which must always have something under observation worth drawing attention to; and the *alumni*—the past students and officials of both—cannot but derive pleasure and profit from revisiting their *alma mater*, renewing their acquaintance with their former haunts and studying the changes in doctrine and method which new years and men are constantly producing. I cannot get myself to believe that there is such a lack of desire to teach and learn and of devotion to the most interesting of all professions and occupations in Calcutta as to permit an institution, which has done good work in the past, to die of inanition. I do hope, therefore, that with the commencement of a new session the Calcutta Medical Society will have started a new era of activity and usefulness.

The 5th August, 1897.

Current Topics, Etc.

Survival of Variola Virus in Dried Exudate and Crusts from Smallpox Patients

(Abstracted from the *Lancet*, i, 26th April, 1947, p. 550)

THE chorio-allantoic membranes of developing hens' eggs which are susceptible to infection with variola virus have been used to detect the presence of virus in vesicle fluid and crusts from smallpox patients.

By this means virus was found to survive in diluted vesicle fluid dried on glass slides for 35 days when exposed to daylight and for 84 days when kept in the dark at room temperature.

Virus was recovered from different samples of crusts kept at room temperature for several months and from one specimen kept thus for over a year.

In crusts exposed to daylight virus survived as well as in crusts kept in the dark.

A Death from Pethidine

(From the *British Medical Journal*, i, 19th April, 1947, p. 548)

THE Westminster coroner inquired on 28th March into a death due to an overdose of pethidine (the hydrochloride of the ethyl ester of 1-methyl 4-phenyl-piperidine 4-carboxylic acid). A clerk of 44 was found unconscious in a Paddington hotel and died soon afterwards. Four bottles of $\frac{1}{2}$ -gr. (50 mg.) tablets, from which 54 tablets were missing, were found in his room. Dr. G. Roche Lynch said in evidence that this was the first fatal case of pethidine poisoning he had met. The drug has an action similar to that of morphine. As it was discovered to produce addiction in some cases it was placed under the Dangerous Drugs Act in February last in England.

Red Cells as a Dressing

(Abstracted from the *Lancet*, i, 3rd May, 1947, p. 604)

LITTLE would probably have been heard of the therapeutic value of powdered human blood cells if they had not been a by-product of plasma extraction. The Mayo Clinic workers have been applying the powdered cells to ulcers of the extremities associated with vascular disorders including thrombo-angiitis obliterans and venous insufficiency from varicose veins. The rationale of this treatment is still obscure; it is suggested that the favourable response observed may depend on partial desiccation, some healing factor in the cells or nutrition supplied by the crust or it may be that the crust encourages healing merely because it is protective and entirely non-irritating. The powder is kept in sterile glass containers and is either applied with a sterile swab or spatula or dusted on from a sprinkler and then loosely covered with a dry sterile dressing. It is reapplied daily after careful removal of the crusts. The results were satisfactory in 24 out of 46 cases and there were only 3 that entirely failed to respond. A considerable number of the patients had previously proved resistant to other forms of treatment. Measures to improve the local circulation must of course not be neglected.

Distribution of Penicillin in the Eye after Subconjunctival Injection

(Abstracted from the *Lancet*, i, 3rd May, 1947, p. 594)

THE distribution of penicillin in the various tissues and fluids of the eye has been studied in rabbits after

subconjunctival injection of 50,000 units of pure sodium penicillin dissolved in 0.5 c.cm. of normal saline into one eye.

In the injected eye high levels were found in all the tissues of the eye except the lens and the vitreous; within three to six hours these levels had fallen to below an adequate bacteriostatic level.

A similar distribution was found in the opposite (uninjected) eye but with lower levels. The penicillin content of most of the tissues of the opposite eye exceeded that of the blood.

The highly purified penicillin now obtainable is non-irritant to the eye and can thus be safely given in large doses by subconjunctival injection with the production of very high local concentrations in the ocular tissues. Its use may prove a valuable advance in the treatment of infections of the eye by penicillin-sensitive organisms.

The following five items are reprinted from a Surgical Newsletter No. W-451, dated May 1947, prepared by the American Medical Association:—

Anatomic Data regarding the Surgical Treatment of Angina Pectoris

SACCOMANNO and his associates point out that the surgical procedures devised for relief of pain of cardiac origin have involved extensive interruption of preganglionic or postganglionic nerve fibres. All attempts, apparently, have been made without complete evidence of the exact origin of the preganglionic and postganglionic sympathetic neurons or of the exact course taken by the afferent pain fibres of spinal ganglion origin which accompany these sympathetic nerve complexes. It is the object of this investigation to determine the exact origin of the preganglionic cardiac accelerator fibres. This was done with the aid of a series of experimental procedures involving direct stimulation of the nerve trunks and roots as they issue from the thoracic spinal cord. Dogs were used as the experimental animals.

Summarizing their observations the authors say that in dogs from which a length of spinal cord had been removed, stimulation of the isolated spinal nerves was observed to produce cardiac acceleration and a rise in systemic blood pressure when the second through the sixth thoracic spinal nerves were stimulated. No change in heart rate or blood pressure was observed when the eighth cervical or first thoracic spinal nerves were stimulated, indicating that these segments do not convey cardiac efferent fibres.

The effect in pulse rate was greatest in the second and third thoracic nerves, with diminishing effect in the fourth and fifth and only very slight effect below the fifth thoracic nerve. The effect on systemic blood pressure was more or less constant from the second thoracic down as far as the seventh thoracic nerve.

Attention is called to the implications of this information as the anatomic basis for a more scientific surgical treatment of angina pectoris. By means of surgical removal or alcohol injection of the second, third and fourth thoracic sympathetic ganglions on the affected side only, a complete alleviation of anginal pain and a reduction of coronary vasospasm should result. This single surgical procedure does not completely interrupt the pathways of sympathetic effector impulses to the head and upper extremity, since the first thoracic segment which conveys fibres to these areas, but which does not convey cardiac afferent or efferent fibres, remains intact.

(Saccomanno, G., Utterback, R. A., and Klemme. R. M.: *Ann. Surg.*, 126, 49, January 1947.)

The vitamin intake in Febrile conditions

The restricted diet associated with febrile illnesses involves a reduced intake of vitamins and minerals at a time when the heightened metabolic rate calls for an increase.

A multiple vitamin and mineral supplement (Complevite) is an essential addition to all such diets.

Supplying the full physiological requirements in this way offers the greatest likelihood of shortening the illness.

COMPLEVITE

The adult daily dose provides:—Vitamin A 4,000 i.u., vitamin B, 200 i.u., vitamin C 400 i.u., vitamin D 300 i.u., calcium 153 mg., iron 68 mg., trace minerals 3 p.p.m.

Further particulars concerning Complevite and Fertitol from Martin & Harris Ltd., Mercantile Building, Lall Bazar, Calcutta.

Products of Vitamins Limited, London, England.

A treatment of TENO-SYNOVITIS by means of Elastoplast

CASE HISTORY

On the 16th January a bricklayer, aged 31, complained of pain at the back of the wrist. It was particularly noticeable when grasping.

A radiograph revealed nothing abnormal, but clinically there was synovial crepitation in the extensors.

Treatment—Fingers immobilised by postero-anterior strips of Elastoplast binding them over a roller bandage. Another turn of Elastoplast bandage strapped the wrist.

On the 23rd January there was still slight pain and

Elastoplast was re-applied to the hand and wrist only.

By the 30th January there were no symptoms.

The patient returned to work after 14 days, but the Elastoplast wrist strapping was retained for a further week.

The details and illustration above are of an actual case. T. J. Smith & Nephew, Ltd., are privileged to publish this instance, typical of many in which their products have been used with success in the belief that such authentic records will be of general interest.

Elastoplast elastic adhesive bandages are available in widths of 2", 2½", 3" and 4" × 5/6 yds. long when stretched. Also 2" wide × 1½ yds. (stretched). Elastoplast, Elastocrepe, Jelonet and Gypsona are products of T. J. Smith & Nephew, Ltd., Hull, England.

FERTIOL (VITAMIN E and all the other factors of Wheat Germ Oil)

Used in the treatment of habitual abortion, sterility of dietary origin and certain neuro-muscular degenerations.

Fertitol is a highly active natural and stable source of vitamin E and of the other factors of wheat germ oil. Each 5 minim capsule is standardised to contain 3 mg. α -tocopherol.

Wheat germ oil has given better clinical results¹ in some trials and shown properties additional to those of pure α -tocopherol.

WOMEN AND THE CLIMACTERIC

For thousands of women who undertake heavy tasks through employment—and even in the home—muscular pains, backache and headache are the inevitable results of too-prolonged efforts.

This applies particularly to those subject to dysmenorrhoea and those approaching middle age and the climacteric.

Veganin gives most satisfactory results in such conditions since it is a synergistic association of codeine, acetylsalicylic acid and phenacetin, producing rapid and prolonged relief without ill effects. Veganin is not advertised to the public.

A NEW ANTISEPTIC FLAVAZOLE

FLAVAZOLE is an equimolecular chemical combination of Proflavine base and Sulphathiazole synthesised in the laboratories of Boots Pure Drug Co., Ltd., Nottingham, England. Clinical results have shown Flavazole to be most effective against a wide range of bacteria when applied as a dusting powder diluted with a sulphonamide or when used as a neutral saturated solution (1:2,500).

Flavazole is available as follows:—

FLAVAZOLE

Bottle of 25 gm.

COMPOUND FLAVAZOLE POWDER

(Sterilized)

(Flavazole 2% Sulphathiazole 98%)

Carton containing 12 sifter packets
of 5 gm.

Bottle of 15 gm.

A Method for the Arrest of Spreading Gas Gangrene by Oxygen Injection

HINTON says that the treatment of gas gangrene by injection of oxygen into the tissue, *per se* or through the use of hydrogen peroxide and the direct application of oxygen to the wound, is not new, but the use of measured amounts under controlled pressure and with aseptic technique, continued over a long period of time, was not possible under past methods.

The machine described here and the method of its use was brought to the author's attention when he had a case of gas gangrene of the forearm, secondary to compound fracture of both bones which in spite of gas serum before and after primary operation, secondary operation, amputation, penicillin and sulfa therapy, extended to the thorax.

By fortunate circumstance, a demonstrator of an oxinjector, who had supervised the injection of oxygen in 12 cases prior to this one, was in the hospital. Two patients with a similar condition of the upper extremity were recently seen, one involving the torso, making 15 cases in all, without mortality and in some instances without loss of limb.

Surgical treatment is to be used on all gas gangrene cases plus penicillin, etc., and oxygen injection is designed simply for the purpose of walling off the infected areas, preventing further spread and then aiding in the retrogression of the lesions. The addition of it to other treatment has in at least two of the cases been the difference between life and death.

The author describes the instrument and its operation and gives a detailed report of the aforementioned case, in which the oxygen was inserted through seven portals and eventually oxygen emphysema extended almost to the pubes. Only a small amount of oxygen rose above the clavicle and this produced difficulty in swallowing and talking. In less than 72 hours all discoloration had disappeared.

The author stresses that the described procedure is a controlled and scientific method of blocking the spread of gas bacillus infection of extremities and trunk, and is an adjuvant to proper surgery in gas gangrene.

(Hinton, D.: *Am. J. Surg.*, 73, 228, February 1947.)

Effect of Oestrogenic Hormone on Advanced Carcinoma of the Female Breast

THE favourable results obtained by some English investigators with oestrogenic hormones in women with advanced carcinoma induced Herrmann and his associates to try this procedure. They selected 17 patients, 13 of whom had primary inoperable cancer, which had not been treated before. Two patients had recurrent lesions. Of the remaining two patients one had a carcinomatous ulcer in the mastectomy scar and the other had recurrent nodules in the skin of the thoracic wall. A biopsy specimen which was positive for cancer was obtained in every case. These 17 patients were treated exclusively with a synthetic oestrogenic hormone (ethinyl oestradiol) administered orally. The dose of ethinyl oestradiol varied from 0.15 to 0.7 mg. daily.

There was a favourable response in seven, or 40 per cent of the patients, five with superficial lesions of the soft parts and two with pulmonary metastases. The favourable response occurred predominantly in women over 60 years. The dosages employed induced uterine bleeding, sometimes severe, in over 50 per cent of the patients. Vaginal smears were studied in six patients, all of whom showed a well developed oestrus reaction.

The authors stress that their experiences with the oestrogenic hormone treatment does not differ greatly from that reported by British authors in about 100 cases. An important point of agreement is that the favourable results are obtained predominantly in women above the age of 60. The results suggest that oestrogens have a decidedly deleterious effect on women

in the younger age group. This appeared to be most striking in a 40-year-old patient who was menstruating regularly. When first seen in the clinic her general condition was good despite the mass in the right breast and right axilla. Soon after the institution of the oestrogen therapy her condition deteriorated. Within three months she was bedridden, and she died about one month later.

(Herrmann, J. B., Adair, F. E., and Woodard Helen, Q.: *Arch. Surg.*, 54, 1-9, January 1947.)

Surgical Treatment of Bronchiectasis

THIS report is based on observations of the treatment of 390 patients with bronchiectasis during a three-year period. There were 220 consecutive lobectomies with only one death. One hundred and eighty-four lobectomies were performed for bronchiectasis, 20 for pulmonary cysts, 11 for chronic pulmonary suppuration, three for bronchial adenomas associated with suppuration, and two for basilar tuberculosis. Post-operative broncho-pleural fistulae and empyemata occurred in only 20 cases, an incidence of 9.7 per cent. Pulmonary function as determined by broncho-spirometric studies in a small group of patients pre- and post-operatively demonstrated that the oxygen consumption and ventilation within several months post-operatively were only slightly below normal values and in most cases either essentially the same or improved over pre-operative levels.

In no instance was the pulmonary function following an uneventful lobectomy significantly impaired, and it was shown that two to three months post-operatively pulmonary function on the operated side was within normal limits. The principal conclusion is that permanent cure in bronchiectasis can be attained only by pulmonary resection.

(Kay, Earle, B., and Meade, Richard, H., Jr., and Hughes, Felix, A., Jr.: *Surgical Treatment of Bronchiectasis. Ann. Int. Med.*, 26, 1, January 1947.)

Intermittent External Biliary Drainage for Relief of Pruritus in Certain Chronic Disorders of the Liver

VARCO points out that in certain chronic disorders of either the hepatic parenchyma or intrahepatic biliary system intractable itching is an unpleasant feature. These patients frequently suffer miserably from this unrelenting annoyance, and their generalized cutaneous excoriations attest to the transient or incomplete relief obtained through the therapy customarily employed. Dihydroergotamine, injected intramuscularly, will often control the pruritus for a short while, but is invariably followed with a return of the desire to scratch.

If the abnormal retention of bile salts is associated with or is the cause of the pruritus, then relief from the itching may be anticipated if it is possible to reduce this concentration in the circulation. A rational therapeutic approach; therefore, appeared to be the development of some method for the reduction of the serum bile salt level. Since from the total quantity of bile salts secreted each 24 hours, about 90 per cent is reabsorbed from the intestinal tract, recirculated through the liver, and then re-eliminated in the bile, a pre-enteric deviation of bile should theoretically eventually reduce the serum bile salt level. These conjectures have been translated into surgical procedures applied to clinical material, and it has been found that intermittent external biliary drainage suffices to attain and maintain prompt and virtually complete relief from this type of pruritus. Seven operations have been performed on six patients without fatality.

Small quantities of bile salts have been given orally upon three occasions to patients in this series during the time each had an external biliary fistula. Pruritus promptly returned and then disappeared with maintenance of the external biliary drainage.

In no instance has it proved necessary to develop a complete or even high-grade deviation of the bile in order to provide satisfactory surcease from the itching. Circuiting the bile to the outside for short intervals daily has sufficed to keep these persons comfortable. In all patients, chronic hepatic disease, either hepatitis or cirrhosis, has been pre-operative diagnosis, and this has been confirmed by the pathologic report of liver biopsies secured during the surgical procedure. It should be emphasized that pruritus associated with acute hepatitis is so frequently a self-limited disease, that any surgical procedure for its relief would seem unwarranted.

(Varco, R. L.: *Surgery*, 21, 43-45, January 1947.)

The following six items are reproduced from Medical Newsletter No. M-449, dated May 1947, prepared by the American Medical Association:—

Immersion Hypothermia

WAYBURN says that during the year 1944 approximately 150 men who had been immersed in waters of the North Sea were seen by medical officers at an Air Forces fighter station in England. A majority of the men showed no immediate effects from immersion other than temporary fatigue. Among 192 men picked up from various kinds of aircraft 163 survived. Of the 29 who died all but three were dead at the time of rescue. Those patients who suffered from such immersion on return to long combat flying missions are reported in detail.

Four of the patients had transient electrocardiographic abnormalities. One had abnormalities of blood chemistry. It was concluded that immersion hypothermia is a progressive clinical syndrome which may follow immersion in cold water. It is related to experimental hypothermia and to clinical shock. The clinical picture is the resultant of the coldness of the water, the length of the exposure, the emotional factors affecting the patient before and during exposure and the specific response of the person to cold. The chief effects are those on (a) the cardiovascular system (among the transient conditions observed were auricular fibrillation and flutter, ventricular extrasystoles, slight prolongation on the P-R interval and falling arterial blood pressure, with narrowing of the pulse pressure), (b) the nervous system (partial to complete loss of consciousness and irrational behaviour were observed) and (c) the blood (haemoconcentrations and notable hyperglycemia were found in one case).

Treatment consists in rapid restoration of normal body temperature by external heat, minimal activity, administration of warm fluids by mouth and, in severe conditions, use of blood plasma. No drugs were used in this series. Use of epinephrine is contra-indicated.

(Wayburn, Edgar: Immersion Hypothermia. *Arch. Int. Med.*, 79, 77, January 1947.)

Treatment of Lymphoblastic Leukemia with Crude Myelokentric Acid

EIGHT cases of blastic lymphoid leukemia have been treated with myelokentric acid in crude form, because hypothetically in blastic lymphoid leukemia there is a deficiency of this material. The crude myelokentric acid was used because it was more easily obtained than partially purified material. Purification of biologically active materials by methods of extraction and precipitation necessarily results in a considerable loss of material. Thirteen partial remissions occurred following the administration of crude myelokentric acid. Seven of the eight patients have died, and five necropsies were performed.

The necropsy material adds further weight to the belief that the remissions were induced by the myelokentric acid in that in all five necropsies there was a definite alteration in the histologic morphology as contrasted with the findings in the necropsies of the

controls. The authors concluded that it seems inadvisable to treat a large number of patients with this material because it is crude, it is relatively unavailable, and no standard dose has yet been devised.

(Miller, F. R., Herbut, P. A., and Jones, H. W.: The Treatment of Lymphoblastic Leukemia with Crude Myelokentric Acid. *Blood, The Journal of Hematology*, 11, 15, January 1947.)

Pathologic Changes from Streptomycin

THE authors employed 42 monkeys, 11 dogs, 350 rats, 100 mice, 10 chickens, and 154 guinea-pigs in their experiments aimed at studying the pathologic effects resulting from the administration of streptomycin. The parenteral administration of highly purified as well as average streptomycin samples resulted in fatty metamorphosis of the liver in monkeys and dogs.

Large doses of streptomycin concentrates produced small foci of necrosis in the livers of a few dogs. Fatty metamorphosis was observed less often in the kidneys of monkeys and dogs treated with streptomycin. Albuminous detritus appeared in the subcapsular spaces and the tubules of the kidney in some of the monkeys. Hyaline and granular casts, epithelial cells and occasionally blood cells were seen in the sediment of the centrifuged urine of dogs receiving large doses of streptomycin concentrates. Focal tubular necrosis occurred in the kidneys of one dog. The fatty change observed in the liver and the kidney was found to be reversible. It was not followed by permanent pathologic damage.

Complete studies of the blood of monkeys, dogs and rats treated by injection of streptomycin revealed as the only significant change slight normocytic anemia, which disappeared on cessation of dosage. Prolonged administration of streptomycin concentrates of average purity (230 to 310 micrograms of streptomycin base per milligram of solids) resulted in neurotoxic effects in dogs, manifested by disturbances of equilibrium and possibly of auditory acuity. Spontaneous recovery occurred in one animal.

No lesions which could explain these effects were evident in the limited material studied. Streptomycin samples of higher potency (640 to 710 micrograms of streptomycin base per milligram of solids) did not produce neurotoxic symptoms in dogs.

(Mushett, Charles W., and Martland, Harrison, S.: Pathologic Changes Resulting from the Administration of Streptomycin. *Arch. Path.*, 42, 619, December 1946.)

Urethane of B-Methyl Choline and Gastric Motility

THE subcutaneous administration of urethane of B-methyl choline in a post-vagotomy patient, who had marked gastric retention, led to a restoration of gastric peristalsis and motility, and relieved him of his epigastric distress, anorexia and nausea. Subsequently its oral and sublingual administration had a similar effect. A placebo was not equally effective. In another vagotomized patient, the parenteral administration of the drug induced sufficient gastric tonus and peristalsis, as well as pyloric relaxation to permit duodenal intubation, a procedure which was readily accomplished prior to vagotomy, but which was impossible during an 80-day post-vagotomy period without the use of the drug. The clinical effects of the drug in both of these patients were demonstrated roentgenologically and by means of balloon-kymographic records.

(Machella, Thomas F., et al.: The Restoration of Gastric Motility by Urethane of B-Methyl Choline after Section of the Vagus Nerves for Peptic Ulcer. *Gastroenterology*, 8, 36, January 1947.)

Fatal Coronary Artery Disease in Young Men

THE purpose of this report is to present a study of nine cases of fatal coronary artery disease in young men taken from the records of a single Army hospital.

These nine cases comprised 3.2 per cent of all autopsies, a total of 280, performed on men between 18 and 40 years of age. The nine cases comprised 7.4 per cent of all autopsies, a total of 121, performed on men between the ages of 18 and 40 years who died of natural causes. Very few of these nine young men gave evidence of having had symptoms of coronary disease before the fatal episode. Death was sudden and unheralded.

Most of the nine young men who died of coronary artery disease were of average or below average height. Cardiac weight did not reflect the seriousness of the cardiac condition. Slight to moderate enlargement of the liver may have been related to the cardiac disease. Evidence of old myocardial injury is frequent; evidence of fresh infarction is rare in young men dying of coronary artery disease.

(Poe, William D.: Fatal Coronary Artery Disease in Young Men. *Am. Heart J.*, **33**, 76, January 1947.)

Lancefield Groups of Beta-Hæmolytic Streptococci in Respiratory Infections

THIS investigation is part of a series on respiratory diseases conducted by The Commission on Acute Respiratory Diseases of the United States Army Preventive Medicine Service. In a large Army camp only 6 per cent of the patients with respiratory infections admitted to the hospital from an organization of new recruits were due to streptococcal infections. Bacteriologic and immunologic studies demonstrated that 90 per cent of the infections were due to group A, 4 per cent to group C and 3 per cent to group G. Clinical and epidemiologic evidence suggested that a few patients had infections due to groups B and F.

The illnesses produced by the various groups of beta-hæmolytic streptococci were similar. Streptolysin O antibodies were demonstrated in serum specimens obtained from patients harbouring organisms of groups A, C and G. Antifibrinolysin developed in patients with infections due to group A and group C streptococci. The titre of antifibrinolysin in the serum specimens taken during the acute and convalescent phases from patients with infections due to groups C and G was identical when measured with fibrinolysin prepared from organisms of groups A, C and G.

(The Commission on Acute Respiratory Diseases: The Role of Lancefield Groups of Beta-Hæmolytic Streptococci in Respiratory Infections. *New England J. Med.*, **236**, 157, 30th January, 1947.)

Maintaining Nitrogen Balance with Amino Acids

By M. L. SOENKE *et al.*

(Abstracted from the *American Practitioner*, Vol. I, January 1947, p. 276)

It was demonstrated that parenamine, acid hydrolysed casein fortified with 1 per cent di-tryptophane, is an adequate source of amino acids for the maintenance of nitrogen equilibrium. Two normal adults and two hospital patients were studied.

In the case of the two normal adults the average daily nitrogen retention was 0.61 gm. and 0.68 gm. when the nitrogen intake was 191 mg. and 211 mg. per kilogram of body weight, respectively. The caloric intake was 50 calories per kilogram for both cases.

A patient with ulcerative colitis was maintained in equilibrium by oral administration of parenamine. The average daily retention of nitrogen was 1.94 gm. when the daily nitrogen intake contained 273 mg. nitrogen and 58 calories per kilogram of body weight.

With adequate caloric intake, a diabetic woman was maintained in positive balance by oral and parenteral administration of parenamine.

These studies emphasize the necessity of an adequate caloric intake in order to maintain a positive nitrogen balance when amino acids are the sole source of nitrogen.

No attempt was made to use a basal level of either nitrogen or calories.

The Ageing Population

(From the *Medical Officer*, Vol. 77, 19th April, 1947. p. 160)

IN his final report as medical officer of health for Glossop after 27 years' service, Dr. E. H. M. Miligan draws attention to the ageing of the population. He writes: 'In 1921 the percentage of Glossop's population who were 65 years or over was 5.5, in 1931 the percentage had risen to 8.7. In 1921 the number of males was 492 and females 639; total 1,131. In 1931 the number of males was 644, females 1,103; total 1,747. If the census of 1941 had been taken, there is little doubt the percentage of old people would have been increased further. In the ten years ending 1912, 29.5 per cent of all deaths were those of persons of 65 years of age and over; for the 10 years ending 1939 the percentage dying at 65 years or over has risen to 58 per cent—just about double.'

Reactions from Intravenous Glucose

(From the *Medical Press*, Vol. 216, 18th December, 1946, p. 454)

THE occurrence of a reaction following intravenous glucose therapy using so-called pyrogen-free solutions is explained by Seibert. Pyrogens are chemical substances which are elaborated by bacteria; the latter may grow even in distilled water. Many species of bacteria may produce these substances, but the most common types are those found in river water. The name is derived from the fact that the substances produce febrile reactions when injected parenterally. Pyrogens pass through most bacterial filters, and are not activated by the heat applied in autoclaving solutions or equipment for parenteral treatment.

In the preparation of equipment for parenteral therapy two steps must be observed: (1) the equipment must be thoroughly washed with pyrogen-free solutions, such as distilled water that has recently passed through a proper still; and (2) the apparatus must be autoclaved within a few hours (approximately six) to destroy any bacteria which may have been introduced since the cleansing.

If a solution of dextrose is employed which was manufactured commercially and tested for pyrogens, and reaction follows, then the pyrogenic substances must result from imperfect preparation of rubber tubing and other apparatus. In such a case the pyrogens could be washed out by allowing the first 100 to 200 c.c. of the dextrose solution to be discharged through the apparatus and discarded before the injection into the patient is begun. The occurrence of pyrogens in the equipment for parenteral treatment is a strong argument for entrusting the preparation of such materials to a few specially trained personnel in a hospital.

Reaction to Oils and Fats

(Abstracted from the *British Medical Journal*, *i*, 29th March, 1947, p. 420)

Oils and fats are often deliberately introduced for therapeutic purposes by no means always with harmful results. Penicillin and other drugs are to-day administered in wax and vegetable oils, and for radiographic purposes iodized poppy-seed oil is introduced into the bronchus, apparently without any ill result, although

the oil remains for many months in the bronchi. On the other hand, mineral oils injected subcutaneously cause severe reactions, as many beauty-seekers know to their cost. Lanoline injected into the peritoneum produces a foreign-body-reaction tumour within a few days. And there is no doubt that the inhalation of mineral oils may induce severe and sometimes fatal reactions in the lung—a condition usually described as lipoid pneumonia. Many oily medicaments for treating sinusitis are on the market, and their use is probably wide. They are bland, as the rather eighteenth-century terminology has it, and cause no cough reflex. The majority of recorded cases of lipoid pneumonia have been, however, in patients who were very young, very old, comatose, or with paralysis of the muscles of deglutition. Paterson discovered 8 cases in 813 necropsies at University College Hospital, London, a surprisingly large number in view of the small total number in the literature. R. E. Rewell contributes in this number a further case, which is in many ways unusual. The patient was a previously healthy young woman, and there was no history of administration of oily substances in any form. There are undoubtedly cells containing macrophages in the alveoli, and these contain fat. The nodules in the spleen and liver are also most exceptional in lipoid pneumonia. As the author says, however, the case is a pretty problem in differential diagnosis. Some pathologists might prefer to look upon the condition as granulomatous and the lipoid-containing cells as representing the non-specific reaction, commonly seen in the lung, to which we have referred.

Though vegetable oils are inert in the human organism, it is well to remember that animal fats even of homologous origin cause foreign-body reaction. Mineral oils, being emulsified, are exceedingly dangerous in the wrong place and especially in the lung.

Plasma Mepacrine Reconsidered

(Abstracted from the *British Medical Journal*, 24th May, 1947, p. 728)

SULPHONAMIDES are distributed approximately equally through most of the body fluids and tissues. Mepacrine behaves quite differently since it has a high affinity for protein and for certain types of cells. Most of the mepacrine is stored in the tissues and only a small proportion is found in the blood. The concentration in the skin is approximately 80 times that of the blood, in the muscle 50 times and in the liver 2,000 times. In the blood itself distribution is uneven. The concentration in the erythrocytes is up to twice that of the plasma and in the leucocytes over 200 times. The concentration in whole blood is approximately four times as great as that in the plasma. Finally of the mepacrine in the plasma 80 to 90 per cent is bound to plasma proteins and 10 to 20 per cent is dissolved in plasma water; presumably it is this last fraction which is in equilibrium with the mepacrine in the tissues. In view of this complex distribution there was much discussion during the war as to which concentration of mepacrine—in plasma, in blood, or in some other fluid—was the most important. On the authority of Shannon and his colleagues it was generally agreed that plasma mepacrine was the most reliable indication of the level of mepacrine in the other tissues of the body. A great deal of work was done on this assumption, for example, the extensive observations made on volunteers at Fort Knox, and all aspects of the dosage of mepacrine and of its suppressive and therapeutic actions against malaria were related to plasma mepacrine levels.

The whole basis of this work has now been questioned in a recent paper by Marshall and Dearborn, working in the laboratory which launched 'blood concentrations' into modern therapeutics. They studied the therapeutic action of mepacrine in the malaria produced in ducks by *Plasmodium lophurae*, the host-parasite combination which has been most widely used in recent

American laboratory work on malaria. Ducks maintained on a constant daily dosage of mepacrine showed marked variations in the plasma concentration of mepacrine, both between different ducks and in the same duck on different days. These variations are due mainly to variations in the distribution ratio between plasma and tissues, most of the compound being stored in the latter. (Although not mentioned by Marshall, much of this variation might well be due to changes in the level of ammonium ions, since even low concentrations greatly influence the distribution of mepacrine between cells and body fluids.) The concentrations of mepacrine in the tissues and in the erythrocytes were much less variable than those of the plasma. There was little or no correlation between plasma concentration and therapeutic effect, but there was good correlation between dosage and therapeutic effect. Although this work has still to be confirmed, and it remains to be shown that what happens in ducks also happens in man, this paper calls for reconsideration of the basic assumptions of investigations on mepacrine. It does not invalidate all studies of the concentrations of drugs in body fluids; it merely points out that in the case of mepacrine the plasma concentration is not such a reliable indicator as was previously believed.

In that case there might be much to be said for going back to the estimation of its concentration in whole blood, taking precautions to check the leucocyte count. The whole blood concentration is much easier to measure than the concentration in the plasma, it can be done by a simple, portable, and cheap instrument described by King and Gilchrist. However, mepacrine is rapidly becoming out of date.

Pemphigus and Allied Conditions

By M. MICHAEL

(Abstracted from the *Acta Medica Orientalia*, Vol. 6, March 1947, p. 106)

(1) THE description of hitherto unknown forms of pemphigus and pemphigus-like skin eruptions may necessitate a new classification of pemphigus and diseases related to it.

(2) Experimental studies of the past 15 years, to some extent, lend support to the hypothesis of their production by a transmissible virus, as far as pemphigus and Dühring's disease are concerned. Further investigation will be necessary to elucidate the metabolic changes of the skin in pemphigus.

(3) Sulpha drugs and penicillin have, as a general rule, proved to be of but transitory effect in pemphigus and pemphigus-like diseases and their influence is probably confined to an effect on secondary infection.

(4) Favourable results in the treatment of pemphigus have been reported by several authors for large doses of vitamin D, the effect of which has not yet been satisfactorily explained.

Tuberculosis Mortality in World War II

By E. R. LONG

(From the *American Review of Tuberculosis*, January 1947, as abstracted in the *Journal of the American Medical Association*, Vol. 134, 3rd May, 1947, p. 18)

COMBINED figures from the office of the Surgeon-General and the Veterans Administration, representing the tuberculosis mortality of the entire army group, including its discharged members, are now available. This group, consisting of about 4 million men in 1942 and increasing to more than 11 million in 1945, had an average tuberculosis mortality of less than 4 per hundred thousand per year in 1942. The mortality increased to about 6 per hundred thousand per year in 1943 and to 10 in 1944. A slight rise was again evident in 1945, the last period for which figures are available, when the average mortality for members of

the existing army and discharged men and women who had served in the Army from 1942 to 1945 increased to 12 per hundred thousand per year. During this time the gross mortality rate for males of corresponding age in the United States fluctuated slightly but remained fairly constant at about 52 per hundred thousand population per year. The phenomenon observed is of great epidemiologic importance. A group with a relatively low tuberculosis mortality rate at the start, but with a certain percentage of unrecognized cases in its midst, has shown a significant rise in its rate within a period of four years, at a time when the mortality rate of the population from which it was drawn has remained practically constant.

Streptomycin

(Abstracted from the *Pharmaceutical Journal*, Vol. 158, 22nd March, 1947, p. 182)

THE Council on Pharmacy and Chemistry of the American Medical Association have accepted streptomycin for admission to 'New and Non-official Remedies'. It may be prepared in the form of salts, including the hydrochloride and sulphate salts. It is not a pure product but is marketed as a sterile powder in airtight ampoules or vials, the activity in terms of milligrams or grammes of pure streptomycin base being declared on the label. Streptomycin and its salts are reasonably stable, but should be stored at a temperature not in excess of 15°C. Solutions of streptomycin are less stable than the dry powder and should always be kept in the refrigerator. Only freshly prepared solutions should be used parenterally.

Streptomycin is useful in the treatment of urinary tract infections due to streptomycin-sensitive gram-negative organisms. In the presence of obstruction, streptomycin is of only temporary benefit, and successful therapy depends on correction of the underlying anatomic condition. *Pasteurella tularensis* is highly susceptible to streptomycin, and this agent is the most effective treatment for tularemia at present available. Influenzal meningitis due to various haemophilus organisms has been successfully treated with streptomycin, as have infections in other parts of the body. Wound infections, bacteraemias and other infections due to streptomycin-susceptible organisms may be treated with this agent. Experience with streptomycin in undulant fever, bacillary dysentery and typhoid has been disappointing, and failure has been the rule. Until further work elucidates the place of streptomycin in these infections, its use cannot be recommended.

Although streptomycin shows promising results in the therapy of tuberculosis infections in guinea-pigs, the clinical experience in human infections has not been sufficiently large to delineate its precise rôle in the control of human tuberculosis. At best it does not appear to offer more than limited usefulness as an adjunct to other forms of therapy.

The antibiotic is capable of producing side reactions of varying severity. Certain lots have been found which produce a histamine-like reaction on parenteral administration with a fall of blood pressure and syncope. This is due to some accompanying toxic material, and its occurrence is now rare. The most serious toxic effect, states N.N.R., is its neurotoxic action on the eighth nerve, which may occur in about 10 per cent of patients treated with large doses (3 to 4 gm. daily) over periods of several weeks to months. On cessation of therapy, partial recovery of eighth nerve function is the rule, although this recovery is slow, and vestibular function appears to be permanently impaired although compensation occurs. Minor toxic effects include skin rashes, mild malaise, muscular aching and drug fever.

For intramuscular injection, the powder should be dissolved in sterile, pyrogen-free distilled water or isotonic solution of sodium chloride to give a concentration of from 100 to 200 mg. of streptomycin base

per mil. For subcutaneous injection, more dilute solutions are recommended. If the drug is administered by intravenous drip, 1 to 2 gm. dissolved in a litre of isotonic solution of sodium chloride may be administered at a rate of about 25 drops per minute. For intrathecal administration, 10 to 20 mg. per mil. in isotonic sodium chloride solution should be used. For topical application, solutions containing 25 to 50 mg. per mil. may be used. It is recommended that the dosage be governed by the susceptibility of the organism responsible for the infection. In severe fulminating infections, doses of 2 to 4 gm. daily may be necessary, given in divided doses parenterally, every three hours. In less severe infections, and with highly susceptible organisms, daily doses of from 1 to 2 gm. may be sufficient. Treatment should be continued for at least forty-eight to seventy-two hours after the temperature returns to normal and all signs of infection have disappeared. It is pointed out that sufficiently large doses should be given to inhibit or kill the infective organisms quickly, since the development of 'fastness' to streptomycin is common and may occur rapidly. Inadequate dosage predisposes to the development of resistant strains of the organisms.

American manufacturers supply the sulphate and hydrochloride in vials containing the equivalent in activity of 1 gm. of streptomycin base, except that one manufacturer supplies the equivalent of 0.375 gm. of base.

Psoriasis

By J. TAS

(Abstracted from the *Acta Medica Orientalia*, Vol. 6, March 1947, p. 79)

1. A review is made of 380 cases of psoriasis registered, during the years 1920-1946, at the Dermatological Out-patient Clinic and Hospital Department of the Hadassah University Hospital in Jerusalem, with the aim in view to ascertain the effect of a hot climate on psoriasis and its incidence in Jews. Further, the difference was studied between the incidence in the more or less pigmented Oriental and the fair-complexioned European Jews.

2. The relative frequency (among other skin diseases of patients visiting the Out-patient Department) was 0.56 per cent on an average (minimum 0.27 per cent, in 1921; maximum 1.30 per cent in 1925).

3. Psoriasis was seven times as frequent among European (Ashkenazic) Jews as among Oriental and Shephardic Jews. As the latter groups are more or less pigmented this may confirm the view that psoriasis occurs with lesser frequency in pigmented people. It should be noted that patients of Oriental extraction constitute about half of our patients in Jerusalem.

4. The low relative frequency of psoriasis in Palestine, as compared to 3 to 7 per cent in Europe where also lay the countries of origin of half of our Jerusalem and the vast majority of the Tel Aviv and Haifa patients, indicates that a number of immigrants from European countries have lost their psoriasis in Palestine. Equally it might be supposed that a number of children, born in Palestine but from European parents, have been spared.

5. The Palestinian climate does not prevent the outbreak of psoriasis.

Ninety out of 142 patients got their psoriasis with or after immigration. Moreover, the proportion of Palestinian-born patients is considerable (106 out of a total of 380).

6. It appears that the majority of the patients come from European countries or have European parentage.

7. No specific predilection for the Jewish race could be established.

8. The distribution of age was the following:

First quartile: males 20.2, females 12.5; median: males 24.5, females 19.4; third quartile: males 34.1, females 28.2.

9. No differences in the sexes could be established.
10. No definite influence of the seasons was found.
11. The clinical picture was in no way different from that encountered in European countries.

Uses and Abuses of the Male Sex Hormone

By W. O. THOMPSON

(Abstracted from the *Journal of the American Medical Association*, Vol. 132, 28th September, 1946, p. 185)

In order to carry out treatment with male sex hormone intelligently, it is necessary to bear in mind certain fundamental considerations. The use of this material represents substitution therapy, whereas the use of various gonadotropins represents stimulation therapy. The testis contains two structures which have different functions although their functions are related. The seminiferous tubules produce spermatozoa while the interstitial cells of Leydig produce male sex hormone.

The testis may fail because of some defect in the testis itself (primary hypogonadism) or because of lack of adequate stimulation, notably by the anterior lobe of the pituitary (secondary hypogonadism). There is a close relationship between the functions of the pituitary and the gonads. The follicle-stimulating material produced by the anterior lobe of the pituitary influences the function of the seminiferous tubules, while the luteinizing material stimulates the interstitial cells of the testis to produce male sex hormone. The hormone thus produced inhibits the pituitary so that a delicate balance exists.

Three types of gonadotropins are available; pituitary gonadotropin from the pituitary itself; equine gonadotropin from the serum of the pregnant mare, and chorionic gonadotropin from the urine of pregnant women. Pituitary and equine gonadotropin are theoretically desirable because they contain both follicles stimulating and luteinizing material, but in the male they are not particularly effective. Chorionic gonadotropin is decidedly effective for stimulation therapy. It is luteinizing material and stimulates the production of male sex hormone, but it has little effect on the seminiferous tubules.

Testosterone propionate is a potent therapeutic agent and its use is indicated chiefly in cases of primary hypogonadism in the male, namely, those in which the defect is in the testis itself. Its most important uses are in the treatment of the following conditions:—

Eunuchism.—The most clear-cut indication for the use of the male sex hormone is in patients showing loss of both testes.

If a person loses his testes at an early age, it is probably desirable to delay treatment with the male sex hormone until the tenth to the twelfth year of age; namely, the age at which puberty normally sets in. Treatment should then be given continuously for the rest of the patient's life. It is important not to delay treatment beyond this age, because the presence of hypogonadism during puberty results in skeletal disproportions, notably a short trunk and long extremities and a tendency to narrow shoulders and knock knees.

Primary eunuchoidism.—Eunuchoidism represents partial loss of testicular function, which may vary from a slight deficiency to almost complete loss of function. It is commonly but not necessarily associated with bilateral intra-abdominal cryptorchism. Eunuchoidism may be primary or secondary in type, the secondary variety being the result of lack of adequate stimulation by the anterior lobe of the pituitary. The two types can be differentiated chemically by determination of the follicle-stimulating hormone in the urine. When present in normal or increased amounts, it indicates that the stimulating mechanism in the pituitary is normal, but the testes are unable to respond. The two types may be differentiated therapeutically by the administration of chorionic gonadotropin in a dose of 500 to 1,000 international units three times a week by intramuscular injection. If the genitalia develop, it

may be assumed that the testes are capable of responding to stimulation and that the stimulating mechanism is inadequate.

Treatment of eunuchoidism is similar to that of eunuchism. In particular, it is important to begin treatment with male sex hormone at the age when puberty normally sets in. Since the condition is secondary in a considerable number of cases, it is probably best to use stimulation therapy with chorionic gonadotropin first and then resort to treatment with testosterone propionate if improvement fails to occur or does not become maximum.

In the treatment of the Fröhlich syndrome and undescended testes, the administration of testosterone propionate is not indicated unless both testes are in the abdomen and incapable of responding to stimulation. This state of affairs does not often obtain in the Fröhlich syndrome. The male sex hormone inhibits the normal testis and if given in large doses may cause azoospermia. It is therefore desirable to use stimulation therapy whenever the testis is capable of responding. Glandular treatment in the Fröhlich syndrome should be started at the age at which puberty normally sets in and continued until epiphyseal closure occurs.

The treatment of undescended testes should be started by the age of 3 years. Glandular therapy should be continued until moderate genital growth takes place. If descent has not occurred by this time, the testes should be brought into the scrotum by surgical intervention.

Pituitary dwarfism.—The male sex hormone is a potent stimulator of growth. In young boys receiving it for undescended testes and the Fröhlich syndrome, the growth in height is greatly accelerated and bone age increases rapidly. It is not a substitute for the growth factor of the pituitary or for the thyroid hormone, and without these substances the skeleton cannot attain normal height. Because of its growth-promoting properties, it is of some value in treating patients with pituitary dwarfism, in order to make sure that the growth associated with puberty takes place. There is no particularly effective commercial preparation of the growth factor of the pituitary available at the present time. The male sex hormone should be used in pituitary dwarfism only if both testes are in the abdominal cavity and incapable of responding to chorionic gonadotropin and this is not often the case in pituitary dwarfs. In almost all instances chorionic gonadotropin is the material of choice. Treatment with chorionic gonadotropin and male sex hormone should not be started in pituitary dwarfs until about the twelfth year. If it is started much earlier the bones may age rapidly and epiphyseal closure may set in before the skeleton has had an opportunity to derive the benefits of whatever growth might take place without the intervention of the male sex hormone.

Male climacteric.—In some men the production of male sex hormone falls off as they grow older. The decrease in production is sometimes great enough to produce definite symptoms, such as hot flushes, nervousness, irritability, palpitation, a decrease in mental acuity and physical stamina and other symptoms similar to those of the menopause in the woman. It is important not to conclude that every old man who is tired is suffering from the male climacteric. This diagnosis should be made only after the most careful search has been carried out to discover some other cause for the symptoms.

Impotence from glandular causes.—Impotence is a symptom and not a disease. It may, of course, be associated with hypogonadism in varying degrees, and it is then rather promptly relieved by the administration of male sex hormone or chorionic gonadotropin, whichever is indicated. It is often psychogenic or neurogenic in origin, and when this is the case glandular therapy is ineffective.

Cushing's syndrome.—The use of the male sex hormone has been recommended in Cushing's syndrome because it promotes the retention of nitrogen. It seems to be of some value in those patients who show a negative nitrogen balance.

Effective and Low Dosage Sulphonamide Therapy

with

IRGAFEN

(N,3, 4-Dimethylbenzoyl Sulphanilamide)

A well tolerated chemotherapeutic agent with definite action.
Total dosage 30-50% lower than that of other sulphonamides.

Indications :

Pneumonia, meningitis, B. coli infections, strepto- and staphylococcal infections, dysenteric enterocolitis, etc.

Tablets — Ampoules

J. R. GEIGY, S.A., BASLE
(SWITZERLAND)

For detailed literature please write to :

Amalgamated Chemicals and Dyestuffs Company Limited, P. O. Box 965, Bombay.

Convalescence

The building up of the system after illness, especially when anaemia and emaciation are present is definitely aided by the tonic — reconstructive action of Waterbury's Compound. This preparation presents products obtained by the enzymatic action of pancreatic ferments on cod liver oil, livers and spleens, malt extract and hypophosphites in a palatable form suited to the most fastidious palate. Waterbury's Compound improves the appetite and strengthens the digestive functions.

MARTIN & HARRIS Ltd.,
Mercantile Buildings, Lall Bazar, Calcutta.
Also at Bombay, Madras and Karachi

Made by Standard Laboratories Inc., New York and St. Louis, U.S.A.

WATERBURY'S COMPOUND

World-Wide Reputation

Allenburys Medicated Pastilles provide a selection of formulae appropriate to most medical affections of the mouth, nasopharynx, larynx, and trachea. They dissolve slowly in the mouth and ensure a thorough diffusion of the active ingredients over the buccal and pharyngeal mucous membrane. They obviate the inconveniences of dispensing and ensure medicaments of the highest quality, with accuracy and uniformity of dosage.

The best testimonial to the pre-eminence of Allenburys Pastilles is their world-wide popularity. This popularity, among physicians and the general public, is the result of unsparing efforts, during more than sixty years, to perfect every detail in the manufacture of the Pastilles.

In bottles containing approximately 3 ozs.

Addison's disease.—In many patients with Addison's disease, there is loss of all functions of the adrenal cortex, including the production of androgen. Such patients are rather listless and peopless even after adequate treatment with adrenal cortex extract or desoxycorticosterone acetate. In men the lack of adequate development of secondary sex characteristics is also observed. The beard is usually deficient, and there is usually little hair on the abdomen, chest, arms or legs, while in the axillary and pubic areas the hair is often scanty. The administration of testosterone propionate in men in addition to adrenal cortex extract or desoxycorticosterone produces more improvement than specific therapy alone.

Hypopituitarism with secondary hypogonadism in old men.—In patients with hypopituitarism, notably those with chromophobe adenomas, secondary hypogonadism is usually observed, and this is often associated with secondary hypothyroidism and occasionally with secondary hypofunction of the adrenal cortex. In men with this disorder chorionic gonadotropin or male sex hormone may be an important adjunct to therapy. In older men whose testicular function is waning it may be necessary to use male sex hormone rather than chorionic gonadotropin.

METHOD OF ADMINISTRATION

Three methods of administering the male sex hormone have been employed:—

1. Parenteral administration of testosterone propionate in oil. A dose of 25 mg. three times a week by intramuscular injection seems to produce a maximum effect in almost all cases.

2. Oral administration of methyltestosterone in a dose of 30 to 60 mg. daily.

3. The implantation of pellets.

Parenteral administration of testosterone propionate appears to be the method of choice. Oral administration of methyl testosterone produces most of the changes outlined above but is not as effective as parenteral administration. Pellets have not been used extensively, and there are not enough data on their use to warrant definite conclusions.

ABUSES OF THE MALE SEX HORMONE

The male sex hormone is of no value or is contraindicated in the following conditions: (1) sterility; (2) benign prostatic hypertrophy; (3) carcinoma of the prostate; (4) the Fröhlich syndrome with one or both testes in the scrotum; (5) undescended testes unless there is no response or an inadequate response to chorionic gonadotropin; (6) impotence which is not glandular in origin, and (7) old age complicated with arteriosclerotic or hypertensive heart disease.

Improvement from male sex hormone has been claimed in the following conditions, although the data are not extensive enough to warrant definite conclusions: (1) angina pectoris; (2) various menstrual disorders in the female including menorrhagia, metrorrhagia and dysmenorrhoea; (3) carcinoma of the ovaries, and (4) carcinoma of the breasts.

The administration of the male sex hormone may produce the following harmful effects: (1) injury to the normal testis with production of azoospermia: recovery from such injury usually follows the cessation of treatment; (2) symptoms of heart failure in old men; (3) pitting oedema of the lower legs; (4) acne vulgaris; (5) hypermetabolism (large doses), and (6) hypertrichosis, lowering of the pitch of the voice and enlargement of the clitoris in women.

Treatment of Postherpetic Pain

(Abstracted from the *Journal of the American Medical Association*, Vol. 133, 8th March, 1947, p. 733)

The treatment of chronic postherpetic pain is usually unsatisfactory. Before radical therapy is advised, the

following measures may be tried in the order recommended: (1) posterior pituitary injection once or twice in twenty-four hours, (2) quinine hydrochloride as tolerated, (3) two intravenous injections of sodium salicylate, (4) 150 mg. of thiamine hydrochloride hypodermically three times a week for at least four weeks and (5) cobra snake venom.

If these measures fail, the patient should be referred to a neurologic surgeon, who may do a root resection on the side of the involved area.

Reviews

AIDS TO MEDICAL DIAGNOSIS.—By G. E. Frederick Sutton, M.C., M.D. (Lond.), M.R.C.P. Sixth Edition. 1946. Baillière, Tindall and Cox, London. Pp. viii plus 308. Illustrated. Price, 6s.

THIS booklet in its various editions has been the backbone of the students' morale. That it takes a great man to write a small book has been exemplified by its authors.

The present edition is one of the best and includes the latest developments in medicine such as Rh, electroencephalography and atypical pneumonia.

Perhaps the best section deals with the nervous system and forms nearly a third of the whole.

The only serious omission appears to be the serological diagnosis of atypical anaemia (pp. 141-142) and the only obscurity concerns the age incidence of rheumatoid arthritis and osteoarthritis (p. 288).

The book can be safely recommended to the student and the busy practitioner who has not been able to follow up the recent developments in medicine due to the War and its aftermath.

The get-up is of the usual Aids series, the paper being a trifle thinner than usual, in keeping with the shortage.

S. D. S. G.

THE ESSENTIALS OF MATERIA MEDICA, PHARMACOLOGY AND THERAPEUTICS.—By R. H. Micks, M.D., F.R.C.P.I. Fourth Edition. 1947. J. and A. Churchill Limited, London. Pp. x plus 399. Price, 18s.

THE new edition of this very useful book is welcome. The author's aim in writing the book, as mentioned in the preface, 'has been to meet the requirements of students and practitioners more exactly than other textbooks by referring only to those drugs which are of real therapeutic value and presenting the information about them in such a way as to make the task of learning it as easy as possible'. In revising 'two aims have been kept in view—the exposition of the principles which govern the action of therapeutically important drugs and the guidance of the physician in their administration'. Within the limits set out by the author, he has signally succeeded in writing a book whose rational view-point, concise description and precise direction of administration of remedies make it very pleasant reading and easy to remember. Opinions regarding what are therapeutically important drugs will obviously differ for therapeutics is still an art rather than a science and some may consider that the book does not contain enough 'essential' materials for medical students appearing in Pharmacology and Materia Medica examinations of the Universities and other Medical Faculties. Many may not agree with the view about the decomposition products of haemoglobin on p. 204; Benadryl mentioned in the text has not been indexed. These are minor blemishes in an otherwise very useful and dependable book for practitioners and students appearing in therapeutics.

J. C. G.

AN INTRODUCTION TO DERMATOLOGY.—Formerly by Norman Walker, Kt., M.D., LL.D., F.R.C.P., and G. H. Percival, M.D., Ph.D., F.R.C.P.E., D.P.H. Eleventh edition, 1947, by G. H. Percival. E. and S. Livingstone Limited, Edinburgh. Pp. xii plus 349. Illustrated (mostly in colours). Price, 35s. Postage, 9d. (Home)

It is a treat to find Norman Walker's Introduction to Dermatology having another edition, the eleventh. This was the book which introduced me and some of my colleagues to the study of dermatology.

In the present edition the book has been reduced in size and many recent informations given; this is as it should be. But in this edition we miss badly Norman Walker's easy flow of words and story-like description of the diseases which made his book so popular to the beginners.

The chapters on the erythematous eruptions and the eczema are well written, well illustrated and instructive. But the chapters on avitaminosis and tropical skin diseases are disappointing.

The publishers deserve congratulations for the paper, printing, coloured plates and the get-up of the book.

L. M. G.

THE TREATMENT OF DIABETES MELLITUS.—By E. P. Joslin, A.M., M.D., Sc.D., H. F. Root, M.D., P. White, M.D., A. Marble, A.M., M.D., and C. C. Bailey, M.D. Eighth Edition. 1946. Henry Kimpton, London. Pp. 861. Illustrated. Price, 50s.

We welcome the eighth edition of Prof. Joslin's extremely illuminating monograph, which presents to us most interesting records concerning 29,000 diabetics over a period of 48 years . . . the biggest achievement which any single author could produce in his lifetime.

A new and a very interesting chapter has rightly been devoted to 'Alloxan' diabetes, which can be produced in experimental animals by the injection of a chemical 'Alloxan' with almost unbelievable specificity. Alloxan is the ureide of mesoxalic acid and can be produced by oxidation of uric acid or from barbituric acid and is a colourless powder easily soluble in water or alcohol. It has been shown to have a specific destructive action of the Beta cells of the islands of Langerhans and experimental diabetes in animals can be produced slowly or suddenly according to the dose given. This new discovery appears to us to be a very important one from the point of view of research work in experimental diabetes, mainly because it is so easy to perform and also because it has several distinct advantages over the other and older methods such as pancreatectomy or injections of crude pituitary extract.

The book is a mine of useful informations, being the product of Prof. Joslin's life-long and intensive study devoted to the problem of diabetes. It is recognized as a classical work and a standard book of reference particularly from the point of view of statistics, physiology and pathology of diabetes. The amount of important, useful and up-to-date observations made within its pages is amazing. It is a *vademecum* which we feel sure will prove to be a valuable book of reference for those engaged in the study of the subject.

J. P. B.

A MANUAL OF TOMOGRAPHY.—By M. Weinbren, B.Sc., M.R.C.S., L.R.C.P., F.F.R., D.M.R.E. 1946. H. K. Lewis and Company, Limited, London. Pp. viii plus 270. Illustrated. Price, 45s.

TOMOGRAPHY is one of the more recent developments of radiology. By a co-ordinated movement consisting of the x-ray tube, rotating on its axis, and the x-ray cassette moving in an opposite direction on a variable fulcrum, skiagrams can be taken concentrating on certain layers of the body with the blurring out of the layers above and below. In this way certain conditions can be demonstrated which otherwise are overlapped by other structures, and therefore more or less obliterated.

Dr. Weinbren has succeeded admirably in bringing out the value of tomography in a large number of conditions. In the lungs the demonstration of cavities whose outline may be occluded more or less by surrounding fibrosis is very well demonstrated. In one striking case the author shows up very clearly a peripheral emphysematous bulla being the cause of a recurrent spontaneous pneumothorax.

In the section on the chest there is a very interesting account of the tomography of various cardiac conditions.

An excellent chapter is devoted to the tomography of the spine, in which the author demonstrates very clearly by this method many conditions missed at routine radiography. One of those is the demonstration of a large secondary carcinomatous deposit in a vertebra, not seen in the ordinary skiagrams.

The section on the skull and facial bones gives an excellent account of the valuable information that can be obtained of the petrous bone and of injuries of the facial bones. The latter particularly are often overlooked owing to overlapping by other structures.

An interesting section deals with dislocations and fractures of the condyloid process of the mandible in examinations of the temporo-mandibular joint.

A miscellaneous section at the end of the book shows the value of tomography of a large number of conditions where it is desirable to see changes at a certain depth of the tissues. An interesting case is included here where a cholecystogram showed apparently normal appearances in the gall bladder, whereas tomography revealed a calculus.

An account is given of tomography of the larynx, which certainly does give some information to the clinician.

The concluding chapter of the book gives a clear and concise account of the technique used by the author.

This book is a most welcome addition to the library of any serious radiologist. The whole production is excellent, and the skiagrams illustrating it are admirably reproduced.

S. G. G.

AIDS TO QUALITATIVE INORGANIC ANALYSIS.—By R. G. Austin, B.Sc., F.R.I.C., F.R.M.S. Second Edition. 1947. Baillière, Tindall and Cox, London. Pp. xii plus 207, with 9 figures. Price, 5s.

This book is of great help to the student starting his university career. Identifying unknown inorganic radicals present in mixtures and compounds has been made easy for him.

The concise and pithy way of putting all the procedures in the separation of the various groups and sub-groups and the characteristic tests for all radicals given side by side dispel confusion and raise the morale of the young chemist.

The pocket size and good printing are attractive and the price is not unreasonable.

B. C. D.

ADVICE TO THE EXPECTANT MOTHER ON THE CARE OF HER HEALTH AND THAT OF HER CHILD.—By F. J. Browne, M.D., D.Sc., F.R.C.S.E., F.R.C.O.G. Eighth Edition. 1947. E. and S. Livingstone Limited, Edinburgh. Pp. 50. Price, 9d. Postage, 3d. (Home)

The book is in its eighth edition and written with the object of helping the mother in the care of herself and her unborn and born baby. Dr. Browne has justified his objective by putting forth his ideas in an easy and popular language that will appeal to the mothers. He is clear in his various practical suggestions.

The pregnant mother will get many solutions of her daily experiences which look like problems to her. Thus she will get both physical and mental comfort by following the advice given in the book. Questions on minor ailments, which form a major part of pre-natal clinic work, have been answered clearly. This will help

the mother to understand the advice of her doctor and nurse. The same thing applies to the infant care also. Dr. Browne's experience is reflected in all the simple practical guidance he has given to the mothers.

Not being voluminous it encourages one to read. Printing is in decent type which makes easy reading. The popularity of the book is demonstrated by the various editions it has gone through. The present one has been made up to date by incorporating the latest ideas on maternal health. One would like to see this book on the book-shelf of every home.

M. S.

MOTHERCRAFT IN THE TROPICS.—By Kennie Macpherson. 1947. Cassell and Company, Limited, London. Pp. xiv plus 205. Price, 6s.

THE author of the book has had first hand experience of the Tropics. It seems to have been written with the object of helping the Western mothers who come to live in the Tropics. For us who have been born and brought up in the Tropical soil, some of the problems mentioned seem to be a little exaggerated. None the less it will be able to guide many mothers coming to live under the new conditions.

The contents would have been more befitting the title, and would have been within the capacities of mothers if so much space had not been given to diseases and other topics of a technical nature. Some statements like the ones on feeding and immunity seem to be a little exaggerated and not quite correct.

The advice on the selection and the management of ayahs is a useful chapter. The stress laid on the need for regular medical examination is an encouraging one.

The book has been got up in a very attractive form and in bold type. Hence it is easy reading. The writing is in fairly popular language, and many practical points are given from the author's personal experience.

M. S.

CHILD HEALTH AND DEVELOPMENT.—By Various Authors. Edited by Richard W. B. Ellis, O.B.E., M.D., F.R.C.P. 1947. J. and A. Churchill Limited, London. Pp. viii plus 364. Illustrated. Price, 18s.

CHILD Health and Development is a book that will be very much appreciated by the Maternity and Child Welfare workers. The book gives the recent concepts of child health and development in its various fields. This helps the reader to save time and gain knowledge without having to refer to too many books. It is written in a way that will help the doctors, health visitors and others who have taken interest in this branch of preventive medicine.

Though the main subject of interest is the child, the subject of Maternity and Child Welfare has been considered as a continuous service in this book. This emphasizes the place and importance of the mother and her health in the care of her child. The stress on the need for considering the child as a living, thinking, and feeling being, with his own individual personality will impress all those who read the book. Social aspects of Child Health have also not been neglected. This is in keeping with the credit the book gets as being a modern one. The second part describes the relationship of social services to child care, along with the organization that exists at present. This will help many in planning Maternity and Child Welfare programmes.

The book has been nicely got up and in quite good print. It should find a place on the bookshelf of all those who are either interested or working in the field of Maternity and Child Welfare.

M. S.

THE CARE OF CHILDREN—FROM ONE TO FIVE.—By John Gibbens, M.B. (Camb.), F.R.C.P. (Lond.). Third Edition. 1947. J. and A. Churchill Limited, London. Pp. vii plus 192. Illustrated. Price, 5s.

THIS book supplements the book on care of babies by the same author. The two together give a conti-

uous picture of the citizen as he starts life and begins to understand and gets himself adjusted to his environment. It is intended for mothers and also for people who are interested in children and want to help them to grow up to the best of their capabilities. Mothers consider many small things as serious problems and they feel helpless and depressed when they cannot help their children. This book will give them many practical and easy suggestions in understanding children.

Training in good habits and showing co-operation in solving the child's day-to-day problems is essential at this age. Also as the child is more independent he is exposed to more hazards. Dr. Gibbens gives considerable importance to both these needs and tells us how to keep him busy and use his unlimited energy in a constructive way. The book will help the mothers to give the best they can to the children with whatever limited resources they have. Child Welfare workers will be able to get many hints as to the right approach to mothers, in language and thought that will appeal to them most.

The book is composed in an attractive and easy form. The illustrations are quite catching. It should be a popular book among all those who have to deal with children in one way or other.

M. S.

THE CARE OF YOUNG BABIES.—By John Gibbens, M.B. (Cambridge), M.R.C.P. (Lond.). Second Edition. 1946. J. and A. Churchill Limited, London. Pp. viii plus 200, with 7 plates and 7 text-figures. Price, 5s.

IN a popular language and in a practical way this book deals with babies. As mothers get more and more educated and the family gets smaller and smaller in our society, they want to know more and more about their babies. They want to give their best. The book will give them considerable practical hints for this purpose.

Starting with a note on the care during pre-natal period and then a word to the fathers, the book goes on to consider the babies, their needs and problems. At this period feeding causes anxiety to mothers in various ways and the section devoted to that subject has been adequate. The book will help her not only when the child is well, but will give her practical suggestions which she could easily carry out when the child is ill. Mothers should find this a helpful book and child welfare workers an easy guide for proper approach to the mothers.

It is a well got-up book with very attractive illustrations. Easy to read and easy to handle. Deserves to become a popular book among all those who want to know about babies and want to help them to grow up as useful and happy citizens of the nation.

M. S.

THE LOUSE. AN ACCOUNT OF THE LICE WHICH INFEST MAN, THEIR MEDICAL IMPORTANCE AND CONTROL.—By Patrick A. Buxton, C.M.G., F.R.S. Second Edition. 1947. Edward Arnold and Co., London. Pp. ix plus 164, with 47 figures and 9 tables. Price, 10s. 6d.

THE second edition of Prof. Buxton's book has been thoroughly revised and some chapters have been rewritten. The author has produced a treatise on the louse giving a comprehensive account of the subject.

The first two chapters deal with general biology and external and internal anatomy of the insect. The individual and collective biology is described in two separate sections. The relation of lice to relapsing fever, typhus and trench fever has been fully gone into, and up-to-date information of the development of rickettsia and spirochaeta in the louse together with short comparative descriptions of murine typhus and the tick-borne relapsing fevers has also been incorporated. The chapter on louse control has been rewritten and all the methods of delousing have been adequately described. A chapter on Phthirus and an appendix on the technique of rearing lice for experi-

mental purposes conclude the book. The illustrations are excellent.

D. N. R.

RECENT ADVANCES IN CLINICAL PATHOLOGY.—

Edited by S. C. Dyke, D.M. (Oxon.), F.R.C.P. (Lond.). 1947. J. and A. Churchill Limited, London. Pp. xii plus 468, with 34 plates and 19 text-figures. Price, 25s.

THE World War II brought together in England a number of clinical pathologists from Europe. They pooled their experience and wrote this book which is, thus, unique in conception and execution.

All recent additions to the subject of clinical pathology are included, e.g. Atypical Pneumonia (with details of serological diagnosis), Anaerobic Infections, Rh Factor, Blood Chemistry in Diseases of the Alimentary Tract, Semen Examination (histological and chemical), Biopsy (with observations on histological details which are by no means final) and Haematology (with observations on its recently acquired top-heaviness).

The only obscurity noted by the reviewer concerns the serological diagnosis of atypical pneumonia: it is not clear whether the agglutination titre is given by the *initial* or the *ultimate* dilution. It is given really by the initial dilution.

The index could have been fuller: semen which has been dealt with very well in the book is not found in the index.

The book is a very useful addition to the medical laboratory workers' literature. The get-up is compatible with the post-war dearth of paper, etc., and the price is reasonable.

S. D. S. G.

MEDICAL DISORDERS OF THE LOCOMOTOR SYSTEM INCLUDING THE RHEUMATIC DISEASES.—

By Ernest Fletcher, M.A., M.D. (Cantab.), M.R.C.P. E. and S. Livingstone Ltd., Edinburgh. Pp. xii plus 625, illustrated. Price, 45s.

THIS book deals in a comprehensive manner with all disorders of movements other than those arising from diseases of the nervous system.

Applied anatomy and physiology, radiography, laboratory findings and the author's system of examination are well described. Nine contributors have written special sections.

Although the bulk of the book deals with chronic rheumatism, rheumatoid arthritis, osteoarthritis and fibrositis, rare diseases like the 'marble bone' are also included. The classification followed is that of the Royal College of Physicians, London.

The treatment includes all up-to-date measures, physical, medical and surgical.

The paper, printing and binding are good. No printer's errors attract attention. The price is not unreasonable.

Abstracts from Reports

REPORT OF THE SCIENTIFIC ADVISORY BOARD, INDIAN RESEARCH FUND ASSOCIATION, 1946

THESE researches were carried out in various centres and many of them are still in progress. In the following summary only matters of general interest are referred to:—

Cholera.—Owing to its low incidence there was not enough opportunity to test the value of sulphadiazine in treatment. A chemical compound of sulphanilamide and formalin, designated 'FSA PPT', is being worked out for treatment of the disease; it has a more marked bacteriostatic, though not selective, action on the vibrios than sulphaguanidine or sulphasuxidine.

Malaria.—Work on D.D.T. continues. From certain field trials it is concluded that (1) indoor residual spraying is the most effective method against mosquitoes and (2) for residual spraying, emulsions (oil in water) and suspensions (in water) containing 2.5 per cent D.D.T. and applied at the rate of 2 c.c. per square foot are highly effective. Enquiry on mammalian malaria has so far shown no evidence of the existence of exo-erythrocytic cycle. **Nutrition.**—The effect of including khesari gram (*Lathyrus sativus*) in diets containing adequate quantities of vitamins was

that guinea-pigs did not grow and developed certain toxic symptoms suggesting toxic effects. In another experiment done elsewhere the addition of this cereal (30 per cent) in the diet of pigeons seemed to show a distinct tendency towards the development of lathyrism but this was mitigated to a certain extent by the administration of vitamin A. The clinical features of riboflavin deficiency were found in Madras not only in the mouth, tongue and eyes but also manifested as fissure, proctitis, angular blepharitis and preputial ulceration. Phrynoderma was found more often related to vitamin B complex deficiency, responding well to a combination of yeast extract and linseed oil. 'Burning feet' was relieved by marmite and injection of calcium pantothenate and not by thiamine, nicotinic acid and riboflavin. The vitamin A content of shark liver oil obtained from various places in India has been found to vary considerably. The kernel of coconut has 8.27 per cent crude protein but is poor in many vitamins. It has been proved that with the increase of nitrogenous manures the protein content of rice also rises much above the normal value. The mineral and vitamin contents of such rice are being estimated. A study of the effect of strain and environmental factors has shown that the nutrition value of some cereals and pulses is greatly influenced by the genetic nature of

the strain and emphasizes the need for new strains as a step forward towards the development of nutrition of this country. Peels from oranges and citrus fruits were found to be exceptionally rich in carotene. Experiments with soya bean continue and many leafy vegetables are being analysed for their vitamin content. Investigations are proceeding on fat metabolism, food supplements, value of food protein in the regeneration of blood and of plasma proteins, etc. A note is appended to the report on vanaspathi or hydrogenated vegetable oil which, though more or less devoid of vitamins A and D, appears to have good nutritional value, but its melting point should not exceed 38°C., otherwise the digestibility and absorption decreases. Further researches on it are needed. In the practical field Bombay Government has taken various steps, viz, supply of groundnut cake atta at cheap rates (this can be mixed with ordinary wheat atta for making chapattis), extension of milk scheme, preparation of vitamin A concentrates from shark liver oil, sale of vegetables through Government shops and extension of community feeding and canteens in industry. Work in Madras has included free mid-day meals for school children, free milk supply to priority consumers, etc. In Hyderabad-Deccan a mobile canteen scheme is in operation with demonstration kitchens and supply of balanced nutritious meals at cost price. *Leprosy*.—The sulphone drugs, promine and diosone, are being tried. Most patients have shown clinical improvement but have not been bacteriologically negative. In a few treatment had to be discontinued because they could not stand it. Attempts are being made to get streptomycin and try it in this disease. A study of about 2,000 cases of leprosy showed, contrary to general belief, that it was rare to find lepra bacilli in the nose in the absence of bacilli in the skin. *Plague*.—Experiments with DDT on rat fleas are being continued. It is noted that plague vaccine grown in casein hydrolysate is more potent and has greater virulence than agar-grown vaccine. *Clinical*.—B levels were determined and found to show a significantly lower range in oral cancer than in healthy people. In the acute stage of naga sore fusiform bacilli were found constantly in enormous numbers; they seem to be of aetiological importance. Typical ulcers could be produced in human volunteers by intradermal inoculation of the pus. A survey of some estates showed that the affected people were mostly engaged in outdoor work and the ulcers were due to the trauma of the lower extremities. In many there was history of trauma at the site of ulcers; in others vesicles or papules appeared spontaneously with itching. Insects probably played no part in the causation of the disease. Its incidence was related to rains only in some cases, and while occurring sporadically in one tea garden, it may occur in epidemic form in a contiguous one for no apparent reason. Blood proteins in healthy people, in certain tropical diseases and in persons suffering from malnutrition were studied, and emphasis is given in the report of frequency with which severe hypoproteinaemia has been induced by the restriction of diet under medical advice, a condition which can be restored to normal by liberal feeding alone with no special medicinal treatment. In the treatment of hypoproteinaemia the oral administration of protein appears to be the best method of treatment when patients are able to take diet by mouth. A study of the anatomy of foot by making cross sections at various levels showed some additional fascial spaces besides the known ones; this may help to get a clear understanding of the infection in foot and leg. Investigations are proceeding on the rôle of nutritional factors in hepatic cirrhosis and on the aetiology and treatment of infantile cirrhosis. A survey by the newly constituted dental research unit revealed a low incidence of dental caries and a very high incidence of parodontal diseases in Ajmer-Merwara province and that endemic fluorosis is common in many parts of the Punjab. Some investigations were also carried out by the unit on dental dystrophies in infantile scurvy and parodontal diseases. An enquiry into the causes of blindness shows that it is preventable in at least 38 per cent of cases. *Pharmacology*.—Some

are being studied. *Maternal and* enquiry is being made on the bearing of premature and immature births on infant mortality. *Filaria*.—Study of the action of antimony compounds, stibatin and anthiomaline was continued. *Other researches*.—These were on folic acid on macrocytic anaemia, filtrable viruses, serological diagnosis of typhus fever, manufacture of penicillin, etc.

Old Tales Re-told With Fresh Comments

OLD CALCUTTA (1759-1763)

By C. CLEGHORN

(From 'Selections from Unpublished Records of Government for the years 1748-1767 inclusive'. By the Rev. J. Long, member of the Govt. Record Commission, Vol. 1, 1869, Office of the Superintendent of Govt. Printing, Calcutta, 1869)

Servant's wages

THE following is quoted from proceedings of the 21st May, 1759 :—

Taking into consideration the united complaints of the inhabitants (of Calcutta) with respect not only to the insolence but exorbitant wages exacted by the menial servants, and having duly weighed and considered the premises, we are of opinion that their complaints are too justly founded and loudly call for redress. That a rate of monthly wages be established according to the underwritten lists of servants in private service.

	Rs. As. P.		Rs. As. P.
Consumah		Peon	
Head cook		Bearers	2 8 0
Coachman	5 0 0	Washerman ..	3 0 0
Female servant		Molly ..	2 0 0

Scarcity of grain

A Government note dated the 20th July, 1761, states :—

The scarcity of grain in the place (Calcutta) being at present such as to distress the poorer sort of people in the greatest degree, in order therefore to relieve the wants of the poor, the Board propose sending a sum of money to the markets in the country for the purchase of a quantity to be sold at an easy rate.

[It will be observed that the exaction was followed by the scarcity of grain, not unlike what is happening at the present time. It was a man-made scarcity. Obviously the establishment of the wages in 1759 was not rigid enough.—EDITOR, I.M.G.]

Correspondence

ABORTION BY MEDICAL PROFESSION

SIR,—The mass migration resulting due to the division of India has not left the medical profession unconcerned.

The threat of the epidemics and heavy casualties resulting by the madness seizing the population in Punjab, has no doubt called for the utilization of all the available means with the Directorate of Health Services.

But this is not all. The abduction of innocent womenfolk of opposite communities and their being rendered *enceinte* presents an angle which has not only socio-religious bearing but its medical aspect too. What should be the position of such women who have been subjected to such brutal experience of course against their wishes? In a letter to the *Hindustan Times*, New Delhi, a plea has been made that abortion should be undertaken by the medical profession with justification and I hope others too agree with me that such a step is justified and necessary.

Perhaps I will do well to cite as a parallel to such an action the case of Dr. Alec Bourne a leading Harley Street specialist in Obstetrics and Gynaecology who on seeing a case of a young girl of 14 years of age becoming pregnant after being raped by soldiers decided to do an abortion on his own judgment considering the grave consequence were the pregnancy allowed to go to full term. Dr. Bourne informed the police authorities in advance of the time and place and his intention to abort the girl. The police arrested him and in the trial that followed Dr. Bourne was not only honourably acquitted but the magistrate complemented him for his judgment and foresight. The medical profession therefore need have no qualms in resorting to such a step in suitable cases.

I am, etc.,

One of the Medical Profession.

[We agree. See editorial.—EDITOR, I.M.G.]

OLDEST MEDICAL MONTHLY OF THE EASTERN HEMISPHERE

SIR,—As a regular reader of your esteemed journal I want to draw your attention to a small error in your Editorial in the June 1947 issue (page 346), where under the heading 'The Twin Dominions and the Indian Medical Gazette' you state:

'The first number of this publication appeared in 1860. . . . This journal is the oldest medical monthly of the Eastern hemisphere. . . .'

Doubtless this is true as regards English-speaking countries in the Eastern hemisphere, but nevertheless, the 'Geneeskundig Tydschrift van Nederlandsch-Indië' (Medical Journal of the Netherlands Indies) is 9 years older than the *Indian Medical Gazette*. This periodical, issued at first bi-monthly, later monthly, and finally weekly, was edited regularly from 1851 till 1942; then came the Japanese occupation, whereby the journal was suspended. At present it is issued again as *Medisch Maandblad* (Medical Monthly).

Yours, etc.,

Ch. W. F. WINCKEL,
former Editor of the
Geneeskundig Tydschrift
voor Ned.-Indië.

AMSTERDAM Z,
DE LAIRESSESTRAAT 142,
10th October, 1947.

[The statement under objection is amended as follows:

The journal is the oldest medical monthly of the Eastern hemisphere, that has been issued regularly up to date since its commencement. . . .

Incidentally, the date of publication of the first number of this publication is 1856 and not 1860.

—EDITOR, I.M.G.]

STORAGE OF PENICILLIN

SIR,—With reference to the letter from Major Bouche which appeared in your issue for May 1947, and the editorial comment upon it, we would refer you to a more recent paper by Denston (*Quart. Journ. Pharm. and Pharmacol.*, 1946, XIX, 322). She studied the stability of solutions of penicillin at different temperatures and from which withdrawals were made at intervals to reproduce the storage conditions in practice of solutions of penicillin.

Penicillin 'Glaxo' as obtained in India has a high potency, usually at least 1,400 units per mg.; the following observations are based on material of such potency.

The majority of specimens stored at room temperature in Bombay (85°F.) show little appreciable loss after 6 months. An imperfect closure, resulting in access of moisture, will adversely affect the keeping properties.

It may therefore be said with some confidence that cold storage in hill stations is not necessary.

Penicillin solutions may be stored at room temperature up to 100°F. for 4 days without appreciable loss of activity. We suggest that estimates of keeping properties for longer periods are largely academic as solutions are seldom likely to be kept longer in medical practice.

Denston found that a solution of high potency penicillin of 100,000 units per mil. has 90 per cent of the original potency after five to six days whether stored in a refrigerator or at room temperature (70°F.). After ten to fourteen days in a refrigerator 85 per cent of the activity can be guaranteed.

We would draw attention to the apparent misprint in the second paragraph of the comment on penicillin powder, where 8°C. not 80°C. is surely intended.*

The statement that refrigerator temperature is 2°C. is a little misleading; the storage temperature in the ordinary domestic refrigerator is usually about 8°C.

Yours faithfully,

H. J. FOSTER & CO., LTD.

BOMBAY 1.

[*This printing error is regretted.—EDITOR, I.M.G.]

USE OF ANTICOAGULANTS IN THE TREATMENT OF EXPERIMENTAL YELLOW FEVER

SIR,—Almost 40 years ago Calmette (1908) noted that lesions resulting from the injection of viper venom 'Strangely resembled those observed in the case of individuals who have died from yellow fever'. Calmette further remarks that this observation was made by several scientists, notably Sanarelli, and that it had probably led Dyer and Bettineour 'to treat—without much success—yellow fever by the 'antitoxin of venom'.

It is not surprising that antivenene should be of little or no value in the treatment of yellow fever despite similarity in the pathology of the two conditions, for such sera are, of course, purely specific in action. Nevertheless, if the action of yellow fever virus resembles that of viper venom, it may be that a non-specific physiological antidote to venom will be of some value as an antidote to the action of the virus.

In heparin (and possibly dicoumarol) we have a physiological antidote to the venom of the Russell's viper (*daboia*), as recently shown by Ahuja and others (1946). On purely theoretical grounds unsubstantiated by any experimental work on our part, we suggest the use of these anticoagulants in the treatment of experimental yellow fever in animals.

We apologize for so speculative a theory, but as we are precluded from experimentation on yellow fever in India, we write in the hope that someone in a position

to conduct such work may see this letter and give the suggestion a trial.

Yours faithfully,
M. L. AHUJA,
LIEUTENANT-COLONEL, late I.M.S.,
Director, Central Research
Institute, Kasauli,
A. G. BROOKS,
Assistant Surgeon, I.M.D.

Any Questions

BLOOD AND PLASMA TRANSFUSIONS

SIR,—In the rural areas of Bengal it is practically impossible to practise blood transfusion in cases of severe blood loss and anaemia, because the facility of laboratory for grouping is not available.

Is it possible for us to practise plasma transfusion (dried plasma) instead of whole blood transfusion without the help of a laboratory? If so, please let me know the source of supply, technique and other details of the same, and also reference books if any on the subject.

Yours faithfully,
KAMALAPATI CHATTERJEE, L.M.F.

P. O. BHANDARJHI
(Dist. BURDWAN).

[Dried plasma is made up to the original potency according to the instructions sent with the bottle.

The Blood Bank, Calcutta, provides dried plasma. The Bank will also provide the other information you desire.

The work of blood transfusion and blood banks was discussed in the editorial of *I.M.G.*, August 1947.—

Service Notes

APPOINTMENTS AND TRANSFERS

In view of the partition of the province, Lieutenant-Colonel E. G. Montgomery, who has chosen to serve in East Bengal, is transferred in the interest of public service as Surgeon-General, Dacca, with effect from the 15th August, 1947.

The services of Major F. M. Khan, Port Health Officer, Calcutta, are placed at the disposal of the Government of Bengal, with effect from the 24th June, 1947, for appointment as Director of Public Health, Bengal.

Major F. W. Allinson, Surgeon-Superintendent, Presidency General Hospital, Calcutta, is appointed to be Professor of Surgery, Dacca Medical College.

Major J. W. D. Goodall, Professor of Clinical Medicine, Medical College, Calcutta, is appointed as Civil Surgeon, Dacca, vice Dr. Md. Refatullah.

The Secretary of State for India has appointed to the Indian Medical Service (Civil) the following officers of the Indian Medical Service with effect from the dates noted against their names:—

External Affairs and Political Departments

Captain T. P. Binns. Dated 25th August, 1943.
Major D. P. Dewe. Dated 24th May, 1946.

Health Department

Major M. S. Chadha. Dated 9th May, 1945.
Captain P. J. Wormald. Dated 1st September, 1945.
Major B. S. Khurana. Dated 12th October, 1945.
Major P. M. Kaul. Dated 24th January, 1946.
Captain K. D. Fraser. Dated 24th May, 1946.

Assam

Captain J. R. Kerr. Dated 21st December, 1945.
Captain J. Lightbody. Dated 7th April, 1946.

Bengal

Major K. N. Rao. Dated 26th March, 1946.
Major A. V. O'Brien. Dated 17th May, 1946.

LEAVE

Major W. J. Virjin, Principal, Dacca Medical College, is granted leave for 8 months with effect from the 1st August, 1947.

Colonel L. K. Ledger, C.I.E., O.B.E., Inspector-General of Civil Hospitals, C.P. and Berar, granted leave on average pay for 8 months combined with leave on half-average pay for 9 months and 1 day with effect from 11th August, 1947, preparatory to retirement.

Lieutenant-Colonel A. S. Garewal, Inspector-General of Prisons, C.P. and Berar, is appointed to hold the charge of the office of the Inspector-General of Civil Hospitals, C.P. and Berar—*cum*—Director of Public Health, C.P. and Berar, in addition to his own duties with effect from 11th August, 1947, forenoon.

Lieutenant-Colonel C. H. Dhala, now on training at the Presidency Jail, is allowed leave for 4 months with effect from the 12th August, 1947.

Lieutenant-Colonel D. Kelly, Civil Surgeon, Chhindwara, is granted leave on average pay for 8 months combined with leave on half-average pay for 20 months preparatory to retirement with effect from 14th August, 1947, forenoon.

Colonel D. Clyde, C.I.E., V.R.S., Surgeon-General with the Government of Bengal, is granted leave for 3 months with effect from the 15th August, 1947.

Lieutenant-Colonel C. L. Pasricha, Director, School of Tropical Medicine, Calcutta, is granted leave for 4 months with effect from the 15th August, 1947.

Major A. T. Andreasen, Professor of Surgery, Medical College, Calcutta, is granted leave for 28 months with effect from the 15th August, 1947.

Major V. M. Albuquerque, O.B.E., Medical Planning Officer, is granted leave for 6 weeks with effect from the 15th August, 1947.

Lieutenant-Colonel E. A. R. Ardeshir, whole-time Superintendent and Medical Officer, Presidency Jail, is allowed leave for 4 months with effect from the 26th August, 1947.

Lieutenant-Colonel B. Choudhury, O.B.E., Deputy Inspector-General of Prisons, West Bengal (Security), is allowed leave for 8 months with effect from the 26th August, 1947.

Lieutenant-Colonel M. A. Singh, Inspector-General of Prisons, West Bengal, is allowed leave for 4 months and 15 days with effect from the 26th August, 1947.

PROMOTIONS

Majors to be Lieutenant-Colonels

G. K. Graham. Dated 3rd August, 1947.
P. L. O'Neill. Dated 5th August, 1947.

Captains to be Majors

W. H. A. Thorne, O.B.E. Dated 1st May, 1947.
C. C. Harvey. Dated 1st July, 1947.
R. J. McGill. Dated 1st July, 1947.
H. N. Sen Gupta. Dated 12th July, 1947.
N. Jungalwala, O.B.E. Dated 1st August, 1947.

RELINQUISHMENTS

The undermentioned officers are permitted to relinquish their commissions on release from army service and are granted the honorary rank of Lieutenant-Colonel:—

INDIAN LAND FORCES—INDIAN MEDICAL SERVICE
SECONDED TO THE INDIAN ARMY MEDICAL CORPS

(Emergency Commissions)

Ty. Lieutenant-Colonel T. M. Mathew. Dated 22nd April, 1947.

Major R. B. Sule, Medical Adviser (Pensions) (D.A.D.M.S.), Defence Department (Pensions Branch), relinquished the appointment. Dated 8th June, 1947.

The undermentioned officers are permitted to relinquish their commissions on release from army service and are granted the honorary rank of Major:—

INDIAN LAND FORCES—INDIAN MEDICAL SERVICE
SECONDED TO THE INDIAN ARMY MEDICAL CORPS

(Emergency Commissions)

Major N. S. Pillay. Dated 11th August, 1946.

Captain K. Mariswamappa. Dated 12th April, 1947.

Major S. Mascarenhas. Dated 21st April, 1947.

Ty. Major P. Ray. Dated 2nd May, 1947.

Ty. Major C. Joseph. Dated 26th May, 1947.

Major C. R. Mannadiar. Dated 6th June, 1947.

Major H. M. Kalapesi. Dated 7th June, 1947.

Major A. Kidvai. Dated 12th June, 1947.

Major N. K. Roy. Dated 26th August, 1947.

The undermentioned officer is permitted to relinquish his commission on release from army service and is granted the honorary rank of Captain. His services are placed at the disposal of the Government of Punjab with effect from the date specified:—

INDIAN LAND FORCES—INDIAN MEDICAL SERVICE
SECONDED TO THE INDIAN ARMY MEDICAL CORPS

(Emergency Commission)

Ty. Major Akhtar Hussain Hamid. Dated 3rd April, 1946.

The undermentioned officer is permitted to relinquish his commission on release from army service and is granted the honorary rank of Captain. His services are replaced at the disposal of the Government of Assam with effect from the dates specified:—

INDIAN LAND FORCES—INDIAN MEDICAL SERVICE
SECONDED TO THE INDIAN ARMY MEDICAL CORPS

(Emergency Commission)

Captain Pramendra Nath Bhattacharjee. Dated 9th April, 1946.

The undermentioned officer is permitted to relinquish his commission on release from army service and is granted the honorary rank of Captain. His services are placed at the disposal of the Government of United Provinces with effect from the date specified:—

INDIAN LAND FORCES—INDIAN MEDICAL SERVICE
SECONDED TO THE INDIAN ARMY MEDICAL CORPS

(Emergency Commission)

Captain Bisheshwar Dayal. Dated 15th April, 1946.

The undermentioned officer is permitted to relinquish his commission on release from army service and is granted the honorary rank of Captain. His services are replaced at the disposal of the Government of Madras with effect from the date specified:—

INDIAN LAND FORCES—INDIAN MEDICAL SERVICE
SECONDED TO THE INDIAN ARMY MEDICAL CORPS

(Emergency Commission)

Captain Akkana Pragada Rama Mohan Rao. Dated 14th June, 1946.

The undermentioned officers are permitted to relinquish their commissions on release from army service and are granted the honorary rank of Captain:—

INDIAN LAND FORCES—INDIAN MEDICAL SERVICE
SECONDED TO THE INDIAN ARMY MEDICAL CORPS

(Emergency Commissions)

Captain K. S. Sarangapani. Dated 31st August, 1946.

Captain G. Singh. Dated 26th November, 1946.

Captain A. N. De. Dated 18th December, 1946.

Captain A. Mukherjee. Dated 11th January, 1947.

Captain M. Jogarayan. Dated 19th January, 1947.

Captain K. C. Dobhal. Dated 2nd April, 1947.

Captain E. Bheemasankaran. Dated 13th April, 1947.

Captain J. J. Poorvattil. Dated 5th May, 1947.

Captain H. D. Messiahdas. Dated 7th May, 1947.

Captain B. K. Rao. Dated 22nd May, 1947.

Captain K. A. Rao. Dated 23rd May, 1947.

Captain N. K. Shroff. Dated 10th June, 1947.

Captain T. V. N. Nambiar. Dated 20th June, 1947.

Captain G. Singh. Dated 22nd June, 1947.

Captain A. Sen Gupta. Dated 26th June, 1947.

Captain M. Swaminathan. Dated 26th June, 1947.

Captain M. Ismail. Dated 30th June, 1947.

INDIAN MEDICAL SERVICE

SECONDED TO THE INDIAN ARMY MEDICAL CORPS

*(Emergency Commissions)**(WOMEN'S BRANCH)*

Captain (Mrs.) Winifred Agnes Fernandez (*née* Vaz). Dated 1st May, 1946.

Captain (Miss) J. B. Hakim. Dated 29th October, 1946.

Captain (Mrs.) Lucy Achamma Kuruvilla (*née* Verghese). Dated 17th February, 1947.

Publishers' Notice

SCIENTIFIC Articles and Notes of interest to the profession in India are solicited. Contributors of Original Articles are entitled to receive 25 reprints *gratis*; additional reprints can be obtained on payment. No reprints will be supplied unless contributors ask for them at the time of submitting their manuscripts.

The preparation of reprints entails rearranging the type, so that there is often a delay of a month or more, after the publication of the *Gazette*, before the reprints are ready. If reprints are not received within two months of publication of the *Gazette*, contributors should write to the Publishers.

Papers and articles forwarded for publication are understood to be offered to *The Indian Medical Gazette* alone, and any breach of this rule will be followed by non-publication. When any such article appears in *The Indian Medical Gazette*, the copyright automatically becomes the joint property of the author or authors and of the publishers.

Communications on Editorial Matters, Articles, Letters and Books for Review should be addressed to THE EDITOR, *The Indian Medical Gazette*, c/o The Calcutta School of Tropical Medicine, Central Avenue, Calcutta.

Communications for the Publishers relating to Subscriptions and Advertisements should be addressed to THE PUBLISHERS, *The Indian Medical Gazette*, P. O. Box No. 54, Calcutta.

Annual Subscription to '*The Indian Medical Gazette*', Rs. 16 including postage, in India. Rs. 19-8 including postage, abroad. Single copies Re. 1-8 each. Back numbers (if available) for the previous year Rs. 2-8 each, and all other back numbers Rs. 5 each.

The Editors of *The Indian Medical Gazette* cannot advise correspondents with regard to prescriptions, diagnosis, etc., nor can they recommend individual practitioners by name, as any such action would constitute a breach of professional etiquette.

REITER'S DISEASE

By P. N. BARDHAN, I.M.S. (Singapore),

F.R.C.P. (Edin.)

MAJOR, I.M.S.

(From a Combined Military Hospital, India Command)

Introduction.—Differential diagnosis in medicine is emphasized primarily to ascertain the correct diagnosis so that correct treatment can be initiated. In conditions simulating venereal diseases the differential diagnosis has an added importance in that an incorrect diagnosis may lead not only to faulty treatment but also to much unnecessary mental distress to the patient as well as to his friends because of the stigma associated with venereal diseases. Gonorrhœa is one of the commoner VD's, and gonorrhœal urethritis complicated by poly-arthritis or bilateral conjunctivitis or both is not an uncommon clinical condition. Any other clinical condition giving a similar picture should therefore be well known so that a wrong diagnosis of VD does not add mental pain to the bodily pain of the disease. Reiter's disease is such a condition.

Literature.—Reiter (1916) first described the condition in a German officer aged 28 who was observed in a field hospital for thirteen weeks. The officer was not recently exposed to infection. On 21st August, 1916, he had lower abdominal pain followed by bloody diarrhœa. On 29th August, 1916, there appeared purulent urethritis and bilateral purulent conjunctivitis. On the next day an occasional joint was affected. During the 13 weeks in hospital the patient often had high temperature and delirium, and altogether had a severe illness. This severity of the illness is important to remember for the later cases have not been severe. At the time of discharge the officer was not materially improved. Reiter found a spirochæte from the blood of the patient, but this observation has not been repeated by any one else.

Reiter (1917) wrote again and was soon followed by others, mostly from Germany and Scandinavia. Cases were also reported from France and West Africa, 1916, 1917 (Editorial, 1946) and then a lull followed. Vallee (1946) referred to 151 cases, and Touraine and Ruel (1946) considered that 300 cases had been reported in the literature. They also called the condition 'pseudo-gonococcal enteritis' while Sargent (1945) proposed the term 'idiopathic blennorrhœal arthritis'. During the recent war years cases have been reported more frequently in British journals and the *British Medical Journal* (7th December, 1946) gives a review in editorial columns. The condition has not yet been

reported in this country and this paper includes four case records.

The clinical picture is characterized by a triad of urethritis, bilateral conjunctivitis, and arthritis. Pyrexia of varying degree is nearly always present. The pain of gonococcal urethritis is generally not seen, and hæmaturia has been infrequently reported. The case is generally seen in men, probably because women with such complaints care less to come forward for treatment. Associated features are iritis, scleritis, keratitis, keratoderma blennorrhagica, neutrophil leucocytosis to a moderate degree, general lymphadenitis, and raised erythrocyte sedimentation rate. Though earlier cases were linked with venery (Kristjansen, 1930), modern opinion (Editorial, *loc. cit.*) holds that there is no relationship to sexual intercourse. The conjunctivitis is purulent or muco-purulent, and is generally bilateral. Arthritis affects all joints though the larger more frequently. There is often fluid in the joints and the clinical picture is sometimes like that of rheumatic fever, except that the case is not so ill as in rheumatic fever. Epstein (1939) has thought that keratoderma blennorrhagica is part of the same illness. The disease may run its course without all the components of the main triad being present at the same time (Jackson, 1946). The disease if long drawn is self-limited. A mild hypochromic anæmia is part of the picture as would be expected from the toxæmia and the pyrexia; recurrence is a marked feature.

Case records.—The first case was seen in a male Chinese day-labourer aged 34, who was admitted into hospital in 1934 for purulent urethritis and bilateral purulent conjunctivitis. Exposure to venery was admitted three weeks ago and the first symptoms appeared 17 days later. There was discomfort but not actual pain on micturation, grittiness in the eyes, and slight general malaise. It was the fear of gonorrhœa that impelled the man to seek admission. The provisional diagnosis was gonococcal urethritis followed by contact or hæmatogenous conjunctivitis. Gonorrhœa was rife in the area and also in the particular class the man came from.

The standard treatment for gonorrhœa in the particular clinic at that time consisted of strict rest in bed, large amounts of fluid by mouth, mild alkalization of the urine for 72 hours, a low protein diet, camphor mono-bromide at night to prevent erections which would be painful, bi-weekly injections of 5 c.c. of 5 per cent trypaflavine intravenously, and symptomatic treatment for complications. The conjunctivitis in this case was treated with washes of 1 in 8,000 solution of oxycyanide of mercury. Irrigation of the urethra was rarely advised. While this accepted line of treatment was instituted in the case, the consistently negative findings for gonococci in the many specimens taken from the urethral and conjunctival discharge, as well as from the urine nullified the provisional

diagnosis of gonococcal infection. The diagnosis was made only later after reference to the literature.

For the first four days the treatment was attended with success in that the eyes cleared up completely and the urethral discharge was less. But on the fifth day the patient developed arthritis, one joint after another being involved and the affection apparently moving from joint to joint as in rheumatic fever. The urethral discharge waxed and waned and together with the flitting arthritis kept the patient in hospital for nearly three months. Syphilis had in the meantime been excluded, and the treatment was essentially symptomatic. A course of mixed vaccine produced little benefit, and ultimately the patient recovered after six bouts of hyperpyrexia produced by intravenous injections of Dmelcos. It was not claimed at the time, nor is it claimed now, that the Dmelcos was either specific or necessarily curative in the case. At the time of discharge the man was free of all symptoms and the joints allowed free movement.

Complement-fixation test was not done, but the large number of smears producing the negative results left no doubt that gonococci were not associated with the case. In spite of the length of the illness, the man was never very ill, and the highest recorded temperature was 103°F. once, and generally it was of the order of 100°F.

The second case was seen in a British Army officer in India in 1938. The man was 29 and had within the month previous been exposed to VD but he had taken all precautions. His presenting feature was arthritis of the right knee joint, but it was the onset of urethritis two days later that was the real reason for calling in the doctor. The story of the man if to be believed *in toto* meant that gonorrhœa was unlikely in view of the precautions taken, and yet there was no other obvious diagnosis. The eyes were affected two days later by a mildly purulent conjunctivitis and the case remained in hospital for eight weeks, though not always confined to the bed. The patient was never very ill; the other joints affected were the left wrist and the right foot. Gonococci were not demonstrated in spite of many examinations of the various exudates. The WR and the Kahn test were negative, and the urethritis was only anterior as judged by the three glass test. The leucocyte count was 12,500 with 73 per cent neutrophils. The pyrexia was only mild and the patient was more inconvenienced than ill. When discharged after eight weeks he was fully cured and has since served with an active regiment under diverse conditions and has remained perfectly fit. He was fit and active in 1945, obviously fully cured.

The third case was seen in an Indian soldier in Palestine. This man had never exposed himself to venereal diseases and he had had no dysentery during the three years of his service, one of which was spent in Palestine. The onset was sudden following an unusually hard day's

work. An itchy sensation was noted in the urethra for a few hours and taken little notice of. The next day there was slight malaise and in the evening there was noticed for the first time a little whitish discharge from the urethra. The patient began to suffer more from a sense of shame which he felt than from the actual illness. For the first three or four days it was impossible to assure him that he was not suffering from gonorrhœa; in fact members of the staff themselves were not satisfied that it was really not gonorrhœa. With sulphapyridine in the usual standard doses the urethritis improved, and even as it did, arthritis appeared. The right knee, the right ankle, and the left elbow were affected in rapid succession. There were swelling, warmth, pain, tenderness, and limitation of movement in all the joints. There was also slight bilateral conjunctivitis for five days, three days after admission. This feature did not become very prominent perhaps because the patient was receiving sulfapyridine at the time. In addition the eyes were washed with mild antiseptics. That the condition was not due to a gonococcal infection was certain, for the large number of specimens from the urethral and conjunctival discharge were negative for gonococci. The possibility of a chemical urethritis was carefully excluded. Once the joints were affected the treatment was suitably modified and the patient was in hospital for just over five weeks. The hæmoglobin came down from normal to 10.8 grammes per cent, rbc to 3.8 millions, and the wbc count varied from 11,000 to 13,000 with eosinophils varying from 5 to 9 per cent. This was a mild eosinophilia but is mentioned because this has not been noted in any of the other cases, and because the patient was not infested or infected with any parasites, to explain the finding. The complement-fixation test for gonococci was negative, and the WR and the Kahn test done twice were also negative. At the time of discharge the patient was well except for the mild anæmia and a faint stiffness in the joints affected. After a month in a convalescent depot the man was quite normal.

The striking feature of the case was the intense sense of shame from which the man suffered for a time, and to make matters worse people continued to joke about the affair for some time. This had to be stopped by orders, though later everyone knew that venery was not responsible for the illness.

The fourth case was a Bengali Muslim who was sent back from Malaya for a persistent urethritis and polyarthritis. He had been treated with sulfa drugs and also with 560,000 units of penicillin without result. He had denied exposure to venereal diseases but the clinical condition was too much like gonorrhœa for the treatment not to have been given. Gonococci were not found whilst overseas and repeated tests in India were also negative. On arrival in India the man was bedridden because of the joint affections but the urethral discharge

was quite minimal. Conjunctivitis was not noted in India but the field medical unit notes said 'Mild reddening of the eyes with slight discharge'. This was apparently treated though the notes said nothing more. The patient corroborated that eye washes were given. In view of the absence of gonococci and a negative WR and Kahn, Reiter's disease was diagnosed. Sepsis elsewhere in the body was excluded, and the fluid from the right knee joint was sterile. The x-ray pictures of the joints were normal. It is interesting to remember that other reports of cases also noted that there was no bony abnormality, and none made any specific reference to the synovial membrane. This patient remained in this hospital for over four months making a total stay in hospital for nearly six months. The treatment here consisted of physiotherapy, good dieting and nursing, careful diversional therapy, and another course of 800,000 units of penicillin. The net result was stoppage of the urethral discharge and some improvement in the general condition. But the progress was on the whole unsatisfactory. A mild hypochromic anaemia had developed, and after the second course of penicillin there was a fine scaly eruption in the soles of both feet. This was not actively treated and caused the patient little or no discomfort. Loss of weight was marked on arrival in India but was successfully countered by correct feeding. Specific enquiries were made about dysentery but any infection was denied by the patient.

Finally hyperthermia was produced by a series of intravenous injections of TAB vaccine, the actual doses given being 25, 25, 50, 50, and 100, and 250 millions of the standard vaccine intravenously, and other treatment such as careful nursing and diversional therapy were continued. Physiotherapy was continued and the patient made slow but steady recovery. On discharge he was, apart from the vague stiffness of the joints, quite fit and after another six months wrote to say that he was fit but thought that he had lost much of his manhood. He was then lost sight of because of demobilization.

Etiology.—The cause of the disease is still unknown nor is it clear whether this is a separate disease entity or is merely a syndrome which can be produced by a number of causal factors. The neutrophil leucocytosis, the pyrexia, the response to sulfa drugs and penicillin, and the similarity to other infectious diseases are all in favour of the condition being an infective process. But no one organism has been found in the exudates of the cases; in fact most of the cases showed sterile exudates. The original finding by Reiter (1916) of the 'spirochæte forans' has not been confirmed by any later finding of a similar organism from any of the other cases reported so far. A number of writers (Editorial, 1946) has correlated the disease with bacillary dysentery and Reiter's first case was associated with bloody diarrhoea; Jackson (1946) has, however, reported

cases which were in no way connected with bacillary dysentery. None of the cases in the present series was associated with bacillary dysentery. A strong argument against bacillary dysentery being a necessary causal factor in the production of Reiter's disease is the fact that while bacillary dysentery is very common in India, Reiter's disease is very uncommon.

In two of the three cases reported by Stühmer (1921) and in three of Sommer's (1918) cases no organism was detected, though it was considered that the urethral infection was the primary condition and the affection of the eyes and the joints secondary. Wrigley's (1946) case was associated with sepsis in one ear and an abscess in one calf, but no specific organism was isolated. Junghanns's (1918) case was associated with a furuncle in the upper lip and the case was considered part of a general septic process. Frühwald (1927) described two cases in one of which the onset was with urethritis and in the other with joint pains; here too no specific organisms were shown. In all these cases not only was no specific organism found, but what is more important still was the fact that gonococci were absent. The complement fixation wherever done was consistently negative for gonococci.

A virus infection is a possibility and Harkness (1945) claims to have demonstrated inclusion bodies in the exudates in five of his cases. This observation awaits confirmation.

Allergy as a causative factor has been hinted at by Denfield (1946) who observed cases in West Africans. He found that it required more than one and often several attacks of gonorrhoea to provoke an attack of Reiter's disease, and once provoked subsequent attacks of gonorrhoea made the Reiter's disease worse. The absence of eosinophilia is rather against allergy, though in the present series a mild eosinophilia was seen in one case. On the other hand the case described by Forbes (1946) was obviously linked with dental sepsis, and allergy as a result of bacterial infection is a well-known phenomenon. Some of the other cases mentioned above also show an allergic possibility. The cases reported as correlated with bacillary dysentery were probably allergic in nature, and in this sense a correlation may be accepted. The whole condition may therefore be considered to be a bacterial sensitization caused by a number of bacteria which may not be allied to one another, and it may be precipitated by one or more attacks by the bacteria.

Pathology and differential diagnosis.—The clinical features make the pathological condition clear. Gonorrhoea is the most important disease to be differentiated. For this, examination of the exudate at various stages of the disease is necessary. With modern technique the consistently negative result for gonococci must be taken to mean that gonococci are absent. With the triad mentioned above present in full and gonococci absent, the diagnosis is Reiter's

disease. The absence of one of the components of the triad may cause difficulty in diagnosis, but the absence of gonococci should settle matters.

A rash with fever and joint pains may be mistaken for secondary syphilis, but syphilis does not cause urethritis, and the WR and the Kahn test will be positive.

The flitting pains in the joints together with fever may remind one of rheumatic fever, but the latter does not cause urethritis. Other conditions to be differentiated are non-specific urethritis, gout, prostatitis of non-gonorrhoeal origin, and the various forms of arthritis and conjunctivitis.

Waelsch (1904) has described a type of illness 'chronic non-gonorrhoeic urethritis of type Waelsch'; in this there is a long incubation period as in Reiter's disease and there are no organisms in the urethral discharge, but there occur posterior urethritis and prostatitis, and Waelsch has not described any hæmatogenous metastatic complication in his cases.

Treatment.—The exact ætiology of the condition being unknown, treatment must necessarily be symptomatic. Miller and McIntyre (1945) feel that good nursing in bed is all that can be done. This view is rather pessimistic, especially in view of the reported success with penicillin by Baxter (1946) and with sulphathiazole by Jackson (1946). Protein shock therapy has been tried by Beiglboeck (1943). One of the cases in the present series was also treated similarly, with apparent success. Fieldsend (1946) used neoarsphenamine in his cases and though he called his cases 'abacterial pyuria presenting as urethritis' it is very probable that at least two of the cases were of Reiter's disease. The response to this arsenic preparation was certain and prompt.

The diet need not be restricted, and as the stay in hospital is very long, some form of diversional therapy is indicated. For the joints the co-operation of a physiotherapist is useful, and if the general health has suffered, ultra-violet radiation is helpful.

The conjunctivitis needs nothing more than a simple eye lotion and the instillation of penicillin is an added adjunct. The keratoderma clears by itself when the general condition improves but it may help the patient to use some form of mild antiseptic to prevent secondary sepsis.

Artificially induced hyperthermia has obviously a field here as evidenced by some of the cases mentioned above. It is best produced by a Kettering hypertherm or a similar appliance.

The secondary anæmia needs no special treatment as it disappears as soon as the main condition improves.

Even if the case is not correctly diagnosed as Reiter's disease, and is treated as gonococcal infection by sulfa drugs or penicillin, nothing but good can result, and as such, and also in view of the reported success with these two drugs,

they should always be tried. Neoarsphenamine is also worthy of trial after these two.

The importance of good nursing is to be stressed, and there should of course be close liaison with the physiotherapist.

The sociological problem connected with venereal diseases comes in here also. It has been categorically stated (Editorial, 1946) that there is no relation between the disease and sexual intercourse; but the view held by Kristjansen (1930) is interesting. He says . . . 'I think that this condition ought to be more discussed owing to its absolute venereal character . . .'. He describes how his case was infected by a girl of 16 who had a yellow vaginal discharge for two years, and who had also caused an uncomplicated non-bacterial purulent urethritis lasting for three months in another man at about the same time. This girl was examined at the local clinic for a period and was found not to have had gonorrhœa. It has therefore to be admitted that Reiter's may be acquired in venery, just as scabies may be, but like scabies it is not a strict venereal disease. But its similarity to a specific venereal disease like gonorrhœa renders it imperative that the condition be remembered whenever a case of clinical gonorrhœa with metastasis fails to show the gonococci.

Conclusion.—The original syndrome described by Reiter has been somewhat enlarged to include keratoderma and few other minor features. Gonococci have never been demonstrated in the exudates and the complement-fixation test has always been negative. Death from the condition has not been reported, and though the condition is long drawn, it is nevertheless self-limited. Treatment is symptomatic and good results have been noted with the use of sulfa drugs, penicillin, and hyperthermia. Though often associated with venery directly or indirectly, it is not a strict VD.

Summary

1. The literature on the subject is reviewed.
2. Four case reports are included.
3. The ætiology is discussed and it is considered that a bacterial sensitization from a variety of infections may cause the condition.
4. The importance of a correct diagnosis is emphasized, as is the essential non-venereal nature of the condition.

TROPICAL EOSINOPHILIA AND SYPHILIS

(A CASE REPORT AND COMMENTARY)

By E. G. H. KOENIGSFELD, M.D. (Berlin)
 CAPTAIN, R.A.M.C.

THE clinical syndrome of tropical eosinophilia, to which the following report presents a contribution, has confronted the medical profession with a number of puzzling difficulties, not the least of which is the impossibility to give a satisfactory definition of the disease.

It has not been practicable so far to classify the syndrome according to aetiological, anatomical or functional principles. All that can be done, for the time being, is to group the various signs and symptoms together and to amalgamate them to a not too clearly circumscribed clinical picture.

The leading sign of the disease is, of course, the striking eosinophilia. It is about the only feature of the syndrome which is absolutely constant, thus constituting the essential factor of the clinical picture. All other signs and symptoms, the asthma, the anatomical changes in the chest, the fever, the high B.S.R., the splenomegaly, the positive serum reactions and even the response to arsenical treatment, are factors which are more or less inconstant, and of which the one or other may be entirely absent in an individual case.

Under such circumstances the definition of the disease remains vague, and the borderline, separating it from other conditions of eosinophilia, necessarily dim, and this state of affairs is not likely to change as long as we have no explicit knowledge as to the causation of the syndrome.

In an attempt to approach the problem with special regard to its aetiology the case reported below was handled in a somewhat unorthodox manner.

Case report

H., a well-nourished Punjabi Hindu of about 50 years of age, was admitted to hospital on 5th October, 1946, with severe dyspnoea and cough, from which he suffered for the past 24 hours.

He was no stranger to this hospital when he was admitted. Already in March of this year he had been treated on account of a similar condition, and was kept under observation for about 5 weeks. At that time he had a moderate leucocytosis, the differential WBC was within normal limits, the eosinophils constituting 2 per cent of the total count.

He was re-admitted to hospital in July 1946 with rather vague complaints of epigastric tenderness for which no definite cause could be elicited in spite of a thorough investigation, which included a barium meal. Unfortunately, no WR or Kahn test was performed on this or the previous occasion.

During the second stay in hospital he had a few catarrhal signs in his chest, but no attack of asthma.

Regarding his previous history he stated that he had been suffering from cough and difficulty in breathing since December 1945; however, he was not very definite about this date and said at times that the trouble had started much earlier.

He had received treatment for malaria in summer 1945. He denied knowledge of any other previous disease. He did not give a history suggestive of previous syphilis: no penile sore or scar was visible. No history of antisyphilitic treatment was elicited.

On examination on 5th October, 1946, he was afebrile, had a pulse of 90 to 100, and was breathless and very distressed. Numerous sibilant rhonchi were scattered all over his chest, there was some flatulence and the abdomen was distended. The tongue was coated, and the pharynx injected. The liver was not enlarged. The spleen, which had been distinctly palpable during his stay in hospital from March to April, could not be felt. He was very restless and excited, and vomited several times.

His condition improved, however, after $\frac{1}{2}$ grain of ephedrine. On 8th October, 1946, a WBC count was done which showed 26,000 cells, the differential count was 36 per cent polynuclears, 32 per cent eosinophils, 18 per cent lymphocytes, 11 per cent mononuclears, 3 per cent smear cells.

The faeces were examined almost daily for ova: the result was always negative although concentration methods were used.

The skiagram of the chest showed a hazy appearance of both lung fields. The lung markings were definitely increased on both sides, and numerous minor peribronchial infiltrations were visible over both middle zones and bases. The apices were comparatively clear.

On 25th October, 1946, the following laboratory examinations were reported: total WBC

20,000, differential count 23 per cent polynuclears, 59 per cent eosinophils, 14.5 lymphocytes, 2.5 mononuclears, 1 per cent basophils.

The sedimentation rate was 3 mm. after the first hour, 9 mm. after the 2nd hour.

Diagram showing the response of a case of tropical eosinophilia with positive Wassermann and Kahn tests to mercury treatment.

(The eosinophil counts of the 2nd and 7th week are not mentioned in the text.)

Blood WR and Kahn—both strongly positive. WR and Kahn in CSF—both negative.

Cell count in the CSF showed 26 WBC per c.mm., predominantly lymphocytes (average of 5 counts, ranging from 20 to 30 WBC).

On the same day, the 25th October, 1946, a specific treatment was commenced, namely inunctions with 33½ per cent mercurial ointment.

On the 27th October, 1946, after 3 inunctions, the patient felt utterly miserable, with severe dyspnoea, a rapid pulse, and a temperature of 101°F.—so far, during the whole course of the disease, he had been afebrile, this being the first and only elevation of temperature while he was under observation.

However, on the following day he felt better, and the temperature was normal again.

On 31st October, 1946, 6 days after the beginning of mercury treatment, he had no asthma, only slight cough and scanty sputum. The latter contained mainly diplococci, pus cells and very little alveolar tissue.

A WBC count on the same day showed 22,600 cells, of which were 40 per cent P., 38 per cent E., 18 per cent L., 2 per cent M., 2 per cent B.

During the following days his condition showed further improvement, and the sputum became more and more scanty. He had very little cough, no asthma and slept well. His appetite became much better.

On 6th November, 1946, his WBC were 14,000 and the differential count 62 per cent P., 10 per cent E., 23 per cent L., 3 per cent M., 2 per cent B.

On the same day, the inunctions were discontinued for the time being owing to a mild stomatitis. Up to then he had been given 12 inunctions of one drachm mercury ointment each.

On 12th November, 1946, i.e. 18 days after commencement and 6 days after discontinuation

of treatment, the total WBC was 11,000, and the differential count 60 per cent P., 6 per cent E., 32 per cent L., 1 per cent M., 1 per cent B.

The blood sedimentation rate was 8 mm. after the first, 23 mm. after the 2nd hour.

His general condition was excellent. He had no cough, no sputum and felt perfectly well.

The inunctions were resumed on the 19th November, 1946, only, when his total white count was normal and the eosinophils numbered 5 per cent, and were continued for 14 days more.

Afterwards he was given 2½ mega-units penicillin. At the end of the treatment another x-ray of the chest was taken which showed a minor degree of bronchitis only.

He was discharged as clinically cured on the 20th December, 1946, with instructions to report in due time for further serological examinations.

Discussion

This case shows so many features, typical for the syndrome of tropical eosinophilia, that the diagnosis appears to be certain beyond doubt.

There are 2 questions, which are likely to arise in this connection, namely:—

(i) Did this patient suffer from syphilis?

Supposing the positive Wassermann and Kahn tests were just unspecific reactions—as most workers seem to presume at present—no changes in the CSF should be expected.

Our patient, however, had a cell count in the CSF of 26, mainly lymphocytes. This, together with the positive serum reactions, is strongly suggestive of syphilis.

The transient fever and deterioration of the patient's condition after the 3rd mercury inunction fit well into this picture. Menon (1946) observed such initial exacerbations with subsequent rapid improvement after arsenical treatment of tropical eosinophilia. In his opinion such a reaction settles practically the diagnosis.

The writer suggests that the temporary increase of the intensity of the process should be interpreted as a Jarisch-Herxheimer reaction, so typical for the response of a number of syphilitic conditions to specific treatment.

(ii) Another question is likely to be asked in this connection: 'Was the tropical eosinophilia in this case connected with the syphilitic infection?'

Weingarten (1943) in his original paper was inclined to think that the syphilis, which he observed in one of his patients, was just an accidental concomitant of the syndrome. He believed that by chance he had discovered that arsenicals—quite apart from their antisyphilitic action—were also a specific remedy for tropical eosinophilia.

As far as one can see, his view has been generally accepted by all later workers and, more important, by all practitioners, who treat the disease with doses of arsenicals quite inadequate for the management of syphilis.

Now, it is extremely improbable that anti-syphilitics, other than arsenicals, should likewise influence tropical eosinophilia, if the latter were entirely unconnected with syphilis.

Out of such considerations this patient was given no arsenicals at all, but was treated by inunctions with mercurial ointment. Penicillin or bismuth were not chosen on account of their much greater therapeutic amplitude. The former was given only after clinical recovery in order to vouchsafe a complete cure.

Following this line of treatment the asthmatic condition subsided within one week, and the eosinophilia was reduced almost to normal within 2 weeks from the beginning of the inunctions. No better results can be expected from treatment with arsenicals.

The conclusion to be drawn from this therapeutic experiment can only be that the disease has apparently something to do with syphilis.

Eosinophilia and asthma point strongly in the direction of an allergic condition. The syndrome in the writer's opinion should therefore be interpreted as an anaphylactic spirochaetosis.

Of course, it cannot be denied that other anaphylactic conditions may evoke the same clinical picture, a possibility which is the more likely as a number of cases fail to respond to arsenicals.

However the writer is unable to accept without reservation the view that the frequent positive Wassermann and Kahn tests in tropical eosinophilia are, as a rule, unspecific. The possibility of syphilis in connection with the syndrome should in no instance be dismissed without careful investigation, of which the testing of the CSF is an essential factor.

Summary

A case of tropical eosinophilia with positive Wassermann and Kahn reactions in the serum and a high cell count in the CSF has been described which responded well to anti-syphilitic treatment other than arsenical.

The view has been expressed that the syndrome known as tropical eosinophilia constitutes—in many instances—a condition connected with syphilis, probably an anaphylactic spirochaetosis.

The writer wishes to express his gratitude to Lieut.-Colonel M. L. Ahuja, M.D., D.P.H., I.M.S., Director of the Pasteur Institute, Coonoor, to Dr. I. G. K. Menon, M.B., B.S., Coonoor, and to Captain J. W. Lovett-Doust, R.A.M.C., for valuable advice and criticism. He acknowledges also his indebtedness to Captain T. A. J. Wickham, I.M.S./I.A.M.C., for his help and keen interest in the preparation of this paper.

[In such cases WR may be positive and Kahn negative. Further, the reaction weakens or disappears with very little anti-syphilitic treatment. This and other recent observations on the disease are not in favour of the author's thesis.—EDITOR, I.M.G.]

PENICILLIN TREATMENT OF EARLY SYPHILIS

By MAJOR BALBIR SINGH, M.D.
Main Hospital, Jamshedpur

SINCE Mahoney and his associates first demonstrated the effect of penicillin on *Treponema pallidum* in experimental syphilis in rabbits and reported the results of a pilot study of the effects of penicillin in four cases of primary syphilis in males, reports of a preliminary nature have been published on this subject by a number of writers. I shall discuss in this report observations on 662 cases of early syphilis that were treated with penicillin in Ceylon Army Command from March 1945 to April 1946.

Material.—It was realized that the material at my disposal was too small for any statistical analysis and that the period of post-treatment observation was not of sufficient length as, owing to the release/repatriation of the majority of the cases it was impossible to carry out a complete follow-up of each case. However I considered that it would be useful to tabulate the observations that were recorded in this one year period.

Table I shows the details of these 662 cases. One hundred and sixty-one showed *Treponema pallidum*; 22 out of these 161 were seronegative. The remaining 501 cases did not show *Treponema pallidum* and were diagnosed on clinical and serological evidence.

Treatment.—Forty thousand Oxford Units of penicillin in 2 c.c. of sterile distilled water were injected intramuscularly every three hours for 7½ days. Serological tests were done before commencing treatment, after it was completed and then at intervals varying from 7 to 90 days.

Table II shows the details of 405 cases treated with penicillin. Some had 0.3 to 1.2 grammes of neoarsenobillon and 0.2 to 6 grammes of bismuth. Others had 4 to 8 grammes of neoarsenobillon and 2 to 4 grammes of bismuth. All cases that were observed for less than 15 days are not included in this table.

Reaction.—Data are available from 292 cases. Two hundred and eighty-two were Indians.

1. Rise of temperature.

	Number of cases	
99°F. to 102°F.	42	14.4%
103°F. to 105°F.	8	2.7%
105°F. and over	6	0.3%

The temperature rose during the first day of treatment and fell down by the end of 24 hours except in one case in which it lasted for three days.

2. Other reactions attributed to penicillin.

(a) Appearance of a rash, not previously present in 2 cases. Rash subsided in two days in one case, and in three days in the other.

(b) Flare up of rash previously present in 1 case.

TABLE I

Nationality		TREATED WITH PENICILLIN ALONE					TREATED WITH PENICILLIN AFTER ADEQUATE OR INADEQUATE TREATMENT WITH ARSENIC AND/OR BISMUTH

(c) Cramps in abdominal muscles in 2 cases. These subsided in 48 hours.

(d) Pain in the joints in 7 cases. It commenced after 2 injections in 4 cases and subsided after 1, 3, 6 and 7 days respectively.

(e) Headache in 4 cases.

(f) Pain in the chest in 2 cases.

(g) Pain in the teeth in 1 case.

(h) Pain in the sore in 1 case.

Pilsbury (1945), Moore *et al.* (1944), Mahoney *et al.* (1943), and Leifer (1945) recorded Herxheimer reactions in 25, 59, 86 and 91 per cent respectively. Only 17.4 per cent of the present series and 29 per cent of the seropositive primary cases showed a rise of temperature. I would not attribute the low percentage of Herxheimer reactions in these cases to any racial difference. The explanation of this probably lies in the paucity of the nursing staff in Field Units. Moreover, most of the Indian patients came from Labour Units; they were intellectually poor, and would not bring to the notice of the nursing staff or the medical officers any reaction unless it was very severe.

Time taken by the lesions to heal.—Chancres in 240 cases healed on the average in 8 to 10 days. Table III shows average number of days

taken in healing according to the stage of the disease when treatment was commenced. Chancres took the maximum time to heal in seronegative primary cases and the minimum time in secondary cases.

TABLE III

Stage of the disease	Number of cases	Average number of days taken for the ulcers to heal
Seronegative primary ..	21	14.2
Seropositive primary ..	179	10.2
Secondary ..	40	8.9

Healing of lesions in the secondary stage :—

1. *Rash.*—Average number of days for the rash to disappear in 47 cases, 11 days.
2. *Secondary syphilides of soles of feet* (one case).—21 days.
3. *Hyperkeratosis of soles of feet* (one case).—30 days.
4. *Mucous patches, tongue* (one case).—14 days.
5. *Ulcer tongue* (one case).—9 days.

* WR was done by Wyler's modification.

6. *Leukoplakia upper lip* (one case).—4 days.

7. *Condyloma and penile warts* (one case with cauterization).—45 days. Two further cases without cautery.—13 and 20 days respectively.

8. *Joint affections*.—3 cases in 26, 10 and 9 days respectively.

9. *Osteoperiostitis* (tibia improved in one case).—12 days.

Serologic response within 1 to 3 days of the completion of penicillin treatment.—Tables IV and V show the changes in the titre of Kahn test and Wassermann reaction when put up within 1 to 3 days of the completion of treatment. Forty-seven and 37 cases showed the provocative effect on Kahn test and Wassermann reaction respectively. This tendency to provocation was most marked in seropositive primary cases that had had no arsenic and/or bismuth before penicillin treatment. Three of 19 seronegative primary cases showed positive Kahn test and two showed positive Wassermann reaction after treatment. Sixty-five cases that had positive Wassermann reaction and negative Kahn test showed positive Kahn test in 12 cases after treatment. The titre of Kahn units showed more tendency to reduction by the end of penicillin treatment than the changes in the Wassermann reaction. 54.5 per cent of the cases who had positive Kahn test before treatment showed definite reduction in the Kahn titre but

the Wassermann reaction of the same cases showed similar changes in 30 per cent only. The technique used for Wassermann reaction has very limited scope for the determination of the titre of the reagin but it is definitely obvious from the fact that 33 (18.7 per cent) out of 176 cases who showed 4 or more Kahn units before treatment became negative after treatment and only 13 (8.5 per cent) cases out of 152 who had Wassermann reaction ++ became negative.

Sixteen cases had a titre of 1, 2 or 3 Kahn units before treatment. Ten showed provocative effect and only one became negative after treatment.

TABLE VI

++ = 3 doses and 5 doses of complement fixed.

+ ± = 3 doses fixed, 5 doses partially fixed.

+ = 3 doses fixed, 5 doses not fixed.

± = Partial fixation of 3 doses, 5 doses not fixed.

TABLE VII

Complete seroreversal Kahn tests

Stage of disease	Number of cases	Average interval in days	Complete reversal in number of days
Seropositive primary	31	19.0	47.8
Seropositive primary, treated with arsenic and/or bismuth before penicillin treatment.	28	16.0	23.5
Secondary syphilis ..	14	42.0	92.0
Secondary syphilis, treated with arsenic and/or bismuth before penicillin.	14	40.0	76.0

Tables VI and VII show the average number of days taken for complete seroreversal in different stages of the disease in 99 cases. All cases whose blood was examined at longer intervals are not included in these tables.

Complete seroreversal was quicker in both the seropositive primary and the secondary stage when penicillin was administered after a few or

more injections of arsenic and/or bismuth. The tendency to become negative was more marked in Kahn tests when these were done at the end of penicillin treatment as shown in table IV, but final seroreversal to negative was much quicker in Wassermann reaction than in Kahn tests especially in seropositive primary syphilis.

Mahoney *et al.* recorded 70 days as average number of days for seroreversal. Leifer recorded that the majority of his cases showed seroreversal in 120 days. The writer observed this taking place in 48 and 92 days in seropositive primary and secondary syphilis respectively. Two hundred and two days was the highest number of days for seroreversal in seropositive primary and secondary syphilis. Nine out of 55 cases that were included in tables VI and VII showed reversal in less than 20 days. Sometimes the Wassermann reaction became ± and the Kahn test remained negative. The writer does not consider these to be relapses as after this fluctuation from negative to doubtful and back to negative, they showed a stationary negative when tests were repeated.

Late effect of treatment.—Seronegative primary syphilis.

Table VIII shows the results of the last test in 22 cases of seronegative primary syphilis. Twenty were negative, one showed a weakly positive Wassermann reaction. (Wassermann

reaction \pm^*) on the 29th day and the other 2 Kahn units on the 37th day. There were four cases in this group who showed provocative effect on Wassermann reaction and Kahn test after penicillin treatment. Two became negative within one month and the other two, who had weak positive Wassermann reaction and Kahn tests on the last test, were likely to become

arseno-bismuth therapy. Twenty-one per cent of these 99 and 28 per cent of those treated with penicillin only were seropositive on their last test.

Table X shows the serologic response of 120 cases of secondary syphilis, 44.2 per cent were seronegative on their last test. The proportion of negative to positive was largest in the group

TABLE VIII

Serologic response and relapses in seronegative primary syphilis

Period of observation (days)	Number of cases	WR ++ and Kahn units 4 or more	WR + or \pm and Kahn units 4 or more	WR negative and Kahn units 4 or more	WR ++ or + and Kahn units 3, 2, 1 or nil	Total number of cases with positive WR and Kahn tests	WR \pm and Kahn units 3, 2 or 1	WR \pm and Kahn units nil	WR negative and Kahn units 3, 2 or 1	Total number of cases with weak positive or doubtful result	WR and Kahn negative	Serologic relapses

TOTAL ..	22	1 (4.5%)	1 (4.5%)	2 (9.1%)	20 (90.9%)	Nil

negative if they had been observed longer. There were no relapses in this group.

Table IX shows serologic response of 264 cases of seropositive primary syphilis. 58.5 per cent were seronegative at their last test. The proportion of negatives to positives was largest in the group that was observed for 75 to 150 days. 25.3 per cent were seropositive and 12.8 per cent showed weak positive or doubtful results. There were nine relapses which I will discuss later.

I shall not go into the details of the seropositive cases that were observed for less than 75 days. Thirty-nine cases were observed for more than 75 days. Eighteen cases showed weak positive Wassermann reaction and/or Kahn units 3, 2 or 1 on their last test, two of these 18 were fluctuating from negative to doubtful and back to negative; 22 out of these 39 had Wassermann reaction and Kahn tests positive on their last test; 18 had already shown reduction in the titre of Kahn or Wassermann. Four, who showed no changes, were observed for 80, 159, 184 and 320 days.

Table IX includes (i) 19 cases who were observed for 9 to 14 months. There were 4 seropositive cases in this group. Three had already shown reduction in the titre and one showed no change. There was one relapse in this group. (ii) 99 cases of seropositive primary syphilis who were treated with penicillin after they had

that was observed up to 270 days. 18.3 per cent showed weak positive or doubtful results. There were 5 relapses which will be discussed later.

Cases that were observed for less than 75 days will not be discussed. Twenty-five cases were observed for more than 75 days. Ten out of 12 cases had Wassermann reaction and/or Kahn test positives, and of these 11 had already shown reduction in the titre of Kahn units and/or a similar change in the Wassermann. Two cases that showed no change in Wassermann and/or Kahn were observed for 76 and 96 days respectively. The remaining 13 of the 25 cases showed weak positive or doubtful results on their last test. All these had shown reduction in the titre of both Wassermann reaction and Kahn tests and were likely to become negative if they had been observed over a longer period.

Table XI shows 14 (3.4 per cent) serologic relapses in 405 cases. There were 3 relapses amongst 138 British cases and 11 amongst 524 Indians and Ceylonese. If all cases that were observed for less than 113 days are excluded (the minimum period during which a serologic relapse was observed), the incidence of relapse was 8.3 per cent. There were no relapses in seronegative primary; seropositive primary showed 9 (3.4 per cent) in 264 cases, and secondary syphilis showed 5 (4.1 per cent) in 120 cases. Incidence of relapses in seropositive primary syphilis would have been less than 3.4 per cent but for the fact that 4 out

*The correct designation of such a reaction is 'doubtful'.—EDITOR, I.M.G.

*Refer to table V for interpretation of results of cerebrospinal fluids.

of 9 cases that relapsed were diagnosed as syphilis in the 6th, 7th or 8th months of 1944. They were put on arseno-bismuth therapy but it was stopped as two of them developed toxic jaundice, one had dermatitis, and the fourth one did not turn up for treatment. They were put on penicillin, 7, 4, 7 and 11 months respectively after arseno-bismuth therapy was stopped.

Clinical and concomitant serologic relapses were observed in 4 out of these 14 cases. Two out of the remaining 10 serologic relapses showed a chancre redux and one had an ulcer on the prepuce; in none of these cases was *Treponema pallidum* demonstrated. Inguinal glands were enlarged however, and there was no history of fresh exposure. Four of the remaining 7 cases were not observed after the serologic relapse was detected as they were either released or transferred from Ceylon Command; venereal cards of the other three cases showed no record of clinical relapse though they had reported for serologic tests on one or more occasions after the serologic relapse was detected. If the possibility of reinfection in the above-mentioned 2 cases with chancre redux was not considered the clinical and concomitant serologic relapse rate was 6 (1.4 per cent) in 404 cases, and excluding all cases that were observed less than 113 days it came to 6 (3.5 per cent) in 168 cases. The relapse rate for seropositive primary and secondary syphilis on the same basis was 4 (3.3 per cent) in 119 and 2 (5.0 per cent) in 41 cases respectively.

The cerebrospinal fluid was tested in 7 cases. The Wassermann test was negative in 6 cases and 1 (no. 8093 in table XI) showed partial

	Number	Per cent
WR of blood and the CSF negative .. Number of cells per c.mm. varied from 0-5 in all cases except two who showed 7 and 8 cells respectively. Protein content varied from 20-40 mg. except in one case who had 60 mg.	39	75.0
WR of blood positive and the CSF negative Five out of these 8 cases were serologic relapses and three out of these five were clinical relapses as well.	8	15.4
WR of blood negative and the CSF positive ..	5	9.6
WR of blood and the CSF positive ..	6	11.5
Result of WR of blood not known and the CSF positive ..	2	3.8

Twelve out of 52 cerebrospinal fluids were from the British personnel and only 2 had a positive Wassermann amongst this group.

There was partial or complete fixation of 3 doses of complement with 1 in 5* dilution of the cerebrospinal fluid in 4 cases, with 1 in 2.5 dilution in 4 cases and with 1 volume of undiluted fluid in 5 cases.

Ten out of 13 cases with positive Wassermann of the spinal fluids were seropositive primary syphilis and the remaining three were cases of secondary syphilis. Relatively higher incidence of the positive spinal fluids in seropositive primary syphilis could be explained by the fact that 5 out of these 10 were not fresh cases. Four of them had irregular treatment with arseno-bismuth therapy which was stopped for 4,

TABLE XII

Wassermann reaction of cerebrospinal fluid after 6 months or later

fixation of three doses of the complement in 1 in 2.5 dilution. None showed increase in the cells. Protein was 25 to 30 mg. per 100 c.c. except in one case who had a negative Wassermann and 45 mg. of protein.

Table XII shows results of the Wassermann reaction of 52 cases whose cerebrospinal fluid was tested six months or later after penicillin treatment.

3, 11 and 18 months respectively before they were put on penicillin. The fifth one gave no history of primary lesion and was admitted with positive Wassermann and Kahn tests. Incidence of a symptomatic neuro-syphilis, 13 (25 per cent) in

* A 1 in 5 dilution of CSF for a WR is rather weak. Wyler recommends a series of 1 in 5, 1 in 2, undiluted CSF, and 2 volumes of undiluted CSF. Greval employs only the last two strengths.—Editor, I.M.G.,

52 cases, was obviously higher than the figures quoted by some of the well-known authorities. This was very probably due to lack of sufficient information in the clinical records that were at our disposal.

Summary

1. *Material*.—The case cards of 662 cases of syphilis who were treated with penicillin were reviewed. A large number of cases was not considered in preparing the tables in the preceding pages as the relevant information was not available.

2. *Reaction*.—(a) Rise of temperature occurred during the first day of treatment in 17.4 per cent of the cases; it rose above 103°F. in 9 cases only and came down by the end of 24 hours in all except one case in whom it lasted for three days.

(b) Cutaneous reaction and pain in the joints and muscles were also observed in a few cases.

Reaction was never so severe that treatment had to be stopped.

3. *Healing of the lesions*.—Primary lesions healed in 8 to 10 days. Rash healed in 11 days on the average.

4. *Results of Wassermann and Kahn tests within 1 to 3 days of the completion of penicillin treatment*.—Provocative rise of titre of Kahn units occurred in 47 cases out of 256. Similar provocation was also observed in the Wassermann reaction in 37 out of 270 cases. Provocation was most marked in seropositive primary syphilis if they were not put on arsenic and/or bismuth before penicillin treatment. The titre of Kahn units showed reduction in 54.5 per cent. Similar change in Wassermann was shown by 30 per cent only.

5. *Seroreversal*.—Final seroreversal was quicker in Wassermann than in the Kahn unlike the initial effect as mentioned in para 4 above. Seroreversal was quicker in those cases of seropositive primary syphilis who were switched on to penicillin after they had 1 to 6 injections of arsenic and/or bismuth. Seroreversal took longest time in secondary syphilis.

6. *Late effects*.—Seronegative primary cases had the most favourable response. 90.9 per cent were seronegative on their last test. Seropositive primary and secondary syphilis showed 58.5 per cent and 44.2 per cent respectively as seronegative on their last test.

7. *Relapses*.—No relapses occurred in seronegative primary syphilis. Serologic relapse rate was 3.4 per cent in seropositive primary syphilis and 4.1 per cent in secondary syphilis. If the incidence is calculated by excluding all cases observed for less than 113 days (the minimum period during which a serologic relapse was observed), the serologic relapse rate came to 8.3 per cent. Serologic and concomitant clinical relapses were 3.5 per cent on the same basis.

8. *Cerebrospinal fluid*.—Fifty-two cases were tested six months or later after penicillin treatment. The fluid was positive in 13 cases.

Serum and spinal fluid were positive in 6 (11.5 per cent) cases.

9. The probable explanation for the relatively higher incidence of serologic relapses and of positive cerebrospinal fluid in seropositive primary cases was the inclusion in this group of a few cases who were not fresh cases of seropositive primary syphilis. They were put on penicillin after they had irregular treatment with arsenic and/or bismuth.

10. Incidence of relapses as mentioned above was lower than the rate recorded by some well-known authorities with arseno-bismuth therapy. This, however, should not necessarily convey that penicillin was superior to arsenic and/or bismuth. The relapse rate is sure to go up with the lapse of time and it will be long before it will be possible to assess the effect of penicillin treatment in early syphilis.

I take this opportunity to express my gratitude to the personnel of 24 Indian Field Laboratory, to the Medical Officers and Specialists in Venereology whose Clinical records were so readily made available to me, to Major M. G. Sharma, I.A.M.C., to Brigadier C. A. Slaughter, R.A.M.C., D.D.M.S., Ceylon Army Command, to Lieut.-Colonels J. Reidy, A. C. Bhatara and R. M. Hector, R.A.M.C., and to Major S. C. Banerji, the Adviser in Venereology, GHQ(I).

PENICILLIN THERAPY IN CHAN-CROIDAL BUBO

By K. D. LAHIRI, M.B., B.S.

Senior Hony. Medical Officer, Skin and V. D. Dept., Patna Medical College Hospital

In the literature one hardly finds the use of penicillin in the treatment of infection with *Hæmophilus ducreyji*. Nair (1945) did not find any action of penicillin on chaneroid. Prebble (1946) observed no improvement in soft sore with penicillin therapy but he advocated local application of weak penicillin solution to promote healing in chaneroid which is supposed to act by clearing the secondary infection. The present writer (1945a) reported on the routine use of penicillin in treating chaneroid and has since been using it with very encouraging result in buboes due to *H. ducreyji* infection. He (1945b) advocated injection of penicillin in the bubo every three hours. He (1946a) strongly advocated penicillin therapy particularly in multiple infection of venereal origin. He (1946b) has treated bubo with and without phagedena with penicillin alone successfully. In complications of chaneroid, like a threatened bubo, he (1947) found better result by continuing the penicillin injections in doses of 0.02 M.U. every three hours into the bubo along with

intramuscular injections of penicillin or alone. For sulphonamide intolerant cases of chancroid penicillin has been advocated by Strakosch and his co-workers (1945) and Day (1946).

Recently the author has observed a large number of cases of bubo, some with pudendal sores, caused by Ducrey's bacillus as shown by positive Ito-Reinstierha's intradermal antigenic test and negative dark-field and W.R. test.

Discussion

Successful penicillin therapy in chancroidal buboes depend principally on the susceptibility of the infecting organisms (*Haemophilus ducrey*) and on an adequate concentration of penicillin in the blood. Studies of *H. ducrey* *in vitro* have shown the activity of penicillin against this infection (Mortara *et al.*, 1944). Meads and his associates (1945) have observed that the only other gram-negative bacillus which is sensitive to penicillin is *H. ducrey*.

A dose of 0.05 M.U. of penicillin intramuscularly every 2 to 3 hours together with two to three injections of penicillin (0.005 M.U.) in the bubo every 6 to 8 hours and orally sulpha drug (sulphadiazine and sulphathiazole each 0.25 gm.) every 4 hours for a period of 48 hours cures an ordinary case of chancroidal bubo. In the earliest sign of buboes when the inguinal gland has not been appreciably enlarged in size but there is only pain on walking and tenderness to touch penicillin therapy has aborted the bubo in a lot of cases in 24 hours. In an advanced case the dose of penicillin-sulpha-drugs are prolonged for 72 hours. The same dose of penicillin sulphonamide is helpful in bubo with chancroidal sore (Lahiri, 1946c).

Follow-up of every case of chancroidal bubo by serological examination every three months for a period of 2 years is essential to eliminate asymptomatic latent syphilis.

Conclusion

Every case of bubo should be treated with penicillin-sulpha-drug therapy.

Acknowledgment

My thanks are due to Dr. Nawab and Major Sinha for their encouragement and discussion with penicillin therapy in venereal diseases.

CUTANEOUS GUMMATA OF FACE

By K. D. LAHIRI, M.B., B.S.

Honorary Senior Medical Officer, Skin and V. D. Department, Patna Medical College Hospital, Bihar

WHEN syphilis is not treated in the early stage the patient tries to establish a balance between the body's defence and the *T. pallidum*. Thus a state of latency occurs when the number of organisms get reduced and the tissue reaction of the patient also is somewhat changed. Eventually a state of *allergy* is established. This allergy is responsible for the infiltration of the tissue with lymphocytes, plasma cells and epithelioid cells and also obliterative endarteritis of the small vessels, resulting in the reduction of the blood supply and ultimate necrosis. Any part of the body may be affected by syphilis and the present paper deals with cutaneous gummata of face.

Occurrence after infection of the condition is very variable and may be at any time of the patient's life, and is usually from 3 to 5 years after infection in India.

Types are mainly of two different types, such as (1) nodular and (2) nodulo-ulcerative types.

Spread.—In late syphilis the spread is generally centrifugal. The new nodules always form outside the circle and heals up at the centre with parchment-like scar. There is sometimes pigmentation. The lesion is polymorphic in character.

Early syphilitic lesions of the face like extra-genital chancres on lips, nares and other places on the face are rare in India and have been estimated to be only 10 per cent of all cases of extra-genital chancres (Lahiri, 1945a).

Late syphilitic lesions of the face are quite common in India and form about 27 per cent of all cases of late syphilitic lesions of the body (Lahiri, 1945b).

The nodular syphilitic rash on face (figure 1, plate XXII) is quite common and the patients are not infrequently treated as sycosis barbæ by mistake. The hyperkeratotic rash of secondary syphilis or as it is now called nodular late recurrence on face (figure 2, plate XXII) is also seen in India and is generally stamped as due to *B. hansenii* due to the resemblance to leonine face of leprosy. There may be a solitary gumma of the lip which is quite common in India and has a characteristic indolent induration which seldom escapes notice and is hardly mistaken. Sometimes multiple nodular gummata are found on the face. Some of these nodules go on to ulceration. These ulcers when coalescing give rise to the picture of lupus vulgaris of face. In some cases the nose may be destroyed and the nares may be closed and the lips may be destroyed and united, leaving only a hole of about 1/10th inch in diameter (figure 3, plate XXII). In another type which is very common there is destruction of the skin on the bridge of the nose together with destruction of the underlying bones (figure 4, plate XXII). These are the common cases in every hospital in India. A very rare type of cutaneous gummata of the face that has been observed is associated with the rhino-pharyngitis mutilans called gangosa (figures 1 to 5, plate XXI, I.M.G., September, 1947).

Observation.—All these five cases had history of ulcer penis following on sexual contact; positive serology (WR and Kahn). Levaditi's stain in biopsy from case 5 did not show *T. pertenue* and skiagram showing destruction of the nasal septum, palate and parts of maxilla (skiagram, lateral and P-A views) with evidence of rarefaction and new bone formation at the lower end of tibia (skiagram, lateral and P-A views of the right leg). Cases 1 and 2 were treated both with heavy metals and also with penicillin with very good results (Lahiri, 1947). Case 3 was treated in the surgical department from where it was referred and the rest were treated with heavy metals but the case of gangosa never came for plastic operation after the routine heavy metal therapy.

Conclusion.—It has yet to be found out why syphilis produces destruction and mutilation of the face in a particular individual. Besides free compulsory treatment for every syphilitic in India, a very well-organized India-wide anti-V.D. drive should be instituted to save the millions in India from crippling, blindness, dumbness, infant mortality and unhappiness.

Acknowledgment

I am thankful to the Superintendent for his permission to publish this paper and to Major Sinha, Dr. Nawab, Dr. Mehrotra, and Professor Prasad of the Patna Medical College Hospital for help.

A STUDY IN THE PREVALENCE OF VENEREAL DISEASE IN INDIA JUDGED FROM A SERIES OF ROUTINE KAHN TESTS AND FROM HISTORIES IN SANATORIUM PATIENTS

By R. M. BARTON, M.A. (Oxon.)

and

A. V. OOMMEN, B.Sc. (Madras)

(From the Laboratory, U. M. T. Sanatorium, Arogyavaram, Madanapalle)

MANY statements are seen as to the prevalence of venereal disease in India, some based on the number of such patients attending dispensaries or admitted to hospital wards, but most of them on general impressions based on little scientific evidence. It was thought that a contribution to our knowledge might be made by a study of a large series of routine examinations on patients who have come to the sanatorium at Arogyavaram, Madanapalle, all of whom were suffering from or suspected to be suffering from tuberculosis, and none of whom came because they thought they were suffering from venereal disease.

Material

The study originally included 8,211 patients admitted from June 1927 when the senior writer introduced the Kahn test at Arogyavaram until 30th June, 1947, but this number was subsequently reduced to 7,221. The reason for this was that the study showed that there was an unusually high number of weak reactions in the Kahn test carried out from 1927 to 1929; during this period a locally made antigen was used, and when a commercially prepared antigen was

employed about 1930 the number of weak reactions dropped abruptly and has since remained constant. We consider it therefore right to omit the 862 patients from the earlier years from our study and confine ourselves to the patients admitted since 1930. A further 128 patients were omitted either because they were re-admitted during the same year or because their stay was too short for a proper examination to be made as they left the day of admission or the following day.

In addition to patients in the sanatorium we have included a series of routine Kahn tests done on children and young adults in school hostels in the Chittoor and North Arcot districts of the Madras Presidency.

In the study of the patients the Cope Chat card system was used, and the details taken from the patients' clinical records included sex, age, marital status, community, province, occupation, diagnosis of tuberculous or non-tuberculous disease, and the history with regard to venereal disease given by patients on admission.

Of the 7,221 patients studied, the Kahn test was done in 6,324 and was not done in 897, many of these being patients who had been previously admitted and who returned for a check-up or were re-admitted and the Kahn test was not repeated. There was no selection of cases omitted and they occur in all groups and classifications studied. The percentage of omitted Kahn has gradually been reduced until in 1947 it has been only 2.5 per cent.

The antigen used for the tests has been Messrs. Parke Davis' Kahn standard antigen except for a very short period during the war when 10 c.c. of an antigen made in India was used. This local antigen was satisfactory but a second batch from the same place had to be discarded as it gave precipitation in all titrations tried. The Parke Davis antigen seemed good throughout the whole period.

General results of Kahn test

The general results of the Kahn test are shown in table I. The figures are grouped in 5-year

TABLE I
General results of Kahn reaction

Kahn reading ..	1930-34	1935-39	1940-44	1945-47	Total

++ ..	45	59	32	34	170
+++ ..	23	28	33	16	100
++++ ..	30	46	48	24	148
	6.8%				6.6%
Total ..	1,433	1,787	2,010	1,094	6,324
No Kahn ..	310	277	220	90	897
Total patients ..	1,743	2,064	2,230	1,184	7,221

periods in order to show if there is any change in the general results since 1930; the Kahn readings are the usually accepted readings based on the average of the 3 tubes. The percentage has been calculated for the definitely positive readings, but not for the minor reactions although in some cases these may be of significance.

It will be seen from table I of the 6,324 patients that the percentage of positives was 6.6 for the whole period, and that there is little variation in the different 5-year periods, the highest being 7.4 per cent in the 1935 to 1939 period and the lowest 5.6 per cent in the 1940 to 1944 period. The question arose whether this difference was of any significance, and in an examination of the percentages in the various years the following was found:

TABLE II

Year	Per-centage of positives	Year	Per-centage of positives	Year	Per-centage of positives
1935	7.1	1940	4.3	1945	6.3
1936	10.5	1941	4.8	1946	7.8
1937	7.3	1942	5.8	1947 (†)	5.6
1938	7.0	1943	6.2
1939	5.5	1944	6.7

Table II shows a gradually decreasing percentage of positives during the pre-war years with its lowest in the first war year. Thereafter there is a gradual rise. Does this reflect a real change in the general infection rate during the war? Admittedly the figures for the tests in each year are small, varying from 331 to 447, but the question is prompted by the smoothness of the curve if the percentage were put in a graph form.

Sex

In order to examine if there is any difference in the figures for men and women, the results are analysed as in table III.

From table III it will be seen that the average Kahn positive for males is 7.1 and for females 5.3, and except for one year in the 1935-39 group the difference is fairly constant and the percentages for females show the usual small variations from year to year which would be expected. In 1936 out of 108 women 17 gave a positive Kahn (15.7 per cent), the only year in which the percentage of positives for women was higher than that for men. This unexpectedly high number, admittedly in a small series, influenced the figures for the whole 5-year group. When an examination was made of the figures for the individual years from 1935 no smooth curve was found for either men or women separately as was found for both together, although for both sexes the lowest figure was reached in 1940, 5.2 per cent for men and 2.5 per cent for women.

TABLE III
Sex and Kahn reaction

Kahn reading	1930-34		1935-39		1940-44		1945-47		Total	
	Male		Male		Male		Male		Male	
	No.	%	No.	%	No.	%	No.	%	No.	%
Negative	804	..	1,074	..	1,222	..	682	..	3,782	..
+	80	..	61	..	59	..	33	..	233	..
++	53	..	42	..	54	..	31	..	180	..

+++++	25	5.2	28	7.6	40	6.3	20	7.8	113	7.1
Total	1,013	..	1,271	..	1,425	..	809	..	4,518	..
Female			Female		Female		Female		Female	
No.			No.		No.		No.		No.	
347			438		519		250		1,554	
38			30		28		11		107	
13			17		15		13		50	
13			9		5		6		41	
4			4		10		1		19	
5			18		8		4		35	
420			516		585		285		1,806	
Total			Total		Total		Total		Total	
1,013			1,271		1,425		809		4,518	

The curve is therefore probably of little or no significance.

Age

The Kahn results were then considered according to age, and for this purpose those below 15, that is, in general below puberty, were taken as one group, from 15 to 19 years as another group, and thereafter groups of 10 years. In the group of 50 years and above are included 17 men and 2 women of 60 years of age or more. As the examination of the 5-year periods has shown that there is not much change in the different periods this grouping has been dropped for subsequent analyses, specially as the subdivisions would become very small and percentages of little value. The results for the age groups for the whole series are given in table IV.

It will be seen from table IV that in the small series of pre-puberty patients the positives are very low, 3.4 per cent for boys and 1.7 per cent for girls, with an average of about 2.5 per cent. As no special examinations were made for marks of hereditary syphilis, it is not possible to say at this stage whether this percentage indicates an inherited infection. The same low figure is found in the 15 to 19 year female group, namely, 2.0 per cent, but the male percentage has increased to 6.8 per cent. From 20 to 39 years of age the positives for the two sexes are about equal, the percentages in the 30-year group being higher than in the 20-year group, and from 40 years of age onwards the percentages for males are higher than those for females.

Marital status

The Kahn reaction in relation to marital status is shown in table V.

From table V it will be seen that the positive Kahn percentage for unmarried women remains low, namely, 2.7 per cent, but slightly higher than the average (2.0 per cent) for the age groups up to 20 years of age in which the majority of unmarried women fall. That for unmarried men is 6 per cent, just a little below the percentage for all males under 20 years of age which would work out at 6.4 per cent. Both sexes have a higher positive percentage in the widowed state, for men 14.4 per cent and for women 11.1 per cent, but the figures are not large.

Community

In order to see if there was any variation in the Kahn positive percentages in the different communities, the figures were analysed according to community as shown in table VI. The divisions made were Hindus, Muslims, Indian Christians, Anglo-Indians, Europeans and others, this last group including Burmans, Chinese, Sinhalese and a few Armenians and Asiatic Jews. Some Indians whose domicile was not normally in India were included in their community group.

From table VI it will be seen that there is little difference in Hindus, Muslims and Indian

Total ..	1,806	563	2,615	1,162	97	81

Christians, the figures for Muslims being slightly higher than the others. The European group has lower figures, only 3 men and 1 woman being found positive of 162 patients. The men in 'Others' show 12.0 per cent positive, the highest figure in all the groups.

Province

The figures analysed according to the domicile of the patients are shown in table VII. As was to be expected from the situation of the sanatorium, the majority of patients came from Madras Presidency, 54 per cent, the next largest series was from the Indian States, mostly the South Indian States of Travancore, Cochin, Mysore and Hyderabad. As the numbers proved to be small from the North and Central Indian Provinces, except Bengal, they have been grouped together. Non-Indian domicile was mostly Ceylon, Burma and Federated Malaya States.

given by the patient and where there were large groups figures are given separately even though some of these might be of the same general social status as some of the general groups. Of course, occupation is not a reliable guide to social status as 'students' include patients from all social ranks, and a 'merchant' may vary from a petty shopkeeper to a merchant prince. Occupations with smaller numbers are grouped, such as artisans which includes many trades requiring some technical knowledge below administrative rank. Professional classes include lawyers, businessmen, Government servants of gazetted rank, missionaries and many others and in this group we also include the smaller group of 'upper' classes, zemindars and others. If a woman had no occupation of her own, she is classified under that of her husband or guardian.

From table VIII it will be seen that the highest percentages of positives were found in

TABLE VII
Provinces and the Kahn reaction

Kahn reading	Madras	Bombay	Bengal	Indian States	Other Provinces	Non-Indian	Total
Negative ..	2,829	115	643	1,239	242	268	5,336
+ ..	179	7	41	87	14	12	340
± ..	134	4	25	57	5	5	230
++ ..	104	2	16	36	2	10	170
+++ ..	59	1	14	14	4	8	100
++++ ..	101	2	10	26	1	8	148
Total ..	3,406	131	749	1,459	268	311	6,327

The positives for Madras are slightly higher than all the other figures except the non-Indian domicile and this last group includes the high figure for non-Indians. The figure for North and Central India and Bombay are low, namely, 2.7 per cent and 3.8 per cent.

Occupation

The Kahn reaction and occupation which also give some indication of social status have been studied in table VIII. 'Occupation' was that

the police, namely, 16.3 per cent, the next highest in the artisan group, 11.6 per cent, and cultivators, landlords, servants and coolies were all above the general average of 6.6 per cent. The lowest figure was for doctors and nurses, but whether this is due to less infection or facilities for diagnosis and treatment if infection has been incurred, cannot be ascertained. The figure for students, namely, 4.4 per cent, is low and perhaps is to be explained by the age of the group mostly below 20 and also that in the group are included

a considerable number of unmarried girls and young women (see tables IV and V).

Tuberculosis and other diseases

The Kahn results were next analysed in relation to the tuberculosis or other diseases from which the patients were suffering (see table IX). The groups taken were pulmonary tuberculosis (sputum positive and sputum negative); non-pulmonary tuberculosis; other pulmonary diseases such as bronchitis, asthma, lung abscess, bronchiectasis, non-tuberculous pneumonia and non-tuberculous pleurisy, tropical eosinophilia; other diseases which included heart disease, malaria, and a miscellaneous group in which the diagnosis was syphilis, malignant disease or other disease; and a group in which no active tuberculosis or other disease was found.

elicit and therefore the figures given in the analysis in no way are claimed to represent the real position. Even where a history of venereal disease was given, it was only rarely supported by information as to any misconception or serological examinations; so the possibility of mistake is not excluded. Histories such as 'doubtful' and swelling of the inguinal glands are classified as 'doubtful'. In women a history of repeated abortions, miscarriages and early infant deaths have been classified under 'doubtful', but one or two abortions or miscarriages have been ignored. Only two women in the whole series gave a history of venereal disease, namely gonorrhœa. This investigation is shown in table X, where 897 patients who had no Kahn test have also been included, making a total of 7,221 patients.

Total ..	4,788	606	185	50	104	141	14	13	47	377				

The sputum plus cases show a Kahn positive rate of 6.7 per cent. The highest percentage, namely 15.6 per cent, was found in the tropical eosinophilia; 14.3 per cent was found in the small group of non-tuberculous pneumonia and pleurisy. Only 2 per cent Kahn positive was found in the bronchitis, asthma, lung abscess and bronchiectasis group. Low figures 2.1 per cent were also found in the group with no active disease. The number of positives in the miscellaneous group, 17 out of 49, is high because the final diagnosis of the disease producing the symptoms for which the patient came for treatment was syphilis in 16.

History of venereal disease

On admission of the patient a medical history is taken by the doctor on duty. The guiding notes on the case sheet include venereal disease, but it is probable that in a great many cases no questions were asked about venereal disease, and in this study, absence of any information in the history is taken as no history. A history of venereal disease is often notoriously difficult to

Table X shows that of the total number of patients 1.2 per cent gave a history of syphilis only, 0.7 per cent of syphilis and gonorrhœa and 2.5 per cent of gonorrhœa only, a total of 4.4 per cent. A doubtful history was given in 0.9 per cent, 0.6 per cent accounted for by repeated abortions and 0.3 per cent for other reasons. Of 130 patients who gave a history of syphilis, with or without gonorrhœa, 44 or 33.8 per cent gave a positive Kahn and 12.3 per cent with minor reactions; of 157 patients who gave a history of gonorrhœa, 23 or 14.7 per cent gave a positive Kahn and 21 or 13.4 per cent a doubtful Kahn. Of 38 patients with a history of repeated abortions, 8 gave a positive Kahn as did 7 of 21 other patients with a doubtful venereal history. Looking at the figures in another way, of 418 patients with a positive Kahn, 44 or 10.8 per cent gave a history of syphilis and 23 or 5.5 per cent of gonorrhœa alone. Of 5,336 patients with a negative Kahn, 70 or 1.3 per cent gave a history of syphilis. Of 5,974 patients with no history of venereal disease, 336 or 5.6 per cent had positive Kahn and 523 or 8.8 per cent doubtful Kahn.

TABLE X
History of venereal diseases and Kahn reaction

Kahn reading	Syphilis	Gonorrhoea	Abortions, etc.	Doubtful	No venereal disease	Total
Negative	70 (30)*	113	21	13	5,119	5,336
±	6 (2)	5	4	1	324	340
+	10 (3)	16	5	0	199	230
++	14 (3)	6	2	4	144	170
+++	16 (3)	6	2	1	75	100
++++	14 (8)	11	4	2	117	148
Total with Kahn test ..	130 (49)	157	38	21	5,974	6,324
No Kahns	8	23	4	1	861	897
Total patients	138	180	42	22	6,835	7,221
Percentage of all patients ..	1.9	2.5	0.6	0.3	94.7	100

*The figures in brackets indicate the number of patients with a history of both syphilis and gonorrhoea.

Repeated Kahn tests

In order to check a positive Kahn or even a negative sometimes, the test was repeated in a number of patients. Also in a considerable number of positive patients treatment was instituted without a further check although frequently a Kahn test was done during the course of treatment. Only one repeated Kahn test for a patient is shown in the table even if several were subsequently done. The results of the repeated Kahn are shown in table XI.

6 became +++++, 4 became ++ without treatment; of 63 +++++ Kahn, 4 became +++ without treatment. None of the +++ and +++++ Kahn became negative or doubtful without treatment.

Routine Kahn tests in school children

As mentioned earlier a series of routine Kahn tests were done on children in school hostels mostly Christians in certain schools and training schools in the Chittoor and North Arcot

TABLE XI
Repeated Kahn tests compared with original test

Original Kahn reading	REPEATED READING												Total
	Same	Negative		±		+		++		+++		++++	
		Treatment	No treatment	Treatment	No treatment	Treatment	No treatment	Treatment	No treatment	Treatment	No treatment		
Negative ..	94	1	3	98
± ..	4	..	8	1	..	13
+ ..	1	..	8	3	1	13
++ ..	7	3	5	..	1	1	4	..	3	..	4	..	26
+++ ..	8	8	..	6	..	3	..	2	4	6	34
++++ ..	27	3	..	7	..	3	..	8	..	11	4	..	63

From table XI it will be seen that of 98 negatives retested, 3 gave a ++ positive and one a ±. Of 13 ± tests, 8 were negative on retesting and one +++. Of 13 + tests, 8 became negative, 3 ++ and 1 ++++ on retesting. Of 26 ++ tests, 5 were negative on retesting without any treatment, 5 gave a stronger Kahn and 5 a minor reaction. Of the 36 +++ Kahn,

districts. Altogether 1,520 tests were done, including a few teachers. The findings are given in table XII.

Of the total number of positives, namely 64, 28 were over 15 years of age, above puberty, 19 males and 9 females: 2 of the males were teachers, and another, a man, admitted infection, in one case a married student and his wife were

TABLE XII

Routine Kahn tests on school children and young students

Total number ..	1,520
Kahn negative ..	1,226
± ..	161
+ ..	69
++ ..	33
+++ ..	16
++++ ..	15
	4.2%

both positive. Therefore, it is probable that hereditary syphilis, assuming the Kahn test to denote syphilitic infection, is considerably less than 4.2 per cent indicated. The number of positives varied considerably in the different schools, in some being nil, and in one as high as 14.3 per cent of 63 boys—only 2 of these positives were 15 years of age, the rest younger.

Discussion

Having now completed the general analysis of the figures, the question arises as to the interpretation of the Kahn test in relation to syphilitic infection.

One of the most recent surveys in the evaluation of serological tests for syphilis is that of the Committee of Evaluation of Serodiagnostic Tests for Syphilis following the Washington Serology Conference in 1941 under the auspices of the United States Public Health Service (Gradwohl, 1944). Two diseases only are singled out as liable to give a positive Kahn test apart from syphilis, namely leprosy and malaria. In our series only 1 patient was noted as suffering from leprosy and he had a negative Kahn and 13 patients were diagnosed as having malaria only and one only had a ± Kahn. The Committee regarded the Kahn test as 100 per cent specific in all other diseases tested including a series of tuberculous patients of all stages of the disease. Evidence has however been published elsewhere from time to time of a transitory positive Kahn in certain types of bronchitis and pneumonia although these are not numerous. In our series we had a number of patients with non-tuberculous chest diseases and in some of these we did get a higher percentage of positives, namely, in tropical eosinophilia 15.6 per cent. The finding of a higher percentage of Kahn tests in cases of tropical eosinophilia than in a general series was pointed out by Fridmott-Moller and Barton (1940) in a series, part of which is included in our present series of routine tests. Menon (1945) recorded that a positive Wassermann with a doubtful or negative Kahn was a common finding in tropical eosinophilia, and D'Abrera and Stork (1946) agreed with him. Our series was not controlled by the Wassermann but we did get a much higher percentage of positives in the tropical eosinophilia, 15.6 per cent as compared with the general

average of 6.6 per cent. Also in a small series of non-tuberculous pneumonia and pleurisy, we found 14.3 per cent positive Kahn. It is possible that the positive reaction in some of these was not due to syphilis: One case diagnosed as yaws gave a positive reaction.

On the other hand, a negative Kahn test is not proof of the absence of syphilitic infection. The Committee's report referred to give it as 62.2 per cent specific in patients with various degrees of syphilis treated and untreated—in this it is about the same as most of the other tests reviewed including Wassermann.

Previous reports in India of routine investigations into the question of latent syphilis have mostly been carried out with the Wassermann test and not with the Kahn test. Greval, Sen Gupta and Das (1938) reviewed earlier work in which Iyengar (1919) found 22 per cent of a series of 400 Indian males positive, and Lloyd, Napier and Mitra (1930) found about 20.0 per cent positive. Their own conclusion was that the corrected positive Wassermann rate should be under 10.25 per cent, that is after omitting certain non-syphilitic cases which gave a positive reaction; for Europeans, they estimated it should be under 8 per cent. Subsequently, Greval and Sen (1942) modified this figure and came to the conclusion that the crude rate was under 8.7 per cent and the corrected rate under 5.3 per cent.

In our series of cases we did not get the type of case which Greval and his co-workers found to produce a non-syphilitic positive Wassermann, except the tropical eosinophilia and non-tuberculous pneumonia series, a small group compared with our large series of figures for the tuberculous patients.

Our series has a possible disadvantage in that all positives were not controlled by a second test, but when retesting was done, no +++ or ++++ Kahn was found to become negative or doubtful without treatment. A small number of the ++ reactors became negative or doubtful without treatment, but these are balanced by some negative and doubtful Kahn which later proved to be positive. Therefore the omission of retesting for all our sera giving a Kahn reaction doubtful or positive probably does not affect our general conclusions.

Our figure of 6.6 per cent positive Kahns, taking this as indicating latent syphilis, is not very much higher than the 5.33 per cent of Greval and Sen for their Wassermann series.

It might be discussed as to how far our series is a fair sample of the population. Although no patients came because they thought they were suffering from venereal disease, yet there has been a certain unavoidable amount of selection in the cases which would make the series not fully representative of the whole population. The percentage of educated and more well-off patients is higher than would be found in the general population and specially is this true of the patients from the further parts of India. But nevertheless the series of patients does cover

a wide range of all classes of patients and different social status, occupations and religions, and national communities.

The evidence of inherited infection is that it is very low, both judged from the series of patients (table III) and the school children (table XII).

From what is known of the figures for latent syphilis from other workers, there seems to be ample evidence in our series to support the view that tuberculosis does not influence the Kahn reaction.

Summary

1. As a contribution to our knowledge of the prevalence of venereal disease in India, a study has been made of routine Kahn tests and of the medical histories of patients admitted to the sanatorium at Madanapalle since 1930.
2. Of 6,324 patients in whom the Kahn test was done the percentage of positives was 6.6.
3. The results have been analysed according to sex, age, marital status, community, province and occupation.
4. A history of venereal disease was given by 4.4 per cent of the patients.
5. The results of a separate series of routine Kahn tests on 1,520 school children and young students show 4.2 per cent positive, but some of the positives were above puberty.
6. The figures are discussed and compared with other work reported in India and found to be a little higher than the figures of Greval and Sen for the percentage of latent syphilitic infection.
7. Tuberculosis does not seem to influence the Kahn reaction.

Acknowledgments

We thank Dr. Margaret Rottschaefer of Wandiwash, North Arcot District, for permission to use the results of the series of Kahn tests done for her on school children and young students. We also wish to acknowledge the help of a few members of our staff with the Cope Chat cards, particularly Mr. C. P. Verghese.

THE WASSERMANN POSITIVE RATE OF CASES FROM HOSPITALS AND VENEREAL CLINICS OF CALCUTTA IN 1939, 1943, 1944, 1945 AND 1947

By S. D. S. GREVAL

LIEUTENANT-COLONEL, late I.M.S.

A. B. ROY CHOWDHURY, M.B.

and

B. C. DAS, M.Sc.

(From the Department of Imperial Serologist, School of Tropical Medicine, Calcutta)

IN two previous papers in this journal (Greval and Roy Chowdhury, 1944; Greval, Roy Chowdhury and Das, 1945) the writers gave comparative figures for (i) a normal pre-war period in 1939, (ii) a period during the war before the commencement of the anti-venereal drive in Calcutta in 1943, (iii) a period after the commencement of the anti-venereal drive in 1944, and (iv) a period when the drive had passed its peak in 1945. To these they now add figures for 1947, from hospital cases only.

Previously the writers, basing the presumption of a recent infection of syphilis on a +++ reaction, concluded that there was no increase in the incidence of syphilis in Calcutta. The number of positive cases had increased because the population had increased. The increase was proportionate. It is more than probable that a relative decrease might have been recorded but for the publicity of the anti-venereal drive. They also concluded that as the incidence rate was constant the source of infection must have remained constant. The number of the infected women was probably the same only their clientele had increased. The view fitted into their housing and rationing difficulties during the period under consideration. They, further, observed that there was a definite decrease in the intensity of the +++ reaction. This in all probability was due to the free treatment.

Observation on the figures and associated considerations

The +++ reaction.—This is the reaction given by the syphilitic sera with uncholesterinized Wassermann reaction antigen. Typically, it is the reaction of recent untreated cases of secondary syphilis.

Cases selected for Wassermann reaction.—With the exception of a small hospital all the hospitals in Calcutta and even the V.D. Clinics select cases for the Wassermann reaction. The positive rate, therefore, is of a suspected population, not of a random sample. It is not the rate for Calcutta as a whole.

From table I it will be seen that on the whole the positive rates have remained of the same order from 1939 to 1945. The strongly positive rate for the hospitals (as opposed to the V.D. Clinics) this year is the lowest on record in Calcutta since

1939. This may be due to the free treatment of syphilis before hospitalization or to the general trend towards decrease of the incidence of the disease in Calcutta due to increase in the hardships of life. The senior writer believes that syphilis in Calcutta is declining and was never really a menace as it has been made out to be.

The introduction in Calcutta of new strains of the spirochæte from the other hemisphere, during the war, was likely. They have not increased the total incidence of syphilis. Whether, as another result, neurosyphilis will appear (or increase if the present negligible figure is taken account) in due course, remains to be seen. The

TABLE I

Showing the Wassermann positive rate of cases from hospitals and venereal clinics of Calcutta in 1939, 1943, 1944, 1945 and 1947

Periods	Number of cases tested	POSITIVE REACTIONS, ALL GRADES (+, ++ AND +++)		STRONGLY POSITIVE REACTIONS (+++ ONLY)	
		Actuals	Percentage of the total	Actuals	Percentage of the total
<i>In 1939 :</i>					
I. 11-4-39 to 8-5-39, 15 working days	1,000	146	14.6	55	37.7
II. 9-5-39 to 3-6-39, 16 " "	1,000	204	20.4	57	27.9
<i>In 1943, before the anti-venereal drive :</i>					
III. 2-1-43 to 23-2-43, 34 working days	1,000	235	23.5	91	38.7
IV. 23-7-43 to 29-8-43, 25 " "	1,000	275	27.5	51	18.5
<i>In 1944, after the anti-venereal drive :</i>					
V. 22-2-44 to 13-3-44, 13 working days	1,000	337	33.7	121	35.9
VI. 14-3-44 to 30-3-44, 10 " "	1,000	351	35.1	104	29.6
<i>In 1945, after the anti-venereal drive had passed its peak :</i>					
VII. 6-3-45 to 16-3-45, 8 working days	1,000	229	22.9	47	20.5
VIII. 19-3-45 to 29-3-45, 8 " "	1,000	221	22.1	46	20.8
IX. 25-6-45 to 10-7-45, 7½ " "	1,000	242	24.2	87	35.9
X. 12-7-45 to 20-7-45, 7 " "	1,000	255	25.5	87	34.1
XI. 1-8-45 to 10-8-45, 9 " "	1,000	253	25.3	85	33.5
<i>In 1947, from hospitals, as opposed to anti-venereal clinics, comparable to figures in 1939 and 1943 :</i>					
XII. 24-4-47 to 23-6-47, 23 working days	1,000	250	25.0	35	14.0

TABLE II

Showing the ratio of new and old cases at different periods

Hospitals	Period	TOTAL NUMBER OF CASES		Ratio of new to old cases
		New	Old	
Medical College V.D. Clinic ..	V and VI	1,566	5,143	1 : 3.28
	VII and VIII	940	9,668	1 : 12.85
	IX	338	2,038	1 : 6.02
Campbell V.D. Clinic ..	V and VI	1 : 3.0
	VII and VIII	1 : 6.0
	IX	1 : 5.0
Lady Dufferin V.D. Clinic ..	V and VI	218	606	1 : 2.77
	VII and VIII	119	1,510	1 : 12.68
	IX	112	999	1 : 8.91

Two conclusions emerge : (1) the apparent vagaries of periods marked VII and VIII are due to more treated cases being tested in these periods than in others,

(2) the new cases have decreased markedly and steadily.

This fact is not in favour of the increased incidence of syphilis in Calcutta during the period.

presumption is that it will not appear. The static population of the town was hardly in touch with the mobile population, in spite of the total nature of the war. Besides, the identity of a neurotropic strain has not really been established.

The figures have been collected serially from the register in batches of 1,000, with a view to bringing out the usually occurring differences between batches of this magnitude.

The apparent vagaries of periods marked VII and VIII were enquired into with respect to the ratio between the new and old cases. The results are given in table II.

SEROLOGICAL TECHNIQUE (contd.)

By S. D. S. GREVAL

LIEUTENANT-COLONEL, late I.M.S.

(From the Laboratory of the Imperial Serologist and Chemical Examiner to the Government of India, School of Tropical Medicine, Calcutta)

False LCF (WR) Reactions

False positive reactions.—The following conditions have been held responsible for a false positive reaction: (1) Other diseases—leprosy, yaws, malaria, dengue, trypanosomiasis, pinta, bejel and atypical pneumonia frequently; septicaemia, endocarditis, pneumonia, tuberculosis, relapsing fever, spotted fever, typhus fever, scarlet fever, infectious mononucleosis, pernicious anaemia, leukaemia, xanthomatosis, severe jaundice and lymphogranuloma inguinale less frequently; other morbid states very infrequently. (2) Bacterial growth in serum. (3) Excess of fat and digestive products in serum. (4) Passive transfer from the mother. (5) High barometric pressure. (6) Improperly prepared, titrated and mixed reagents. (7) Probably some 'cured' cases of syphilis. Item 6 may be eliminated. It has no place in a standardized and controlled technique.

Attention has been drawn by the author to three other conditions: (1) Kala-azar. Some cases give an undoubted positive reaction which disappears when the disease is cured. (2) Leucithinophile eosinophilia. Many cases of asthma and other allergic conditions showing a marked eosinophilia also give a positive reaction which increases and decreases with the symptoms. (3) Leucithinophile hepato-gastro-intestinal syndrome. It is a state of ill health (i) characterized by chronic indigestion, distension after food, looseness of bowels or constipation, enlargement of liver with or without jaundice, discomfort or diffuse pain in the epigastrium or right hypochondrium, low fever, loss of weight, anaemia and a positive or doubtful

LCF and (ii) not covered either by a definite diagnosis of a known disease of the digestive system or by a diagnosis of syphilis. All the signs and symptoms may not and usually do not occur together. A strong enough combination in the absence of the usual manifestations of syphilis, however, establishes the presumption that one is not dealing with intentionally concealed, naturally latent or congenital syphilis but with a chronic and hitherto undescribed disease or disorder of the digestive system. The presumption is converted into proof when the positive or doubtful reaction weakens and disappears with the improvement and re-appears with the relapse. The condition is not syphilitic. The positive or doubtful LCF is false.

Latterly a post-vaccination period of 4 months has also been held responsible for simulating reactions of syphilis. These false reactions appear to be obtained mostly with flocculation tests. Immunization with tetanus toxoid also interferes.

False negative reactions.—Weak or even negative reactions of the blood in early and late syphilis are well known. What is not so well known is that for no apparent cause the bloods of thirty per cent of the patients slowly revert to negative, even though they may show definite signs of syphilis during this period: hence the specially sensitive antigens used for clinically known cases. An error on the right side resulting in such cases being reported 'doubtful' or even 'weakly positive' will suggest to the clinician the need for a thorough examination of the nervous and the cardiovascular system.

The New Name for the Wassermann Reaction, Lecithin Complement Fixation (LCF)

The original technique of the reaction was materially different from the present techniques. It depended upon the use of a restricted quantity of the haemolyticamboceptor and an excess of the complement: it was a qualitative test. The present-day techniques of most workers in England and America depend upon the use of an excess of theamboceptor and a restricted quantity of the complement: they provide a quantitative test. In America the reaction has been re-named after the serologists who have introduced the modification. The author suggested several years ago that it should be re-named Lecithin Complement Fixation (LCF). The name which has been adopted in the Carmichael Hospital for Tropical Diseases, Calcutta, is particularly useful in the tropics (and elsewhere too in cases with tropical histories) in allaying the alarm caused by doubtful, '50 to 90 per cent positive' and even positive Wassermann reactions. Diseases other than syphilis can undoubtedly be responsible for the reaction in the tropics.

The active substance in the antigen is presumed to be chiefly lecithin. It may be another allied lipid, or it may consist of several

lipoids. The letter L will represent one or more lipoids.

Repetition of LCF Reaction

1. Repetition necessary for diagnosis

When a suspicious primary lesion exists, and the first report is negative or doubtful.—If the treponema cannot be found, the reaction must be repeated fortnightly or weekly for 3 months from the date of the exposure. Diagnosis and treatment must be postponed. Otherwise the patient may have to submit to a lengthy treatment and life-long anxiety on suspicion alone.

If the risk has been taken with a partner who has later shown definite signs of primary or secondary syphilis, repeated clinical examinations and blood tests must be again continued for 3 months from the date of the exposure. Early primary lesions may be difficult to exclude in the female.

When a case of gonorrhoea has been treated with penicillin.—Observations, clinical and serological, may be necessary for 6 months.

When a case with equivocal signs of late syphilis has given a negative or doubtful reaction.—Further observations are obviously necessary, including blood tests. The fact that many syphilitics begin to give a negative reaction after a mere passage of time has been mentioned.

When syphilis of the nervous system is suspected.—The CSF is also to be tested with or after the blood.

When other conditions (febrile diseases in general, and certain tropical diseases in particular) known to give rise to a false positive LCF reaction are present.—These conditions have been mentioned. The reaction is repeated after they have abated.

When a treated woman has become pregnant.—The slightest departure from the negative reaction is important in the interest of the offspring, for those who do not treat every pregnant woman with a mere history of syphilis.

Women tolerate the disease much better than men, probably because of the chemical changes associated with the menstrual cycle and especially the changes associated with pregnancy. It has been noted that repeated pregnancies tend to cure the disease in women and to prevent serious nervous complications, especially if pregnancy occurs in the first few months of infection.

When a positive or doubtful LCF reaction has been found accidentally in an otherwise healthy subject, such as a donor of blood.—Latent syphilis must be excluded by further tests of blood and CSF.

The author's figures for latent syphilis in Indians, very much lower than those of other earlier workers, are :—

Crude rate (found initially)	8.7 per cent
Corrected rate (persisting finally, without anti-syphilitic treatment under	5.3 per cent

These figures were obtained from the Indian population of Calcutta not yet affected by the Second World War. In the country the rate must be much lower.

When a positive LCF reaction is not compatible with one's judgment of the patient's character or heredity.

2. Repetition necessary for treatment

When the blood is tested as a measure of the treatment.—A fall in the degree of fixation of the complement will indicate (i) whether the drug selected is making an impression on the system of the patient at all, and (ii) whether enough treatment has been given. Both indications are important: one may be dealing with conditions in which reaction and poisoning are feared and therefore the mildest remedies are used, as in cardiovascular disease, hepatic disease, advanced age and pregnancy: or one may be dealing with resistant cases and tough constitutions, and heroic measures may be needed.

Negative LCF at the end of a 'course' but after an 'interval' is the aim of treatment. Several courses may be necessary to attain this aim. Some extra treatment is then given.

Cases are known in which all treatment fails to influence the LCF. When after a long treatment, suitably given, the LCF reaction is still positive, suspension of further energetic treatment is justified if (i) the CSF is negative and normal and (ii) the cardiovascular system is sound or if (iii) the patient is elderly.

3. Repetition necessary for test of cure

When a cured case is being tested periodically.—The length of the intervals varies with the physician's confidence in his treatment and with the patient's financial status, from 3 to 6 months. The total duration of the periodical tests also varies with the purpose: 2 years after suspension of treatment, as a rule; 5 years after infection, for marriage (in the male, can be shortened by treatment to 4, *vide infra*); and whole life for general observations. The whole life repetitions may be annual.

As to the minimum period of subsequent observation, an analysis of the result of treatment of early cases at the St. Thomas' Hospital V.D. Centre, London, showed that by far the majority of relapses occurred within 6 months following suspension of treatment and that relapses were very uncommon in the second year and very rare after the end of 2 years. The minimum for early cases should, therefore, be 2 years.

The above remarks apply to blood only. The CSF also should be tested during the fourth and tenth year. The first is the end of the period when the changes found in the early syphilis have disappeared in a proportion of cases. The second examination is best calculated to catch those cases where the fluid, having been rendered normal, has relapsed.

The seasonal variations in the LCF reaction and in the quality of the complement of the guinea-pig serum on which so largely depends the degree of fixation are vital considerations. If possible, the repetitions should be made in the same season (or seasons).

The foregoing account was based on the result of the usual treatment with arsenic and bismuth. Opinion based on the results of treatment with penicillin cannot yet be given. After a 'course' of penicillin treatment the positive WR is not reversed as rapidly as after a course of the other treatment. The 'course' itself is as yet undefined. (The rapid method of treatment with arsenic and bismuth cannot be recommended.)

Certain Preparatory Measures

Food before giving blood.—The ideal time for giving blood for the test is early in the morning before taking any food. After that, any time before the heavy meal of the day (morning meal and lunch) will do. If this precaution has been ignored for the first test, it should be taken for the second and recorded.

Cloudy chylous sera are on the whole unstable, and more likely, therefore, to give a false positive (or doubtful) reaction.

Withholding a protein diet for 3 days.—A recent advance in the serology of syphilis advocates withholding all animal protein for 3 days before retesting the blood. The subject under test is put on a milk-free, meat-free diet, with fresh vegetables and fruit juices *ad lib.* and six to eight glasses of water daily for 3 days.

The author has tested this plan in a short series of cases, and in some Indian patients (strict vegetarians) withheld wheat and pulses also. He has obtained definite quantitative reduction and at times a qualitative change in the doubtful reactions of some cases. The plan may differentiate between specific and non-specific cases when clinical examination and history fail. It is worthy of trial.

Provocative injection.—The author is against the use of this measure. It is as likely to provoke a non-specific reaction as a specific reaction, and in India the causes of non-specific reactions are many. The provocative injection in the military hospitals has been given up in the diagnosis of early syphilis.

The Blood Test Obsession

Cases presenting themselves again and again for blood tests and also going for treatment from physician to physician are frequently encountered. Their attention should be drawn to the following facts and conclusions:—

1. *False positive LCF reactions are quite common in India.*—All conditions known to be responsible for them should be excluded before a lapse in the more or less remote past is accepted as the starting point of syphilis.

2. *Syphilis does not play the same havoc with the human body in India as in Europe.*—Late

and intractable effects of the disease are borne by very few victims indeed. GPI is a rarity against '500 to 700 cases treated yearly since 1927' in England. Tabes is almost as rare, at least the typical case. Cardiovascular diseases do exist but, excepting the aortic disease, their victims are found living useful lives, almost approaching the normal, with ease.

If syphilis in India were not so tame, the country, consisting as it does of masses whose buying power (including procuring of appropriate treatment) is so low, would not have shown such an increase in population at each census, even though the social conditions minimized the incidence of the disease.

3. *The possibility of the involvement of the nervous system and the cardiovascular system can be excluded by the detailed examination of the CSF and the heart.*

4. *A syphilitic male is not likely to infect his wife or offspring, 5 years after the infection, regardless of the treatment or cure, even in Europe.*—In India probably the same happy immunity is available earlier.

5. *A woman stands syphilis much better than a man, even in Europe.*—In India her chances of curing herself by her own biochemistry must be better.

6. *An infected expectant mother treated in the first half of the pregnancy can have a healthy offspring.*—Again, chances in India must be better.

DETAILS OF COMPLEMENT FIXATION IN GONORRHOEA

The Technique

The hæmolytic system.—This is taken from the LCF reaction, observing the same rule of preference for the complement.

The antigen.—A gonococcus vaccine containing 500 million organisms per c.c. and obtained from a manufacturing institute suffices. The author obtains his supplies, in 1 c.c. ampoules, from the Central Research Institute, Kasauli, and finds them satisfactory. The polyvalent character of the vaccines and the time taken in ampouling it have been described thus:—

'The seed of our gonococcus vaccine is selected to include six strains, if these are available at the time of preparation, but at least two strains are used for each brew.

The interval between washing and ampouling may vary, depending on supply and demand, from about one month to six months'.

The need for polyvalency in gonococcus suspensions for the purpose of this reaction has been overstressed. Even if evidence of several strains be admitted there remains *one very large main group* which is representative of the species. The strains are not comparable to the *type* of the meningococcus.

A 1 in 5 dilution of the contents of one ampoule from each batch of the vaccine is tested for anticomplementary and hæmolytic

activity. One volume of it should not interfere with 1 MHD of complement and 3 volumes should not hæmolyse 1 volume of the sensitized rbc suspension (details under LCF antigen).

The serum. 1. *Under test.*—It is inactivated immediately before use and diluted 1 in 5, 1 in 10, and 1 in 20. *If possible it should be taken in the laboratory from the patient:* otherwise it should be taken and preserved with special care and *not allowed to become anticomplementary.* The ideal time for taking blood is early morning before any food. After that any time before the heavy meal of the day will do.

2. *Known positive.*—A positive serum of known titre is diluted 1 in 5 with saline containing 0.25 per cent trikresol and kept in the refrigerator.

3. *Known negative.*—When a positive serum is available only 1 negative serum is enough as a control. Otherwise at least 6 controls, 3 from positive cases of syphilis and 3 found negative by LCF, are required. Serum from a subject with a bad throat (likely to harbour gram-negative cocci of the genus *Neisseria*) may also be included.

Charging of the tubes.—For each serum 4 tubes are used in a column and charged as follows:—

A Column

2nd, 3rd and 4th row tubes contain antigen 1 volume and complement $1\frac{1}{2}$ MHD contained in 1 volume.

4th row tube Serum dilution, 1 in 20, 1 volume.

3rd row tube Serum dilution, 1 in 10, 1 volume.

2nd row tube Serum dilution, 1 in 5, 1 volume.

1st row tube Serum dilution, 1 in 5, 1 volume, saline, 1 volume (no antigen).

(Antigen and complement are mixed and delivered as a double volume *after* the serum has been delivered)

Left (i) at room temperature $\frac{1}{2}$ hour, (ii) in incubator $\frac{1}{2}$ hour, (iii) at room temperature 5 to 10 minutes, until the tubes do not feel warm, (iv) in ice box for $\frac{1}{2}$ hour, (v) at room temperature for 5 to 10 minutes, until moisture does not condense on the tubes.

The order is important. If the tubes are left in the ice box first, anticomplementary action of some old sera becomes more marked.

Sensitized rbc 1 volume added to all tubes.

Incubation $\frac{1}{2}$ hour.

An antigen control is included for the day's work. It consists of (i) antigen 1 volume +, (ii) complement 1 MHD in 1 volume +, (iii) saline 1 volume. It is left at various temperatures in the same rack as the other tubes and tested for loss of complement by adding rbc suspension 1 volume. The rbc should be almost completely hæmolyzed.

Reading of results.—The results are read (i) immediately for \pm and —, and (ii) next day for + and T, after the tubes have stood in the ice box overnight. A ? is ignored and classed with — (details under LCF).

The positive and negative controls (at least the majority of negative controls) should give the expected reactions.

Record and report. 1. *When the serum control is fully hæmolyzed.*—A + recorded under its appropriate tube is reported as 'Positive in 1 in 20', 'Positive in 1 in 10' or 'Positive in 1 in 5'. A T or \pm in one or more tubes is recorded under each tube and reported 'Doubtful'. A sustained partial but well-marked inhibition of hæmolysis in all tubes is more important than a \pm in one tube (the 2nd tube with serum 1 in 5) only. History will decide the significance in all \pm cases.

2. *When the serum control is partially hæmolyzed (\pm).*—A + in the 3rd or 4th tube is reported as 'Positive in 1 in 10' or 'Positive in 1 in 20'. For a + in the 2nd tube only the serum must be diluted and tested until the 1st tube is fully hæmolyzed.

3. *When the serum control is not hæmolyzed at all or shows only a trace of hæmolysis (+ or T).*—Record + or T. No report is possible. Dilute the serum for further tests.

Observations on the Technique

The quality of complement fixation.—The reaction though specific is weak. Because of this weakness some workers do not employ a fixed period of incubation after adding the rbc suspension. The incubation is continued, while the tubes are being examined again and again, until the expected reaction is obtained. The inhibition of hæmolysis under such condition is not perfect and the reaction is hardly repeatable.

It may be added that the positive rate increases with the duration of the infection, specially with complications of the subacute and chronic stages. The reaction, therefore, is likely to give aid when such an aid is most needed. Unlike the LCF, however, it is not positive in all cases of gonorrhœa even in chronic stages.

For acute and sub-acute cases there is hardly a need for the reactions.

Special features of the technique.—There are 6 such features: (1) the antigen is easily available, (2) the dose of the antigen is linked to the MHD of the complement, (3) the dose of the complement is restricted as much as possible, (4) complement of a poor quality is not used, (5) cold fixation is also employed, and (6) a perfect inhibition of hæmolysis is insisted upon for a + although T and \pm are considered significant.

Repetition of the Reaction.

For technical reasons.—From what has been said concerning the preference for the qualities of the complement, it follows that a doubtful

Discussion

Rein and Elsberg found post-vaccinial serologic reactions for syphilis in 44.9 per cent of their series. They examined seropositive cases every week till they were negative. Tetanus toxoid and T.A.B. inoculations were also given to those cases on the same day in addition to smallpox vaccination. They state in a review of the literature on the subject that Arthur and Hale found positive serologic reactions in 14.8 per cent of 95 soldiers who had received routine army immunization against smallpox, tetanus and yellow fever and Lynch and Favourite found 16 and 11.8 per cent respectively of seropositive cases after smallpox vaccination. Doubtful or positive W.R. and/or Kahn tests were observed in 14.3 per cent of the 42 cases of the writer's series. These cases were examined on the 6th and 17th days only. Rein and Elsberg attributed the low incidence rate of false positive reactions observed by other workers to their testing blood only once and collecting blood too soon after vaccinations. They recorded maximum number of seropositive cases in the 3rd week. 7.1 per cent of the writer's series showed serologic reactions on the 6th day

and 17.4 per cent who were seronegative on the 6th day became seropositive on the 17th day. The percentage of cases with positive serologic reactions in the present series would have been obviously more than 14.3 if they could be tested more frequently. Rein and Elsberg observed that 4 units took 2 or 3 months or longer for seroreversal. In the present series, cases 1 and 4 who showed 4 Kahn units on the 6th day were seronegative on the 17th day, and cases 7 and 8 who had 4 and 2 Kahn units respectively on the 17th day were seronegative on the 33rd day. Case 3 was the only one amongst 8 cases with post-vaccinial serologic reactions who was seropositive on the 33rd day.

Rein and Elsberg did not investigate the serologic reactions in the cases who showed immune reaction after vaccinations. They however mentioned in the review of the literature the work of Favourite and Lubitz who reported absence of serologic reactions in cases that developed immune reaction after vaccination.

No accurate record is available with the writer about the types of reactions after vaccinations in the present series except that 3 out of 42 cases developed vaccinia type of reaction. Only one out of these 3 became seropositive.

Summary and conclusion

Forty-two cases who had W.R. and Kahn tests negative before vaccinations were investigated for false positive post-vaccinial serologic reactions. 14.3 per cent of these cases showed positive or doubtful W.R. and/or Kahn tests. The incidence of post-vaccinial seropositive cases would have been higher than this if they had been tested more frequently.

I take this opportunity to thank the officer commanding the camp and British and Ceylonese non-commissioned officers for their help and co-operation and Brigadier C. A. Slaughter, R.A.M.C., D.D.M.S., Ceylon Army Command.

A Mirror of Hospital Practice

A CASE OF SYPHILIS OF THE LUNGS

By BENOY SINHA, M.B.

Surgeon, Venereal Department, Campbell Medical School and Hospital, Calcutta

SYPHILITIC infection of the lungs is rare.

The present case was referred to me by a colleague. One skiagram he brought with him and two more were taken by me.

The patient, N. M. K., was an Afghan by birth and money-lender by profession, aged 40; weight 14½ stones; height 6 ft.; health apparently good.

Complaints :—

1. Persistent cough—whole day and night.
2. Sticky phlegm.
3. Sudden hæmoptysis lasting a few days; recurrence thrice.
4. Loss of appetite—feeling run down with weakness of his both lower limbs.

Past history :—

About 12 years back he had an attack of hæmoptysis.

Fig. 1.—Case of secondary syphilis looks like sycosis barbae.

Fig. 2.—Hyperkeratotic type of rash in secondary stage of syphilis giving a leonine face.

Fig. 3.—Case of destruction of nose and lips with closure of mouth and nasal orifices as a result of late syphilis.

Fig. 4.—Destruction of bridge of nose with the overlying skin in a late syphilis.

(Negative damaged during storage)

He admits illicit connections and an ulcer on his genital organ when he was 20 years old—he had no secondary rash.

The patient had no complaints of slow fever, wasting or night sweats; he had no pain in the chest either.

Blood for W.R.—positive.

Sputum after repeated examination—Acid fast bacilli, none found.

Blood counts :—

Hæmoglobin—85 per cent.

Erythrocytes—4,700,000 per c.mm.

Leucocytes—9,600 per c.mm.

Polymorphs—72 per cent.

Lymphocytes—23 per cent.

Monocytes—0 per cent.

Eosinophiles—5 per cent.

Parasites—none found.

Physical signs :—

Râles and rhonchi were present.

X-ray findings.

Part examined—postero-anterior at two metres.

Fluoroscopy—

Apices clear. Illumination normal.

Diaphragm movements poor, the angles are clear.

Skiagram—

Evidence of old infiltration, more or less throughout right lung field, but most marked in the middle and lower zones; on the left side there is radiative fibrosis spreading out from the hilum.

Differential diagnosis :—

1. Tuberculosis of the lungs.

No pain in the chest, no wasting, no fever nor night sweats; sputum was found negative. Apex of the lungs not involved.

2. Cancer of the lungs.

No signs of rapid new growth; no pain nor fever; no deterioration of health.

Provisional diagnosis :—

Interstitial type of syphilitic lungs.

Fibrosis at the root of the lungs; history of sore on the penis due to illicit connection; W.R. positive.

The patient started improving with anti-syphilitic treatment.

He suddenly left India after receiving ten arsenic and eight bismuth injections. No further skiagram was taken.

[This was the position before the false W.R. of the atypical pneumonia was made known. Now to exclude the latter disease a concurrent estimation of the cold agglutinins will be necessary.—Editor, I.M.G.]

Occasional Notes

CAPILLARITY PHENOMENA IN GONOCOCCAL INFECTION IN THE MALE URETHRA

By BENOY SINHA, M.B.

Surgeon, Venereal Department, Campbell Medical School and Hospital, Calcutta

Just as a matter of curiosity, without attaching any importance to the diagnostic or curative value, I was interested in knowing how the entrance of the gonococci is effected from the female genital organ into the male genital organ during sexual intercourse which is indeed the most common source of infections.

Anatomically the male urethra is a potential cavity, the walls of which are normally kept in apposition except during micturition or emission of semen. During coitus, the penis, under the influence of erotic impulses, gets erected, swollen and hard which state makes the lumen of the urethra more firmly constricted—the walls of the urinary passage become temporarily more apposed. During this physiological condition of the penis, the actual process of transference of gonococci into the male urethra, and the distance covered by them at one stretch of ascendance, before they lodge themselves in some protected area just to spend their hours of incubation period, as a prelude to further upward invasion have, no doubt, much significance with reference to abortive or curative line of treatment. If the process of infection by the gonococcus, its first range of attack and the time taken for it, are ascertained, the modern conception of anterior urethral wash by antiseptics will be completely overhauled.

The mucous membrane of the anterior urethra consists of columnar epithelium except in the fossa navicularis which consists of squamous and stratified varieties. This again rests on the submucous vascular layer.

It is almost an accepted fact that the cylindrical epithelium has got greater affinity for the gonococci than the squamous or stratified epithelium.

During their entrance into the urethra gonococci have evidently got to pass through fossa navicularis without affecting it till they reach the region covered with cylindrical epithelium where the gonococci find a favourable accommodation for their propagation.

During coitus, is there any action like suction which is responsible for the above access of the gonococci into the urethra? Let us compare urethra with a dropper. Pressure is applied on the top of a dropper, column of air is driven out to create a vacuum which, on release of pressure, draws fluid in.

Does gonococcus enter the male urethra after the manner of sap in plants, oil in wicks, water in sponge or ink into blotting paper also?

During erection the lumen of the urethra is obliterated owing to firm apposition of its walls which get equally swollen due to congestion. The greater the congestion of the vessels the stronger the erection of the male genital organ and the more firm is the apposition of the walls of the urethra. During coitus, when the curve of orgasm is on its ascending order, the passage of the male urethra being thus closed, entrance

of the diplococci into the urethra receives natural obstruction.

When orgasm has reached its highest peak, the semen is squeezed along the urethra by rhythmical contraction from behind forwards and is emitted with some force. With the ejection of semen, spasms of the penis gradually wane, and before there is complete relaxation of the penis the fine opening of the internal urethra becomes more or less akin to that of a narrow capillary tube. Into this capillary tube will rise infecting fluid from the vagina.

Therapeutic Notes

NOTES ON SOME REMEDIES

XIII.—DRUGS IN SYPHILIS

By R. N. CHAUDHURI, M.B. (Cal.), M.R.C.P. (Edin.),
T.D.D. (Wales), F.S.M.F. (Bengal)

*Professor of Tropical Medicine, School of Tropical
Medicine, Calcutta*

I. ARSENIC

THE arsenicals are classified into inorganic and organic compounds. The inorganic salts have long had a reputation in the treatment of malaria and syphilis, diseases caused by protozoa, and it was thought that they might be of use in sleeping sickness when it was found to be caused by trypanosomes, another protozoal parasite. The results, however, were disappointing because the arsenic could not be given in sufficient quantity without causing poisonous effect on the host. On the other hand, the organic compounds in which arsenic is combined with carbon appear to have the effect of reducing its toxicity, thus enabling more of the element to be given with correspondingly enhanced therapeutic activity. One of the first of these compounds that were tried was atoxyl, it proved useful in syphilis and trypanosomiasis, but while destroying the parasites it was not devoid of toxic effects. Ehrlich found that the pentavalent compounds like atoxyl are really inactive in themselves and only acquired activity when they are changed in the body to the trivalent arsenic and this led him to seek for organic compounds in which arsenic is trivalent. Of these salvarsan was introduced in 1910 and neosalvarsan a little later for the treatment of syphilis. Since then some powerful pentavalent compounds have also been prepared.

Drugs in common use

1. Trivalents

1. '606', salvarsan, arsphenamine. Owing to many disadvantages it is not used except in

the form stabilarsan which is a combination of arsphenamine and glucose and issued in ampoules in the form of a sterile solution. It should be diluted with 5 to 10 c.c. of sterile distilled water and injected intravenously.

2. '914', neosalvarsan, neoarsphenamine. It is manufactured under various names, e.g. novarsenobillon, neokharsivan. Although slightly less efficient than the original salvarsan, this is the drug most frequently used at the present time owing to reduced toxicity and ease of administration. The dose is 0.15 to 0.75 gm. per week. It is given intravenously dissolved in 10 c.c. of sterile distilled water, but as it is rapidly oxidized on exposure to the air, care must be taken to avoid undue aeration while preparing the solution.

3. Mapharside, mapharsen, neohalarsine. It was first synthesized by Ehrlich but was rejected by him owing to its supposed toxicity. Later experiments showed it much less toxic than neoarsphenamine, and owing to this reason it is now being used for intensive treatment of early syphilis, but it can also be employed in routine treatment. The dose is 0.02 to 0.06 gm. twice weekly. Its solution which is more stable is injected intravenously.

4. Sulpharsenamine, sulfarsenol, sulphostab. It is given intramuscularly or deep subcutaneously and is best reserved for cases in which intravenous injections are not possible. The dose is 0.12 to 0.6 gm. which is dissolved in 1 to 2 c.c. of water.

2. Pentavalents

1. The most important preparation is tryparsamide. It is of little value in acute syphilis and its chief rôle is played when the central nervous system is affected as in neurosyphilis and trypanosomiasis. Its molecular structure enables it to penetrate that system easily and act on the parasites. The dose is 1 to 3 gm. dissolved in 10 c.c. sterile water and the solution is injected once weekly intravenously.

Boiling of the solution should be avoided as it may produce toxic compounds. As the drug is liable to cause optic atrophy a careful watch must be kept on the eyes.

2. Acetarsol, stovarsol, or spirocide. It is given as tablets by the oral route but has a low therapeutic value in syphilis. The dose varies from 0.06 to 0.5 gm. daily and its chief sphere of usefulness is in congenital syphilis where for any reason more intensive treatment cannot be given.

3. Acetylarsan. It is a derivative of acetarsol and is given intramuscularly or deep subcutaneously. It is available in ampoules and the dose is 1 to 3 c.c. twice weekly. Its curative power is also low.

Mode of action

After intravenous injection, neoarsphenamine leaves the blood stream rapidly and is stored mainly in the liver; 60 per cent of the drug is excreted within seven days and most of the remainder in another week. More arsenic is excreted in the faeces than in the urine, the bile being the main channel of excretion. The pentavalent compounds are eliminated more rapidly than the trivalent. Arsenicals act in the body by breaking down to the arsenoxide form and liberating ionic arsenic. Interaction takes place between it and the tissues with the production of a substance which has the power of destroying the parasites. The curative action does not depend upon the amount of arsenic present in the compound but upon the amount which is therapeutically usable and this again is dependent on the molecular structure of the compound.

Toxic effects

The following are the more important, though uncommon, reactions after neoarsphenamine :

1. Nitritoid crisis. So called because it resembles the effect of taking nitrites. Following first or second injection a sudden vaso-motor reaction occurs, *viz* flushing of the face and neck, dyspnoea, dilatation of the pupils and tingling of hands and feet, sometimes with loss of consciousness. Later oedema of the face especially of the lips and eyelids may supervene. These appear during or immediately after the injection. The remedy is to stop the injection and give hypodermic injection of 0.5 to 1 c.c. of 1 : 1,000 solution of adrenaline. In subsequent injections adrenaline is similarly given half an hour before the arsenical is administered.

2. Herxheimer reaction ('Therapeutic shock'). This consists in lighting up of the syphilitic lesions from a few hours to a day after the first injection. The reaction disappears slowly and is of no importance in primary syphilis, but in late syphilis in which important viscera may be affected, grave symptoms may accompany such a reaction.

3. Jaundice. Usually it appears after 8 to 12 injections. It is now considered that jaundice occurring during the treatment of syphilis is frequently due to the contamination of syringe by the blood of a syphilitic who is carrying the virus of infective hepatitis and can be prevented by careful attention to injection technique and sterilization of syringes. When it occurs, the treatment with arsenic and bismuth must be discontinued for at least three months.

4. Dermatitis. Excepting transient cutaneous reactions in early stage acute exfoliative dermatitis is usually a late manifestation and may turn out to be a serious complication.

The new drug B.A.L. (British anti-lewisite), primarily developed during the war against the possible use of arsenical gas, has been found to be of value in this condition. It is injected intramuscularly in oily solution, the dose being 3 mg. per kilogram of body weight. It is given every four hours on the first two days, four times on the third day and twice a day for the next ten days. In mild cases smaller doses are sufficient. Side effects of the drug may occur, *e.g.* nausea, vomiting, burning of the lips and mouth, constriction of the throat and chest, for which barbiturates are used. After severe dermatitis patients should not be given arsenic again.

5. Encephalopathy. This is a very rare, but most serious complication. It supervenes within 24 to 36 hours of the injection and is more often seen in intensive arsenotherapy. The symptoms are severe headache, disorientation, mental confusion, convulsion and coma often ending in death. The treatment consists in (1) removal of spinal fluid if under pressure; (2) intravenous glucose and saline; (3) B.A.L. injections and (4) oxygen inhalation.

6. Purpura and aplastic anaemia—Rare.

Of the pentavalent compounds, acetarsol sometimes causes dermatitis. Tryparsamide is prone to exert toxic effects on the optic nerve, warning symptoms being dim and misty vision and contraction of the visual fields. Before each injection the physician should inquire as to the former and make a rough test of the visual field.

II. MERCURY

For centuries mercury was regarded as the only remedial agent for syphilis until superseded first by arsenic and then by bismuth. It has direct selective action on the spirochaetes though the action is slow. But its curative dose is so close to the poisonous that treatment was always a difficult matter and the results were sometimes so appalling that even the public got to know of them and dreaded the medicine than the disease itself. It is still occasionally used (1) in late syphilis, (2) in cardiac and neurosyphilis, (3) in congenital syphilis and (4) when the patient's occupation prevents from taking the regular treatment. By mouth the patient takes Liq.

hydrarg. perchlor., $\frac{1}{2}$ to 1 dr., or iodide of mercury, gr. 1/10, thrice daily for a period of 2 to 3 weeks in each month and this course may be repeated for several months. But the oral route though popular is inefficient and very prone to cause stomatitis and salivation. Inunction is better owing to more regular absorption and less disturbance of digestion but has the disadvantage of being inconvenient and uncleanly. A dram of mercurial ointment or the oleate is rubbed in daily (one day off in a week) for 30 minutes and continued for two to three weeks. Six such courses may be given in the first year and later at less frequent intervals. Mercury by injection is now little used.

Early signs of mercurial poisoning are salivation and gingivitis, followed by colic and diarrhoea. Later the patient becomes anæmic, emaciated and weak.

III. BISMUTH

In 1916 Saunton and Robert found that the sodium-potassium-bismuth tartarate was very effective in treating the spirochaetosis of fowls, and they suggested that the agent might have some value in syphilis. After various trials bismuth was recognized as a drug of considerable value and introduced in the treatment of syphilis in 1922 as an adjunct to arsenical therapy, in which capacity it has now almost replaced mercury, as being less toxic and more effective. As in the case of arsenicals, bismuth has no direct action, but exerts a lethal effect on the parasite only after coming in contact with the body tissues.

The drug is given intramuscularly in the buttock, care being taken not to inject into a blood vessel or pulmonary embolus may occur. Bismuth sub-salicylate in *oily suspension* is the preparation commonly used, the weekly dose being 0.2 gm. given in 1 or 2 c.c. of the suspension. The *oil-soluble* preparations of bismuth, e.g. bismuth ethyl camphorate, are useful when rapid action is desired; as these are absorbed and excreted more rapidly, injections must be given twice a week. Proprietary preparations of these salts are available in the market.

The toxic effects of bismuth are somewhat like those of mercury. In the early stage a blue line forms along the edge of the gums which become spongy and tender. In both mercury and bismuth treatment the mouth should receive thorough care.

Attempts have been made to produce a stable chemical union of arsenic and bismuth which would combine the anti-syphilitic properties of both. One such is bismarsen given twice weekly by intramuscular route in the dosage of 0.2 gm., dissolved in 1 c.c. of water. Four or five courses each of 8 injections are given at monthly intervals. Its use has not become very popular. The action is slow, but it appears to be well tolerated when it is not safe to give more active

preparations as in certain states of cardiovascular lesions.

IV. IODIDES

Iodides are used extensively in tertiary syphilis, their action is exerted not on the parasite but on the gummatous fibrous tissue which is the result of the infection. They help in the resolution of such tissue. Sodium and potassium iodides are most frequently prescribed in 30 to 60 gr. daily or even more according to tolerance, such large dosage being necessitated owing to their rapid elimination by the kidney. They are given for 3 or 4 weeks at a time followed by a rest of 2 or 3 weeks. Only after preliminary iodide therapy more potent drugs should be used in late syphilis.

V. PENICILLIN

One of the most surprising and least expected developments in penicillin therapy is the demonstration of its value in human syphilis. It is very active against the parasites in extremely high dilutions, but precisely what the minimum effective level is and how long it must be continued have not yet been satisfactorily determined. It is very suitable for early syphilis and for cases in which toxic effects prevent continuance of arsenic or bismuth. The immediate effects are very favourable—the surface organisms disappear in 12 to 24 hours, the lesions heal rapidly and the positive serological reactions become negative in 3 to 4 months. But as relapse occurs in a good proportion of cases the present tendency is to give, in addition, one course of arsenic and bismuth therapy.

Penicillin is probably the drug of choice for syphilis in pregnancy. In congenital syphilis the early results have been most encouraging. Late cutaneous and osseous symptoms respond promptly but no adequate reports are available on its action in latent syphilis. Recent reports on its use in neurosyphilis are more favourable than previous ones.

It is now recognized that there exists at least four main types of penicillin which, though affecting the same range of bacteria, differ quantitatively in their antibacterial power. For instance, penicillin II (or G in the U.S.A.) is much more efficacious than penicillin IV (K) in syphilis. Commercial penicillin is an unknown mixture of penicillins and in using it the physician has no assurance that the mixture will contain a preponderance of the type of penicillin which is most effective against the infection from which his patient is suffering. Until this and other matters such as their absorption and excretion are more clearly understood all treatment schedules must be regarded as in the experimental stage. In any case some years must elapse before its final value can be assessed.

Details of dosage will be given later.

150 years old...

1947 marks the 150th anniversary of Howards of Ilford, manufacturers of fine chemicals. Latterly, as most of our friends know, supplies have not been so freely available as they, or we would have wished, although conditions are improving. We would like to assure our friends, that we are doing our utmost to let our agents have everything we can spare, and that they, in turn, try to make the fairest possible distribution of what they get.

HOWARDS OF ILFORD

(Established 1797)

HOWARDS & SONS LTD., ILFORD, NEAR LONDON, ENGLAND

Agents in Asia for Howard's
Quinine and other fine
chemicals are:—

CHINA & HONGKONG

Messrs. A. R. Burkhill & Sons
Ltd., 1 The Bund, Shanghai.

INDIA

BOMBAY AREA: *The Anglo-Thai Corporation Ltd., Ewart House, Bruce Street, Bombay.*

KARACHI AREA: *The Anglo-Thai Corporation Ltd., Nadir House, McLeod Road, Karachi.*

CALCUTTA AREA: *Mr. Ralph Paxton, 10 Lall Bazar, Calcutta.*

CEYLON

Messrs. E. B. Creasy & Co. Ltd.,

The Anglo-Thai Corporation Ltd., Mercantile Bank Buildings, Singapore.

SIAM

The Anglo-Thai Corporation Ltd., P.O. Box 328, Bangkok.

VIROL

and the proper nutrition of children

For more than forty years doctors have been observing what happens to children when they are given Virol in addition to their ordinary meals. In Hospitals, Welfare Centres and in private practice they have seen over and over again how quickly the growing body responds to Virol and how lasting is the improvement in growth, health and energy.

Virol is a concentrated and very

palatable food prepared from Malt Extract, specially refined Animal Fats, Eggs, Sugars (including Glucose), and Orange Juice, with added Mineral Salts and Vitamins. Virol is designed to provide, in carefully balanced proportions, those essential food factors (not vitamins alone, but also many other just as important, including iron, calcium, phosphates, etc.) which are most likely to be deficient in the rest of the diet.

Agents for India:

Messrs. A. H. Wheeler & Co., Asian Building, Nicol Road, Ballard Estate, Bombay

Virol Ltd., London, England.

The Vitamin B group

**balanced for
effective
dosage**

Intensive dosage with a single member of the vitamin B group may precipitate a deficiency of some other member of the group. In the absence of specific indications, therefore, it is generally advisable to prescribe a preparation in which the members of the vitamin B group are all present in the proportions in which they are normally required.

Vitamin B Compound B.D.H. tablets provide an ideal means of administering this group of vitamins. They are indicated generally for the correction of states of lowered metabolism due to deficient diet or acute illness, and which are manifested as debility, lassitude, weakness, vague neuritic pains and undue susceptibility to exhaustion and infection.

Among the more specific indications is menorrhagia which has been shown, in some instances, to be due to vitamin B group deficiency with consequent impaired oestrogen inactivation by the liver. Vitamin B Compound B.D.H. is issued in bottles of 100 tablets.

VITAMIN B COMPOUND B.D.H.

THE BRITISH DRUG HOUSES LTD. Post Box 1341. BOMBAY No. 1
(Incorporated in England)

Vit B 1n/507

WATSON X-RAY EQUIPMENT

gives unfailing service because

- 1 it is designed by men of wide experience in every aspect of the electrical engineering involved, and possessing a practical knowledge of radiological requirements.
- 2 no design is based upon empiricism; the extensive research facilities of the G. E. C. Research Laboratories are employed to prove new theories—to investigate new methods and materials, and thus promote progress.
- 3 manufacture is conducted at Watson's Wembley factory by the aid of the most advanced precision machinery. Special jigs and tools ensure uniform accuracy and interchangeability.
- 4 tests at every stage of manufacture reduce the incidence of faults to the minimum. Nothing is allowed to leave the factory until it is as perfect as skill and knowledge can make it.
- 5 installation and servicing is carried out by fully-trained engineers most of whom have devoted the whole of their working lives to x-ray work.

OCTOBER

CONCERNING VENEREAL DISEASES

THE knowledge of venereal disease in India is mostly borrowed. While advances have been made in tropical medicine the original work on venereal diseases has been remarkably scanty, with the result that conceptions that are not quite up to date and, in addition, are not applicable to India are still entertained. Such are the supposed high incidence of syphilis in India and the usual dread of gonorrhœa. Then there are the ignorance of other venereal diseases and the inclusion of non-venereal conditions among the venereal diseases.

Syphilis

Prevalence.—The incidence of syphilis in India is not high at all in spite of published statements to the contrary.

The root cause of the misconception appears to have been the WR positive rate of unselected population. The rate has been found to be as high as 20 to 22 per cent (Iyengar, 1919; Lloyd, Napier and Mitra, 1930). This was due partly to the technique not adapted to the Indian conditions, partly to a lack of a follow-up of the cases and partly, of course, to an implicit faith in the interpretation of the WR given by the European workers of the early days of the WR, based on their experience in Europe. When the defects are eliminated the rate falls to 5 per cent in towns (Grevall and Sen, 1942). In the countryside which is real India it must be much lower. Even in the U.S.A. where 'ten million Americans have it' (Becker, 1937) the disease flourishes mostly in towns and specially in 'boom towns' (Becker and Obermayer, 1947).

That diseases other than syphilis are responsible for a positive WR ('false positive' WR) has now been fully recognized. Long lists of such diseases observed in America have appeared in this journal together with a short list of diseases of special importance in India. They appear again with the latest additions elsewhere in this issue (p. 605).

Comparative benignness.—Not only is the disease not as common as it has been thought to be but quite tame also comparatively. Parasyphilis is a rarity. Even cardiovascular syphilis does not appear to kill with the same ruthlessness as in the West. Syphilis as a cause of abortion has been accepted in India by homology with Europe. It does not approach malaria in its effects.

If syphilis were malignant, as it is in Europe, even from small foci in towns, it would have spread to the masses and aided by their poverty and inability to procure adequate treatment could

have wiped them out within a century or so of Vasco da Gama's arrival in India in 1498. It is believed that he brought it to Asia from Europe (Kampmeier, 1946).

The disease does not appear to thrive in India (Grevall, 1944). Similar observations have been made about East Africa (Ogilvie, 1945).

Apart from the lack of malignancy of syphilis or its inability to thrive on Indian soil, the social system of India is against the spread of the disease: nearly everybody of marriageable age is married and the main problem before most Indians is food, not sex.

Treatment.—Short treatment of syphilis with arsenic, several injections a day and massive dose for a few days, is definitely a risky procedure.

Arsenic treatment after arsenical dermatitis has developed and been cured is not believed to be risky by all syphilologists (Lomholt, 1945). Arsenic preparations can be tried again in small doses.

BAL is a definite advance in treating arsenic and other metal dermatites.

Penicillin in syphilis is the greatest advance so far made in the treatment of the disease. Combination of bismuth, malaria and penicillin is likely to be the ultimate treatment, capable of speedy completion, free from risks and applicable to all stages.

A spontaneous cure has been recorded (Kampmeier, *loc. cit.*).

It is being recognized in the West that an elderly patient with nothing more than a positive Wassermann reaction of the blood to show for a lapse in the remote past is to be congratulated, not treated. In India the occasions for such congratulations are multiplied manifold. Overtreatment rather than undertreatment is the danger in most cases undergoing the Western system of anti-syphilis treatment.

Ninth day erythema.—A morbilliform or scarlatiniform erythema occurring 8 to 10 days after the first injection of an organic arsenical preparation has attracted the attention of syphilologists and dermatologists. It is also known as Milian's ninth day erythema. Some do not consider it as the forerunner of the dreaded exfoliative dermatitis of the arsenical treatment (McLachlan, 1947; Andrews, 1946; Sequeira *et al.*, 1947; Roxburgh, 1947). Others recommend caution (Kampmeier, *loc. cit.*; Wiener, 1947) and yet others can see the connection between the two conditions (Lomholt, *loc. cit.*; Becker and Obermayer, *loc. cit.*).

Arsenical dermatitis appears to be caused by trivalent compounds alone. Arsenoxide and tryarsamide may still be used, especially the latter in cases of syphilis of the central nervous system.

Unusual forms of syphilis. 1. *Syphilis d'emblée or cryptogenic syphilis.*—It undoubtedly occurs and the patient who denies history of a chancre is not necessarily prevaricating (Sequeira

et al., *loc. cit.*; Andrews, *loc. cit.*; Kampmeier, *loc. cit.*; Lomholt, *loc. cit.*). Either the primary sore was so inconspicuous that it was missed or the infection occurred into deeper layers of the skin through pricks such as a surgeon inflicts on himself accidentally during an operation. A recipient of syphilitic blood also develops rash without a primary sore.

2. *Extragenital syphilis*.—Such a condition occurring endemically in Asia Minor was reported towards the end of the last century (E. von Düring, quoted by Sequeira *et al.*, *loc. cit.*). It was conveyed by extragenital infection. Genital sores were exceptional. Secondary manifestations occurred in children and tertiary in adults. The majority of the adult patients suffered from severe destruction of bones recalling the grave lues of the sixteenth century in Europe. Bejel reported recently from the Upper Euphrates Valley, and *Firjal* and *Loath* reported from Iraq and Palestine appear to be the same condition. It is agreed that these diseases are not yaws, but the position is certainly intriguing. It is not unlikely that originally the four causal organisms of syphilis, yaws, pinta and bejel developed from a common source, 'but it seems more probable that Bejel was historically the earliest of the treponematoses, from which these other diseases evolved' (Senekjic, 1946).

Pinta is a contagious disease characterized by papulosquamous eruptions and pigmentary disturbances. It is caused by *Treponema carateum* and is confined to the tropical countries of the Western hemisphere.

[Incidentally, the treponema appears to have five other names: (1) *T. herringtoni*, (2) *T. pector*, (3) *T. americana*, (4) *T. pental*, and (5) *T. dichromoderma*. It is indistinguishable from *T. pallidum* under the microscope—Wiener, *loc. cit.*]

The extragenital lesion of the ordinary variety of syphilis is estimated at 5 to 10 per cent. The usual sites are the lips, tongue, tonsils, female breast, index finger and anus. When there is a rash accompanied not by a sore on the penis but by enlargement of the outermost inguinal glands on one side only, the anus should be suspected strongly and examined carefully.

Details of sites and frequencies, according to several authors, are given elsewhere in this issue (p. 636).

3. *Syphilis ignorée*.—An insignificant, neglected, remote and forgotten episode may produce a lesion of tertiary syphilis. Such are not rare in women (Lomholt, *loc. cit.*).

4. *Chancre redux*.—This lesion has been believed to be a guinea occurring on the site of a chancre (Roxburgh, *loc. cit.*). Recent workers have called such a lesion pseudochancre redux.

The original name is now applied to a recurrent chancre which is simply a chancre which has become active again, due to inadequacy of treatment, etc. The spirochaetes start multiplying again and the lymphatic glands of the region

enlarge once more. This can occur up to 2 years after the infection.

Chancre redux must be taken into consideration in deciding whether fresh infection has occurred in a treated case. The chancre of the fresh infection must not be (i) on the old site or (ii) in an area drained by the previously enlarged lymph glands.

5. *Syphilophobia*.—This mental state is a real danger and has been dealt with elsewhere in this issue (Blood Test Obsession, p. 607).

The spirochaete.—This time-honoured term now definitely describes four groups of organisms spiral in shape: (1) spirochaeta containing an axial fibre round which the body of the organism is coiled in a spiral manner, (2) cristospira possessing a membranous crista in addition to the coils, (3) treponema possessing only a spiral body but neither an axial fibre nor a crista, and (4) leptospira possessing a large number of closely wound turns in its spiral body. The causal organism of syphilis is *Treponema pallidum*. The old name, *Spirochaeta pallida*, although permissible, may not be used.

For microscopy a direct film from a lesion from an area where all sorts of spirochaetes may be found is not so satisfactory as the one made from material aspirated from a lymph gland of the area.

Electron microscope has added to our knowledge of the structure of the spirochaete. It has flagellae at the ends and shows evidence of dividing transversally in multiplying. The coils disappear during the preparation of the specimen for the microscope in drying.

Therapeutic paradox.—This term is applied to deformity consequent on excessive scarring which is in its turn consequent on excessive fibrosis occurring in the healing of a lesion of late syphilis under treatment. Herxheimer reaction increases the inflammation and tissue destruction which heal by more fibrosis than what would have been necessary otherwise (Kampmeier, *loc. cit.*). All cases with suspected inflammatory foci in vital organs should, therefore, be treated with bismuth and iodides before trying arsenic. The former cause less reaction than the latter. This precaution may be applied also to penicillin which is capable of causing a reaction. Cases of cardiovascular, visceral and neuro-syphilis need special consideration.

Gonorrhœa

Gonorrhœa also is a comparatively mild disease. Its usual complications were not very frequent in India even before the introduction of the sulphonamides and penicillin. One knew of husbands who got over the disease and raised large families. A day set aside for weekly passage of bougies was never a feature of big hospitals in India. Arthritis was seen but was not common enough to provide positive sera for use as controls in complement-fixation tests in a

big city like Calcutta. The use of streptomycin may, in future, leave no patient uncured as cases not responding to penicillin (after the failure of sulphonamides) are stated to respond to it. Further, streptomycin, unlike penicillin, is not supposed to mask syphilis (*vide infra*).

Soft sore

Very little original work has been done on this disease in India. Mistaken diagnosis of syphilis, in addition to that of soft sore, because of a hubonulus appearing later is more than likely. The latter complication is not well known. It results from a back flow from a bubo and produces a second ulcer on the penis several weeks after the first. Hence the diagnosis of syphilis on a perfunctory examination.

Further, little work in India is available on the recent finding that a female giving the disease may not show any lesions: the organism lives as a saprophyte in her.

Is a similar state of things possible in syphilis? Even when due regard is paid to the anatomical difficulties, the primary sore is not so easy to find in the female as in the male. Moreover, the female on the whole suffers less from syphilis, being protected, probably, by her hormone and monthly alterations in her biochemistry. Every pregnancy helps her in her cure when she is infected. In experimental syphilis male rabbits are easier to infect than female ones.

Very little testing has been done with the killed Ducrey's bacillus (Reinstierna's intradermal test) although a preparation, Dmeicos, has been available for some time.

There is an immunological reciprocity between this disease and the next disease (lymphogranuloma inguinale). Cases of the latter react with the specific antigen of the former and those of the former react with the specific antigen of the latter.

Ducrey's bacillus is sensitive to streptomycin. This should facilitate the treatment of cases not tolerating or resisting sulphonamide. Unlike penicillin, streptomycin does not mask syphilis which might have been acquired at the same time (McElligott, 1947) as has been stated above. This, however, has been doubted in view of experimental work on animals.

Lymphogranuloma inguinale

The disease is diagnosed very rarely although it occurs in India undoubtedly. Further, the main complication of the disease is its nomenclature. Recognized synonyms are: (i) climatic bubo, (ii) lymphopathia venereum, (iii) poradenitis (Wilson and Miles, 1946), and (iv) tropical bubo (Lomholt, *loc. cit.*). It is also called, loosely, lymphogranuloma venereum (Tobias, 1945) and, incorrectly, even granuloma venereum. Lymphogranuloma inguinale is to be preferred to the rest. The infecting agent is a virus which can be grown on egg membrane. The latest

Frei's antigen is artificially grown, not a dilution of pus from buboes.

Systemic infection with the virus.—Such an infection has been considered as a possible cause of arterial diseases like arteriosclerosis, thromboangiitis, temporal arteritis, giant-cell arteritis and periarteritis nodosa. Mass skin testing with the Frei antigen indicates that the infection is widespread and may occur without apparent lymphadenopathy. It should be thought of in various vascular disorders particularly in young adults (Davies, 1947). Lest these suggestions be taken more seriously than they really deserve it should be stated that recently periarteritis nodosa has been linked to severe allergic disturbances such as occur in asthma, serum sickness, drug allergy, and rheumatic fever (Alexander, 1947).

Congenital lymphogranulomatosis.—Human cases have been found positive by the Frei test and this possibility entertained. Experimentally the disease has been known to pass the placenta in the mouse (Davies, *loc. cit.*).

Serological diagnosis. (1) *Reciprocity with soft sore in skin tests.*—This has already been mentioned.

(2) *Persistence of skin reaction.*—This reaction lasts much longer than the local lesion. This fact is in favour of a systemic infection like syphilis reaction of which also lasts longer than the lesions.

(3) *Complement fixation with Frei antigen.*—This is not satisfactory. The following interfere: (i) psittacosis, (ii) syphilis, (iii) meningopneumonitis, (iv) trachoma, (v) virus pneumonia, and (vi) inclusion hemorrhage (Wadsworth, 1947).

Granuloma venereum

Its recognized synonyms are: (i) granuloma inguinale (Wilson and Miles, *loc. cit.*), (ii) granuloma venereum inguinale (Lomholt, *loc. cit.*), (iii) granuloma ulcerative, (iv) ulcerative granuloma of the genito-inguinal regions, (v) tropical granuloma, (vi) chronic venereal sores, and (vii) serpiginous ulceration of the groin (Rajan, 1937). Granuloma venereum is to be preferred to the rest. The infecting agent is *Donovania granulomatis*, resembling bacilli of the Friedlander group and needing unique growth requirements (Wilson and Miles, *loc. cit.*).

Non-venereal diseases involving genitals

Such diseases undoubtedly exist and are likely to be mistaken for venereal diseases.

Ulcus vulvae acutum and ulcus insons puellarum.—As described in Europe they are probably the same disease and occur in females, mostly children. *Bacillus crassus* has been demonstrated in some cases to be the cause. The lesions appear as small superficial crust-covered ulcers with sharp edges usually on the labia. Occasionally fever and swelling of the inguinal glands are present. Prognosis is good.

Differentiation from venereal disease must be made.

In contrast with this disease, the soft sore affects males, leaving at least some females free.

Reiter's disease (Reiter's syndrome).—A virus disease first described about 30 years ago has attracted attention recently. Indian cases have also been described. Urethritis, pyrexia, cachexia, arthritis, conjunctivitis, iritis and keratoderma are found associated in various combination. The pus from urethra is free from gonococci. The skin lesion, *Keratoderma blennorrhagica*, in this disease and gonorrhœa appears to be one and the same condition and probably always due to the virus which is associated with gonorrhœa at times (McLachlan, *loc. cit.*).

The skin lesion usually confined to soles and palms may occur anywhere as rupia-like crusts.

Behcet's disease (or Behcet's triple syndrome).—This disease has been observed in the U.S.A. Ulceration of the genitals, aphthous lesions of the mouth and uveitis or iridocyclitis occur. Both eyes are eventually involved and lead to blindness. The eye may be attacked later than the genitals and the mouth. Other associated lesions are erythema nodosum, erythema multiform-like condition, acneiform eruptions, papulopustular eruptions, carbuncle-like pyoderma, sub-lingual abscesses, hydrops of knee joint, cerebral symptoms and a marked sensitivity to the various skin tests. Recently a case has been diagnosed in England (Thomas, 1947).

Stevens-Johnson syndrome (Stevens-Johnson disease).—This variety of erythema multiforme exudativum (Andrews, *loc. cit.*) when involving mucous membranes may be mistaken both for syphilis and gonorrhœa. Recently, cases have been described in England with purulent discharge from urethra and conjunctivitis (Nellun, 1947; Murray, 1947). Penicillin has proved useful.

Verruca acuminata.—This condition commonly known as venereal warts and probably caused by a virus is often found associated with gonorrhœa and trichomonas infection. It is known as condyloma acuminatum which of course has nothing to do with the condyloma latum of syphilis. In the female they are usually limited to the vulva but may occur in the vagina or on the cervix. In the male they occur usually on the glans penis, coronal sulcus and inner surface of the prepuce, but occasionally intra-urethrally.

Balano-posthitis.—The condition is an inflammation of the surface of the glans penis (balanitis) and of the inner surface of the prepuce (posthitis). It may occur from many causes and produce several semblances of venereal diseases and neoplasms. It is frequently associated with phimosis.

Trichomonas infection.—It occurs usually in the female and occasionally in the male. Extension upwards is possible. The infection also hides and protracts gonorrhœa. The diagnosis is made by the microscope and the treatment may be long.

Inclusion blennorrhœa.—The condition is also known as inclusion conjunctivitis and swimming pool conjunctivitis (Hyman, 1947). It is caused by a virus similar to the one found in trachoma. The virus probably occurs in the urethra in the male and in the cervix in the female. The conjunctivitis is most marked in the lower lid and is cured by sulpha drugs locally, in ointment, and by the mouth. Diagnosis is made by finding the inclusion bodies and by the clinical course.

Herpes.—This disease must be mentioned as spirochaetes (other than *J. pallidum*) may be found in it, near the genitals.

On the other hand, the primary lesion of lymphogranuloma inguinale may look like herpes.

Special Article

CHIEF LEGAL ASPECTS OF THE VENEREAL DISEASES

By SARDAR SAHIB R. S. GREWAL, M.B.E., M.A., LL.M. (Delhi), F.R.F.P.S. (Glasgow), L.M.S. (Singapore).
Barrister-at-Law of Middle Temple
Civil Surgeon, Mandalay (Burma)

THE following are the main legal aspects of the venereal diseases in which a medical practitioner may be called upon to express an opinion :

1. Implanting of venereal disease in cases of rape.
2. Divorce or dissolution of marriage.
3. Nullity of marriage.
4. Cruelty.
5. Libel and slander.
6. Rules of evidence and professional secrecy.

Implanting of venereal disease in cases of rape

Every medical practitioner or rather more so medical men in Government service are very frequently called upon during the course of their medico-legal work to examine cases of rape. In these cases generally the victim is produced and in some cases the accused also. In addition to other examination for violence, etc., one of the main points in the examination is to look out for venereal disease. If the accused has been suffering from gonorrhœa or syphilis he is likely to infect the victim more especially if the victim is a young girl, as the mucous membranes in the young children are very susceptible to infection. Therefore a careful search should be made for gonococci in the urethral canal and vagina. Urethra should be massaged if necessary and

history of the burning and pain during micturition enquired into. Slide smears should be taken, stained and examined.

Following rules will help as a guide :—

(a) There will be no organism if the patient is examined during the period of incubation.

(b) If the woman is suffering from profuse discharge at the time of examination it is evident that infection must have taken place some time back.

(c) In case of soft sore there is possibility of infection recently.

I have seen many young children suffering from acute gonorrhœa in my medico-legal work.

The victim is usually brought sometimes after the occurrence of crime owing to delay caused in giving First Information Report and the usual procedure to bring the victim before the court and getting consent for medical examination. Therefore by that time if the case is a genuine one and of recent infection early signs and symptoms of gonorrhœa are likely to be present.

Divorce or dissolution of marriage

The relevant section of the Matrimonial Causes Act 1937 is section 7 (1) (e) which reads : 'That the respondent was at the time of the marriage suffering from a venereal disease in a communicable form'. The venereal disease includes gonorrhœa, syphilis and soft sore but *not* venereal itch.

The provisions in the Parsi Marriage and Divorce Act 1936 are section 32 (c).

'That the defendant has infected the plaintiff with venereal disease'.

Divorce is often sought by the wife on the ground that the husband has contracted virulent venereal disease *long after* the marriage. Long after the marriage is important as it proves adultery or at least goes in favour of adultery which is the main ground of divorce. This does not occur in recent infection because a recent infection might be, that is to say soon after the marriage, an act of misconduct prior to marriage or anti-nuptial irregularities indulged in sexual matters. Recent in these cases would mean within the incubation period of the venereal disease.

Reference :

Gleen v. Gleen (1900), 17 T.L.R. 62
and

Anthony v. Anthony, 35 T.L.R. 559

Nullity of marriage

Venereal disease may be a ground for nullity of marriage for the simple reason that the party suffered from virulent communicable disease and marriage has never been consummated at all.

Cruelty

Legally speaking cruelty includes much more than physical violence such as beating. It includes the communication of venereal disease.

Therefore if it can be judged from the circumstances that the husband intended to communicate venereal disease it will be a very good ground for divorce on the ground of cruelty.

Reference :

Collet v. Collet (1828), 1 Curt EC 678.
and

Brendra v. Hemlata (1921), 48 Cal. 283

Finally it should be remembered that it amounts to cruelty if the husband has connection with his wife against her will, when suffering from venereal disease.

There are many debatable points and lines of argument for which the reader should refer to bigger books and authorities like Lord Riddle, Cruickshank and others.

Libel and slander

A medical man is not exempt from an action of libel. It is a matter of common practice for an employer of Insurance Co. to enquire about the presence or otherwise to the venereal disease or in the case of an employment of a servant. In these cases he is generally well protected by the qualified privilege. A qualified privilege may be defined as one in which the parties have mutual interest. Mutual interest on the part of the medical man is usually his moral or other professional obligation and on the part of the employer or master his personal interest. Therefore if he acts in a *bona fide* manner he is safe but if it can be proved that he gave the opinion out of sheer malice then he may have to pay heavy damages as in the case of

Kiston v. Playfair, 1896, The Times, March 28

[Due to the limit on the size of the journal some contributions received for this number could not be included. They will follow in a subsequent issue.—Editor, I.M.G.]

In cases of slander the English law is that any spoken imputing of a person suffering from contagious disease which includes venereal disease to another is actionable *per se* that is to say at all events it is actionable without proof of damage.

Rules of evidence and professional secrecy

The usual rule regarding the compellability of medical witness to testify facts is that he is not protected. He can be compelled to testify to facts. It was decided in

Garner v. Garner (1920), 36 T.L.R. 196

that the medical witness is compellable to testify to the facts of venereal disease in a patient whom he treated.

Professional secrecy

In U.S.A. to divulge a secret received during the course of professional relationship is an offence. In Australian State of Victoria, professional secrets are protected. In England there is no such protection. In Garner v. Garner (1920), 36 T.L.R. 196, the provisions of the Public Health (Venereal Act) Regulations 1917 S.R.O. were overridden by Macardie, J. and compelled the medical witness to divulge the patient's condition at the time of treatment in venereal case and remarked that in a Court of Justice higher considerations arose than that by which a medical man was bound to his patient with respect to professional secrecy. Section 126 of the Indian Evidence Act gives protection to barristers, vakils, etc., but not to the doctors.

MARRIAGE HYGIENE (SECOND SERIES)

(Published quarterly from Whiteaway Building, Hornby Road, Bombay. Editor-in-Chief, A. P. Pillay, O.B.E., M.B., B.S. Subscription Rs. 2-12, single copy Rs. 3-8)

THE first issue of the first series of *Marriage Hygiene* appeared in August 1934 and the last issue in August 1937. The first issue of the second series, dated August 1947, has just been received.

The objects of this journal are : 1. To secure for the subject of sex its proper place in medical and social science by emphasizing its significance and interactions on personal, marital, and social life. Sterility, sex anomaly, sex delinquency, contraception and other allied subjects will not be neglected. 2. To promote the study, clinical as well as research, of sex and sex problems and encourage medical men, psychologists, lawyers,

social workers, and others interested. 3. To educate the public by publishing scientific contributions on the manifold aspects of sex, as it is now recognized that ignorance of biological facts is the prime factor in the alarmingly increasing sex inefficiency, marital maladjustment and family disruption. 4. To encourage the foundation of sex and marriage consultation clinics in various parts of the world and to co-ordinate the interests of those already existing.

The present issue contains original communications on 'Frigidity, misconceptions and facts' by Edmund Bergler, 'The martyrdom of man in sex' by Anthony Ludovici, 'The Hulmer test in sterility' by Max Hulmer, 'Modern insight on incest' by Marc Lanval, and 'Disorders of erection' by J. Lowenstein and sections entitled 'Notes and comments', 'Lives of great men' (series), 'All too human' (series), 'Neurology' and 'Reports, reprints and reviews'.

Penicillin in Treatment of Infantile Congenital Syphilis

(Reprinted from *Medical Newsletter* No. W-449, dated May 1947, prepared by the American Medical Association)

THIS report is based on an analysis of 191 infants under two years of age with manifest congenital syphilis treated by university groups at New Orleans, Philadelphia, Baltimore, and Galveston. The total dosages employed for effective treatment have varied from 20,000 up to 150,000 units per kilogram of body weight among infants for whom adequate observations have been made. It is recommended that dosage schedules in excess of 40,000 units per kilogram be used, and that treatment continue for 60 or more equal intramuscular injections given at three-hour intervals. Schedules comprising 80,000 or more units per kilogram, divided into 120 equal intramuscular injections given every three hours night and day for a period of 15 days, have not yet been evaluated.

Reactions to therapy have appeared unimportant, and we have seen no justification for gradually increasing dosage at the outset of a projected course to avoid these. Only a relatively small number of infants will demonstrate seronegativity during or soon after a single course of penicillin. The number of patients becoming seronegative increases with each month of observation for at least 18 months. Careful periodic examinations are necessary to recognize the small number of serologic and clinical relapses which will require additional therapy. Deaths among infants included in this series do not appear to be related to the use of penicillin or to therapeutic shock.

The authors conclude that although the best method for its use has not been defined, penicillin appears to be the best single agent for the treatment of infantile congenital syphilis. Final evaluation of the efficacy of penicillin in congenital syphilis must await trial of additional schedules of treatment and methods of administering the drug, as well as clarification of the relative spirochæticidal and spirochætostatic action of its constituent fractions.

In a note written after this paper had been completed the authors state that because of the changing character of penicillin mixtures they recommend a total dosage of at least 100,000 units of penicillin per kilogram of body weight, divided into approximately 120 equal intramuscular injections, given at intervals of no longer than three hours 'around the clock' for a period of 12 to 15 days. (Platou, R. V. *et al.* Effect of Penicillin in the Treatment of Infantile Congenital Syphilis. *Am. J. Dis. Child.*, 72, 635, December 1946.)

Studies on Lymphogranuloma Venereum Complement-Fixing Antigens

By CLARA NIGG,
MAURICE R. HILLMAN
and
BETTY M. BOWSER

(Abstracted from *The Journal of Immunology*, Vol. 53, No. 3, p. 259, July 1946)

IN an attempt by one of the authors (Nigg) to find a suitable preservative for lymphogranuloma venereum complement-fixing antigens, phenol was added to a 10 per cent suspension of infected yolk sacs to give a final concentration of 0.25 per cent. The phenolized sample which had been stored at 37°C., instead of showing deterioration as was expected, was four times as active as the control and the two samples kept at lower temperature were twice as active.

A study of the conditions which determine phenolic enhancement is the subject of this paper.

Materials and methods

Yolk sac suspension.—Six-day-old chick embryos were inoculated into the yolk sac with a suspension of lymphogranuloma venereum (LV) virus (Johns Hopkins strain) so standardized that the majority of the embryos died between the sixth and eighth days after inoculation. The yolk sacs were harvested soon after death of the embryos and stored in Lusteroid tubes in a dry ice cabinet. Twenty per cent saline suspensions were prepared from heavily infected frozen membranes by homogenizing in a Waring blender for three to five minutes. To phenolize the suspensions, saline and phenol were subsequently added to make 10 per cent suspensions containing 0.5 per cent phenol. Urea in a final concentration of 2 per cent was usually added to the unphenolized 20 per cent suspensions to inactivate the virus. Suspensions similarly prepared from normal yolk sacs of approximately the same age served as control material in all experiments. The pH of the suspensions usually varied from 6.2 to 6.8. All antigens were bacteriologically sterile.

Antigen standard.—A unit of the antigen was arbitrarily defined as 0.2 ml. of the highest dilution which gave complete fixation with 0.2 ml. of a 1 to 5 dilution of the weakest of these LV serums. This antigen gave no reaction in any dilution tested with normal serums.

Serum standard.—The pooled serums from several clinical cases of LV with positive skin reactions and negative Wassermann reactions were used as stock serum standard. A unit of this serum was defined as 0.2 ml. of the highest dilution which gave complete fixation with 0.2 ml. (1 unit) of the antigen standard. In no case did the serums used in these studies react with antigens prepared from normal yolk sacs.

Titration of antigens.—To 0.2 ml. of 2-fold serial dilutions of the various antigens were

added 0.2 ml. (2 units) of frozen guinea-pig complement and 0.2 ml. (2 units) of standard LV serum in the order stated. Following incubation at 37°C. in the water bath for 1½ hours, one unit (0.4 ml.) of sensitized sheep red blood cell suspension was added and the tests incubated further for ½ hour. Appropriate controls for each reagent were included. Antigen titre was defined as 0.2 ml. of the highest dilution showing complete fixation.

Experimental

There was little or no enhancement when the phenol was added immediately after the suspensions were prepared and subsequently incubated at 4°C. If, however, the phenol was added immediately and the phenolized suspensions subsequently incubated at 37°C. three of five antigens showed 10 to 16-fold enhancement. The antigens that showed marked enhancement did so after 22 to 60 days' incubation at the same temperature.

All of five preparations which had autolysed for 33 to 45 days at 4°C. before addition of phenol and were subsequently incubated at 37°C. for approximately one month showed at least 4-fold enhancement.

The last two phenolized antigens prepared in this study were both phenolized immediately after the suspensions were made and placed at once at 37°C. Both showed 16-fold enhancement. One of these had been kept at 37°C. after phenolization for 22 days (and subsequently stored in the refrigerator) and the other for 34 days. The authors are of the opinion that such a procedure will induce 8 to 16-fold enhancement quite regularly.

As a rule, phenolic enhancement developed slowly and several weeks were often required to effect maximal enhancement regardless of whether the suspensions had been permitted to autolyse before addition of phenol. The titre of the urea-treated control for suspension (which had been stored in the refrigerator) was 1 to 200 whereas the phenolized fraction finally reached a titre of 1-3,200 after four weeks in the refrigerator. The titre of the phenolized suspension likewise increased from 1-200 to 1-3,200 after three weeks at 37°C. and subsequently storage in the refrigerator.

Antigens treated with phenol in concentrations as high as 5.0 per cent showed essentially the same enhancement as those treated with 0.5 per cent phenol.

These LV complement-fixing antigens prepared from infected yolk sacs were remarkably heat stable.

Boiling and phenolization could induce approximately the same degree of enhancement.

The presence of phenol, whether it had induced enhancement or not, did not interfere with the development of enhancement by boiling. On the other hand, if the full potential enhancement had been induced by phenol, sub-

sequent boiling sometimes caused a drop in titre.

Autoclaving phenolized suspensions also induced enhancement.

A series of experiments to determine the possible rôle of pH showed that there was little or no effect on phenolic enhancement at pH 6.0 to 7.5 under any of the conditions investigated. Suspensions buffered with Na-K phosphate often became anticomplementary especially in the higher pH range. The presence of urea seemed to have no effect on enhancement by phenol.

Discussion

The phenolic enhancement described in this report seemed to involve a complex degradation or disassociative process in which autolytic changes, time, temperature and the concentration of phenol played a part. The autolytic changes were a contributing factor. Apparently the requisite autolytic changes in the presence of phenol took place at 37°C. but not at 4°C. Why some preparations failed to develop phenolic enhancement under conditions which quite regularly induced enhancement in others which were similarly treated is inexplicable in the present state of our knowledge concerning the fundamental mechanism involved. That the potentiality for enhanced activity was not lacking in such preparations was shown by the fact that boiling them resulted in as much as 16-fold enhancement.

The difficulty of elucidating the mechanism is increased by the fact that the suspensions consisted largely of non-virus constituents which varied qualitatively and quantitatively depending on such factors as age of embryo at time of harvest, interval between death of embryo and harvest, etc.

The remarkable stability of LV yolk sac antigens at boiling and even higher temperatures strongly suggests that the active fraction possesses carbohydrate properties.

The possibility that the LV complement-fixing antigen may derive from a protein-polysaccharide-lipid complex is suggested both by its stability and its solubility in ether. Phenol may produce disassociative changes resulting in a greater degree of dispersion, which might explain the increased complement-fixing reactivity. Another possibility which should be considered in attempting to explain the mechanism of enhancement is the inactivation of some inhibiting substance either by phenol or by boiling.

These phenolized or boiled antigens are similar to all other LV complement-fixing antigens which have been described in that they lack specificity since they also react with the serums from cases of psittacosis and ornithosis.

Boiled phenolized antigens possess the following advantages:—

1. Activity is greatly enhanced.
2. Phenol serves as preservative.
3. Phenolized antigens are rarely anticomplementary.

4. They exhibit remarkable stability and remain so for over two years.

Studies on Lymphogranuloma Venereum Complement-Fixing Antigens

By BETTY M. BOWSER

and

CLARA NIGG

(Abstracted from *The Journal of Immunology*, Vol. 53, No. 3, p. 269, July 1946)

A HIGH incidence of positive complement-fixation reactions with syphilitic sera, when tested with lymphogranuloma venereum (LV) elementary body suspensions as antigen, has been reported. To determine whether boiled phenolized antigens prepared from yolk sacs infected with lymphogranuloma venereum virus would show a similar high incidence of positive reactions with syphilitic serums three types of syphilitic serums were studied: (a) unselected positive Wassermann serum, (b) serums from cases of primary and 'early' syphilis, and (c) serums from cases of secondary syphilis.

Of 68 unselected positive Wassermann serums, 35.3 per cent reacted specifically with LV boiled phenolized antigen while 10.3 per cent gave non-specific reactions in that there was fixation with both the specific and control antigens.

Of special interest were the observations that of 27 serums from primary and 'early' syphilis, 77.7 per cent reacted with both the specific and control antigens and of 12 serums from secondary syphilis all but one (91.7 per cent) likewise reacted with both antigens.

It was thus obvious that a serological diagnosis for LV could not be made with most sera from the earlier stages of syphilitic infection when either boiled phenolized antigen or the elementary body antigen was used. Attention was therefore directed toward fractionation of the antigen in the hope of eliminating the non-specific type of reaction described above.

It was previously reported that the relatively clear supernate from phenolized boiled antigens prepared from yolk sacs infected with lymphogranuloma venereum virus gave satisfactory complement-fixation reactions with LV serums. In as much as the coagulable protein was largely removed in the preparation of the boiled supernate-antigen, a very considerable purification was thereby effected. It seemed possible that antigens purified in this way might be devoid of the factors responsible for the non-specific fixation so frequently encountered with serums from early syphilis. Boiled supernate-antigens were therefore compared with whole boiled phenolized antigen in complement-fixation tests with such syphilitic serums as gave the non-specific reactions described above.

Fifteen selected syphilitic serums, all of which gave non-specific reactions with the control boiled phenolized antigen, were tested with

various boiled supernate-antigens. The non-specific reactions encountered with control antigen were entirely eliminated in every case by using these boiled supernate-antigens and their corresponding controls. An unequivocal serological diagnosis of LV would thus seem to be indicated in these 15 patients whose histories showed syphilitic infection.

Phenolized boiled supernate-antigens prepared from yolk sacs infected with lymphogranuloma venereum also gave positive complement-fixation reactions with the serums of patients recovered from psittacosis and ornithosis. These cross reactions emphasize the close antigenic relationship within the psittacosis-lymphogranuloma venereum group of viruses.

Rapid Treatment of Early Syphilis with Penicillin in Beeswax and Oil

By EVAN W. THOMAS, M.D.

SIMEON LANDY, M.D.

and

CORINNE COOPER, M.D.

(Abstracted from the *Journal of Venereal Disease Information*, Vol. 28, February 1947, p. 19)

THE treatment of early infectious syphilis with calcium penicillin in beeswax and peanut oil was started at the Rapid Treatment Centre in Bellevue Hospital in August 1945.

From 1st August, 1945 to 25th July, 1946 a total of 802 patients with early infectious syphilis received 4,800,000 units of penicillin in beeswax and peanut oil in a period of 8 days. One group received two injections of 300,000 units daily, morning and evening, for 8 days. The second group received one injection of 600,000 units daily for 8 days. After some time all patients were given a single daily dose of 600,000 units for eight injections.

Patients with primary and/or secondary syphilis only were treated with this preparation of penicillin. All had darkfield positive lesions except for a few who had serologic relapses following previous antisymphilitic treatment for early infectious syphilis. Of the 802 patients treated, 100 had had previous therapy for early syphilis following which they had been reinjected or relapsed. Of the 100 reinfections or relapses, 28 were retreated because of reinfections or relapses following previous treatment at the centre with penicillin in beeswax and peanut oil.

Reactions to treatment

All injections were given intramuscularly, care having been taken to aspirate after the needle had been plunged into the muscle to avoid injection into the blood stream. There was no instance of embolus following any of the injections.

Of the 802 patients treated, 41 (5.1 per cent) had pain and induration at the site of injections only, 77 (9.6 per cent) had low-grade fever usually developing on the fifth to seventh day of treatment associated with pain and induration at the site of injections, and 9 (1.1 per cent) had urticaria which was also accompanied by low-grade fever. In only two cases were injections stopped before the 8-day treatment was finished. These two patients received injections for 7 days only because of the development of severe urticaria. Usually, however, when urticaria developed, the patient had finished the full treatment. Several of the patients with urticaria had an associated angioneurotic oedema but in no case did this last more than 5 days.

The occurrence of reactions was more frequent during the use of certain allotments of penicillin in beeswax and oil than with others. Though more troublesome to prepare and inject than aqueous solutions of penicillin, the fact that only one injection a day is required more than compensates for these minor difficulties.

Evaluation of treatment

The cases have been divided into four groups : (1) sero-negative primary syphilis, (2) sero-positive primary syphilis, (3) secondary syphilis, (4) reinfection or relapse following previous therapy for early infectious syphilis.

All patients delinquent for more than 3 months prior to the preparation of this paper were counted as lost at the present time for follow-up purposes. A few had become sero-negative prior to becoming delinquent, but in computing percentages the delinquent patients were subtracted from the total number treated in each group.

A number of patients still had positive serologic tests 6 months or more after treatment. The writers believe that most of these patients should not be regarded as treatment failures. Certainly those who had quantitative Kahn tests of 8 or less should not be so classified. This opinion is based on the writers' previous experience with rapid treatment or early syphilis where 2 to 3 years passed before some patients became completely sero-negative.

In the group treated for secondary syphilis 4 patients had Kahn titres of over 16 after the sixth month of follow-up. Two were retreated at the sixth month because of Kahn titres of 64; 2 had Kahn titres of 32 six or more months after treatment. All of these should be counted as definite treatment failures. Eight patients had Kahn titres of 16 when last examined six or more months after treatment. Although we do not accept them as definite failures, their present status is in doubt, and we believe they should be regarded as an indeterminate group. All patients with Kahn titres of 8 or less, six or more months after treatment, should in the writers' opinion be regarded as having a satisfactory status at the time of this report.

Relapses or reinfections

That proportionately fewer patients became sero-negative prior to relapse or reinfection in the secondary syphilitic group than in the sero-positive primary series is explained largely by the fact that patients with secondary syphilis usually require a longer time to become sero-negative following treatment than do patients with sero-positive primary syphilis.

The percentage of relapses or reinfections in the sero-positive primary group and the group with secondary syphilis is practically identical for the same period of observation, 12.6 per cent as compared with 11.0 per cent. The percentage of 6.8 relapses or reinfections in the sero-negative primary group is smaller than in the other three series. They were probably all reinfections.

It is of interest that most relapses or reinfections in all groups occurred during the first 6 months after treatment. It frequently appeared that patients were reinfected by sexual partners whom they had infected. This occurred in spite of educational programmes designed to prevent the occurrence.

Spinal fluid findings

Of the 802 patients treated, 766 had spinal fluid examinations at the time therapy was started. All of those examined in the sero-negative primary group had normal spinal fluids. Only 3 of the patients examined in the sero-positive primary series had abnormal findings of increased cells alone in the spinal fluid. In the series with secondary syphilis 46 of those examined had abnormal spinal fluid findings. Of these, 26 had normal spinal fluids when examined from 3 to 5 months after treatment and 17 have had no subsequent spinal fluid examinations. Of the 3 remaining patients, 1 continued to have increased cells and protein in the spinal fluid 6 months after treatment and had a blood Kahn titre of 32. This patient is one of the 2 to be retreated because of persistently high quantitative Kahn tests. Two patients continued to have abnormal spinal fluid findings and had infectious relapses, at which time their spinal fluid Wassermann tests and colloidal gold curves were strongly positive. Two patients who had normal spinal fluid findings at the time of their first treatment for secondary syphilis relapsed later at which time the spinal fluid findings were abnormal. It is interesting that the percentage of abnormal spinal fluids in the group treated for reinfections or relapses after previous therapy was only 5.2 per cent as compared with 10.5 per cent of the group treated for secondary syphilis.

Comparison of patients treated with one and two injections a day

The differences in results of the two schedules for injecting penicillin in beeswax and oil are not statistically significant. Certainly the data show

no advantage in giving two daily injections rather than one. With the exception of the groups treated for secondary syphilis where the percentages of relapses are almost the same (15.2 and 13.2), the single daily injection appears to have yielded better results than two injections a day. This is probably due to chance rather than to the actual superiority of one daily injection. The percentages of failures in all groups are no worse than with any other type of rapid treatment that the writers have used for a similar period of follow-up.

Romansky (M. J. Romansky and G. E. Rittman, *New England J. Med.*, **233**, 577-582, 1945) has shown that a single injection of 300,000 units of calcium penicillin in beeswax and oil maintains effective levels of penicillin in the blood for about 24 hours, and continues to be excreted in the urine for approximately 3 days. If this is confirmed by subsequent investigations, there is an actual therapeutic advantage in treating syphilis with penicillin in beeswax and oil rather than with aqueous solutions because of the prolonged action of the antibiotic.

Conclusions

The treatment of early infectious syphilis with a single daily injection of 600,000 units of penicillin in beeswax and oil for 8 days has proved unusually satisfactory to date. There is no apparent advantage in giving more than one daily injection of this preparation. Possibly smaller daily doses, if continued for more than 8 days, would prove even more effective, but the writers have no data at present on which to base such a conclusion.

Penicillin in Beeswax and Peanut Oil: A New Preparation which is Fluid at Room Temperature: Absorption and Therapeutic Use

By HAROLD L. HIRSH

HARRY F. DOWLING

JEAN J. VIVINO

and

GEORGINE ROTMAN-KAVKA

(Abstracted from the *Journal of Laboratory and Clinical Medicine*, Vol. 32, No. 1, 1947, p. 34)

A NEW preparation of penicillin (Merck and Co., Inc.) incorporated in peanut oil and beeswax, liquid at room temperature, has been studied to determine its rate of absorption and its therapeutic efficacy.

The intramuscular injection of 1 c.c. containing 300,000 units of penicillin resulted in assayable concentrations of penicillin in the serum for twelve hours in 85 per cent of the patients studied, with measurable concentrations persisting for as long as twenty-one hours in 25 per cent. Following an intramuscular injection

of 2 c.c. containing 600,000 units, detectable concentrations were found in 90 per cent of the subjects at twelve hours and in one-third of the patients for twenty-four hours. An injection of 600,000 units subcutaneously resulted in detectable concentrations of penicillin in the blood for twenty-four hours in all but one of the subjects studied.

It is obvious that any modification of penicillin which will permit injections to be spaced at twelve to twenty-four-hour intervals will be advantageous, particularly in the case of patients with such diseases as subacute bacterial endocarditis or syphilis who have to be treated for long periods of time. Therapy is simplified in infections which require treatment for several days. This method of treatment is ideal also for patients with gonorrhoea since it can be carried out with one injection. The high serum concentrations obtained during the first few hours following injection make it likely that infections caused by organisms which are relatively resistant to penicillin can be treated satisfactorily by proper regulation of the dose and time interval. These advantages have been offset, in the past, by the difficulty inherent in the administration of penicillin in peanut oil and beeswax as prepared by the original Romansky formula. The writers believe that the modified preparation which they have used eliminates this difficulty in administration at the same time retaining all the other advantages of the original preparation.

Twenty-seven patients suffering from various infections were treated with doses varying from 300,000 to 600,000 units once or twice per day. The results were similar to those obtained with the use of other preparations of penicillin in beeswax and oil or with equivalent *per diem* doses of penicillin in aqueous solution.

The preparation was found to be easier to administer than the preparations made according to the original Romansky formula.

The Treatment of Early Syphilis (in Africans) with Penicillin Sodium

By MAJOR G. C. COCHRANE, R.A.M.C.

(Abstracted from the *East African Medical Journal*, Vol. XXIII, No. 9, September 1946)

PENICILLIN therapy in early syphilis requires hospitalization of approximately nine or ten days—including seven and a half days of therapy.

A total of 2,400,000 Oxford units is employed. This consists of sixty intramuscular injections of 40,000 Oxford units every three hours over a period of seven and a half days. Alternate buttock is used—the injections being given into the upper and outer quadrant of the gluteus maximus. A needle 2 to 2½ inches long about 20 gauge is used to make sure that the injection is being given intramuscularly. Treatment

should continue without interruption after its initiation.

No local treatment is applied to the primary sore except perhaps a saline dressing.

In obviously mixed infection (early syphilis and soft sore) sulphonamide cream or powder is used—depending on the size and the depth of the lesion.

The *Treponema pallidum* disappears rapidly from the lesions once penicillin therapy is started. The time varies from six to twenty-four hours—the average time being about fourteen hours. Average stay in hospital is ten days.

The Herxheimer reaction (in Africans) is practically nil—although it is found in this Command that over fifty per cent of Europeans have a Herxheimer reaction within twenty-four hours—and consists of pyrexia alone. Herxheimer reaction in Africans treated with penicillin sodium taken over a period of one year—0.09 per cent. These 0.09 per cent were all cases of secondary syphilis—the pyrexia ranging from 102° to 104° and generally starting from four to five hours after the first injection. The pyrexia subsided within twelve hours and treatment was continued without interruption.

It is interesting to note the serological response of seropositive early syphilis to penicillin sodium.

One hundred and twelve patients were 'followed up' for a period of six months; all the patients had early syphilis (Kahn ++++) and each patient received 2,400,000 units of penicillin.

1. After 1 month in 1.8 per cent of cases the Kahn became negative.

2. After 2 months in 47.5 per cent of cases the Kahn became negative.

3. After 3 months in 56.25 per cent of cases the Kahn became negative.

4. After 4 months in 78 per cent of cases the Kahn became negative.

5. After 5 months in 87 per cent of cases the Kahn became negative.

6. After 6 months in 98 per cent of cases the Kahn became negative.

Eleven cases failed to become negative during this surveillance period and the writer was unable to follow up these owing to releases on age and service grounds.

Chronic Vesiculitis as a Factor in the Production of Non-Gonococcal Urethral Discharges

By C. E. MARSHALL

(Abstracted from the *Medical Journal of Australia*, Vol. 1, 15th June, 1946, p. 846)

APART from gonorrhoea and intraurethral chancre which does occur from time to time the causes of a urethral discharge are legion according to the literature. In Australia it would appear that nearly all cases of non-specific urethral discharge can be attributed to one or more of the

following agencies: (i) filtrable viruses and pleuropneumonia-like organisms; (ii) secondary infection by a non-pathogen following chemical or mechanical insult; (iii) chronic vesiculitis and prostatitis.

The rôle of the filtrable viruses and pleuropneumonia-like organisms in the aetiology of non-gonococcal urethral discharges has been clarified by recent work in Australia; but the relationship between virus urethritis and chronic vesiculitis has not been clearly established. Because of the anatomy of the vesicle it is unlikely that chemotherapy would be of any great benefit in established vesiculitis even if the organism was susceptible to the drug. This is not to say that chemotherapy should not be tried in all cases of urethral discharge because although it has been proved disappointing it does appear to help in a small proportion of cases probably those of bacterial origin.

Apart from virus urethritis it is probable that saprophytes can play a part in the production of a urethral discharge. The male urethra normally harbours from 15 to 30 different strains of bacteria in 20 per cent of cases and these organisms may become pathogenic under various stimuli one of which is inflammation of the prostate and vesicles. The high incidence of chronic vesiculitis in cases of non-gonococcal urethritis is illustrated.

In the first group examined (i) an active urethral discharge was present, (ii) the gonococcal complement-fixation test gave negative results, (iii) macroscopic examination by the glass test was made, and (iv) the condition was a first infection. There were 57 patients in this group of whom 24 produced evidence of infection of the prostate and vesicles whilst 33 were normal.

In the second group examined (i) an active urethral discharge was present, (ii) the gonococcal complement-fixation test was not performed, (iii) a microscopic examination of wet specimens was made, and (iv) the condition was a first infection. There were 25 patients in this group of whom 11 were found to have chronic vesiculitis while 14 were normal.

In the third group (i) the patients were symptomatically cured and the urine was free from shreds, (ii) the gonococcal complement-fixation test was not performed, (iii) macroscopic examination was performed by the glass test, and (iv) the condition was a first infection. There were 27 patients in this group of whom 11 produced macroscopic amounts of pus from the vesicles while 16 were normal.

In the fourth group (i) the patients formed a miscellaneous group of those who were cured and those who had active infections, (ii) the gonococcal complement-fixation test was not performed, (iii) microscopic examination was made of wet specimens, and (iv) the condition was a first infection. There were 23 patients in this group of whom six excreted pus from the prostate and vesicles while 17 were normal.

A persistently positive response to the gonococcal complement-fixation test indicates a gonococcal focus of infection. It is also possible for some of these patients to have suffered from an anterior urethritis which was so mild as to escape notice at the time but which had nevertheless extended backwards to set up an indolent infection of the vesicles. This would then develop over a period of weeks only to manifest itself as a urethral discharge at a later date. The long incubation period of non-specific urethritis which varies from seven days to seven months (in one case) would favour this view. Chronic vesiculitis as a cause of protracted urethral discharge is emphasized.

The main symptom of chronic vesiculitis is usually a slight mucopurulent discharge from the urethra and pain may be present in the perineum radiating along the urethra and back into the rectum. The urine is often hazy in the second glass but may be fairly clear especially if blockage of the ejaculatory ducts results in poor drainage. Epithelial and leucocytic shreds are common. If the urine is clear the prostate and vesicles may be gently massaged; but the absence of enlargement or induration of the vesicles cannot be accepted as proof of the absence of infection. The fluid expressed by massage is caught in a specimen glass containing water. The normal secretion will diffuse through the water slowly as a bluish opalescent haze. Purulent material is yellowish-white and will plummet to the bottom of the glass because of the contained leucocytes. A cast of the vesicle may also be expressed. In the absence of pus macroscopically evident by the glass test a wet slide of the secretion may be prepared for microscopic examination. Any specimen containing more than six leucocytes in a dry high power field is suggestive of chronic vesiculitis and prostatitis. If no expression is obtained by massage it may be necessary to dilate the urethra gradually over a period of weeks with curved metal sounds and repeat the examination. Instrumentation or massage in the presence of turbid urine is dangerous. Irrigation of the anterior and posterior portions of the urethra is not essential if the urine is passed immediately beforehand.

The treatment of chronic vesiculitis is long and tedious and no patient can safely be promised a cure in less than two months. The main features are gradual dilatation of the urethra with curved metal sounds twice a week and the use of Kollmann's curved dilator if necessary. If the meatus is small a meatotomy may have to be performed before the larger sizes of sound can be introduced. This will prevent any unnecessary pain brought about by stretching of the meatus. Massage of the prostate and vesicles is carried out two or three times a week but not more often. The criteria of cure are absence of urethral discharge and shreds from the urine and absence of purulent material from a series of at least three massage specimens.

Penicillin in the Treatment of Gonococcal Infections

(Reprinted from a *Medical Newsletter* dated February 1947 released by The International Press and Publication Division of the U.S. Information Service, Washington)

THE results of treatment of acute gonorrhoea in 21,936 cases collected from the literature up to the end of 1945 were analysed, and some of the factors which may affect the cure rates were noted. Gross cure rates of between 92 and 95 per cent were obtained from the initial course of parenteral penicillin given in the doses most commonly used, namely, between 75,000 and 200,000 units, and these rates were not definitely related to the size of the dose within this range. Within the same dose range, however, there were fairly wide variations in cure rates reported by different observers. A dose of less than 75,000 units gave significantly lower cure rates except, perhaps, when penicillin X was used. There were also lower cure rates with an initial course of 200,000 units or more, but this was probably related to the choice of cases.

There were no important differences in the results obtained with similar doses given in aqueous solutions, by intermittent intramuscular injections or by constant or intermittent intravenous injections or by single intramuscular injections in beeswax-peanut oil or in water-in-oil emulsions. The results obtained with single injections of aqueous solutions, however, were definitely inferior to those obtained with the same number of units given in divided doses. It is possible that full doses of an effective sulphonamide, such as sulphathiazole or sulphadiazine, given for five days and supplemented by a course of 100,000 or 200,000 units of penicillin in divided intramuscular doses may give better results than similar doses of penicillin alone. Sulphonamide resistance of gonococci does not affect their sensitivity to penicillin.

The numbers of patients treated with oral penicillin are too few and the factors involved are too many to permit any final deductions concerning the efficacy of this form of treatment. Present indications are that a minimum oral dose of about 600,000 units or more given in divided doses at least one-half hour before meals may be necessary to achieve results similar to those afforded by the usual parenteral doses. Some focal gonococcal infections, particularly early and mild ones, yield readily to the usual course of treatment for gonorrhoea but severe and chronic ones probably require more prolonged treatment for cure and there may be residual symptoms from the tissue damage already done. Purulent arthritis may require local (intra-articular) injections of penicillin, surgical drainage of focal abscesses may be necessary before a complete cure is obtained.

(Meads, Manson and Finland, Maxwell: *Penicillin in the Treatment of Gonococcal*

Infections : Analysis of the Results Reported in the Literature Through 1945. *Am. J. Syph., Gonorr. and Ven. Dis.*, 30, 586, November 1946.)

Comparison of Response of Gonorrhœa to Sulphathiazole and Penicillin : Analyses of 144 Cases

By I. H. MAUSS

(*Lancet*, Vol. 66, March 1946, p. 65, as abstracted in the *Journal of the American Medical Association*, Vol. 131, 15th June, 1946, p. 635)

MAUSS treated 144 patients with gonorrhœa. Seventy-five patients, 66 women and 9 men, were given a total of 22 gm. of sulphathiazole over a five-day period. The first two doses were of 2 gm. each, given at an interval of 2 hours. Thereafter 1 gm. was given every 4 hours during the day until 22 gm. had been administered. Fifty patients of this group (68 per cent) were rendered negative after a single five-day course of this therapy. Eight required two or more courses, so that a total of 59 patients (77 per cent) were cured. Sixteen patients (13 women and 3 men) remained positive in spite of repeated treatment. Sixty-nine patients (55 women and 14 men) were treated with penicillin. Sixty-six (96 per cent) of them were rendered negative with a single course of penicillin (150,000 to 200,000 units) and on re-treatment with 300,000 units the remaining 3 (4 per cent) were rendered negative, so that 100 per cent were cured. Thirty-three of these patients had been sulphonamide-resistant, and all of them were cured after a single course of penicillin. The follow-up control of the patients treated with sulphathiazole showed that patients given sulphonamides should be observed for a minimum of three months before being considered cured. Many failures in this series would have been missed if observations had been terminated earlier. The number of initial penicillin failures in this series was too small to provide any valid idea as to how long the post-treatment observation should be continued routinely before patients are considered cured.

Steady Progress of Penicillin Development

New Processes to Extract Wonder Drug

By ROSEMARY DENSTON, B.Pharm., Ph.C.

(Reproduced from Release No. 597 dated 16th May, 1947, issued by the United Kingdom Publicity Services, New Delhi)

EVER since the discovery of penicillin by Sir Alexander Fleming in 1929, a steady progress has been maintained in the development of this wonder drug.

The news that the sodium salt of penicillin is now available in crystalline form for use in cases where maximum purity and stability are essential, marks another step forward in the field of medical research.

Penicillin has from the start proved singularly difficult to handle. The crystalline form, for instance, was made, only after many failures, by forming an organic base of the penicillin and then converting this to sodium salt. This process, though known for some two years, has only recently been adopted for mass production. It was, however, a most important discovery. Crystalline Penicillin Glaxo contains at least 90 per cent of penicillin II and the material has exceptional stability.

Paramount Value in Surgery

The advantages of the crystalline penicillin are very marked, especially in brain surgery, for it can be used in extreme concentration without risk of irritation. As permissible dosage increases, the powers of the drug appear sometimes even greater than was at first predicted. There is every reason to think that with the progress of research still more remarkable results in healing will be obtained.

The rôle played by British laboratories was, and remains, part of the penicillin story. By 1941 the paramount value of penicillin, above all in war surgery, was established beyond doubt, but Britain, then under constant threat of invasion, could not undertake large scale development of the drug. Research on mass-production techniques was therefore transferred to the United States.

Unfortunately, however, the submerged culture process, involving huge tanks, though plainly superior to 'jug and bottle' methods, was obviously a long-term policy, whereas the vital need for the drug was now. In 1943, with D-Day already foreshadowed, Glaxo Laboratories, whose research staff had been at work on penicillin problems from an early stage, received instructions from the British Government to obtain the greatest possible immediate output.

Commercial Production

Since 1941 experiments and production had been based on the surface or single unit method, which consisted of growing the mould in a flask, from which, after seven to nine days, the active liquid could be harvested. So far little more than experimental quantities had been made in this way; but in February 1943, by simply multiplying single-flask technique, Glaxo became the first to start production of penicillin on a commercial scale.

During World War II, at least 80 per cent of British penicillin was produced by these laboratories, one factory alone handling 300,000 separate flasks. Though quality was the need, quality with quantity was the aim, and it was not long before an 80 per cent pure product was consistently maintained.

In 1945, a British team of chemists, profiting from considerable experience in the use of the freeze-drying technique for other preparations, adapted and finally perfected this process for

use in the final stage of penicillin production—the drying of the purified substance. Ultimately the whole Glaxo penicillin output was freeze-dried at the main factory. A minor diversion occurred here, when a flying bomb hit the drying plant section, and buried some of the plant. The devastation was considerable, but production was resumed in 24 hours.

Considerable as the success with surface methods had been, deep culture had such obvious advantages over the single-unit technique that early in 1943 a special Fermentation Division of the Company had been formed. With the co-operation of the Ministry of Supply, a site was secured for a new factory to be devoted to the production of penicillin. Building was begun shortly after the war ended, and despite the difficulties of that period, production was begun at the beginning of 1946.

Chemical Structure

British production figures had been mounting steadily, but the advent of, first, the new Glaxo factory at Barnard Castle, a north country mill town, and then the factory of the Distillers' Company at Speke, near Liverpool, made future quantity-supplies assured.

During the rapid progress in the production of penicillin by fermentation, a team of British and American chemists were attempting to discover the exact chemical structure of the drug. This work, it was hoped, would not only help to explain its unique properties, but make possible its synthesis. Research showed that there were at least four penicillins, all with the same basic formula, but with slight variations in the side chain. In England they are known as penicillins I, II, III and IV.

Penicillin I was the form obtained in largest quantity when, as in the first surface culture techniques, entirely synthetic food was provided for the mould. Penicillin II is formed in quantity by both deep and surface culture if the 'food' contains corn-steep liquor—a by-product of the starch industry. Penicillin III occurs in small quantities from all corn-steep liquor methods of manufacture, but since it is not readily soluble in chloroform (a usual method of extraction) it is generally eliminated from the final product. Penicillin IV is formed mainly by deep culture production with the newer mould strains. It seems curiously ineffective therapeutically, probably owing to its rapid destruction by the body.

Fortunately research workers were quick to realize this. Changes were made in the 'foods' and in the processes of extraction, so that now penicillin IV is present in only very small proportions, penicillin II predominating in the final product. Dihydro-Penicillin F is a more recent discovery and probably the forerunner of other penicillins.

High Level of Purity

Even in surface-culture days, British chemists maintained a level of purity between four and

five times that of the standard legally required. At the present time this is 300 units per milligram, and penicillin Glaxo has invariably a strength of at least 1,200 to 1,500. When the international standard was established, and it became desirable that a quantity of standard substance of similar purity should be available in Britain, it was thought at first that there was not enough penicillin of the requisite quality. Glaxo Laboratories, however, were able to provide 30 grammes of material at the necessary purity level, and the actual penicillin now in use as a British standard has a potency of 1,600 units per milligram.

The maintenance of a high standard of control depends to a great extent on assay technique. This is a field in which the British team have done good work. In particular, a most useful modification of the *Staphylococcus aureus* plate method was devised in the Greenford Laboratories. At Barnard Castle, research is progressing steadily.

Meanwhile, chemists and biologists are pushing ahead, seeking for other mould-produced substances which may prove effective against conditions not affected by penicillin. Eventually, science may succeed in harnessing the defence substances of many small organisms for the defence of man—and this on such a scale that even our most stubborn ills will be finally conquered.

Paracolon Bacilli and Their Relation to Urinary Tract Infection

By I. G. SCHAUB

(Abstracted from the *Journal of Laboratory and Clinical Medicine*, Vol. 31, September 1946, p. 958)

PARACOLON BACILLI appear to be aberrant forms of *Escherichia* and *Aerobacter* which differ from the typical coliform organisms in their failure to ferment lactose promptly with acid and gas. Other variations may also occur, so that a large number of culturally different paracolon bacilli may be encountered.

Culturally paracolon bacilli may resemble *Proteus*, *Salmonella*, *Shigella* and *Eberthella*, and are frequently mistaken for members of these genera. They may usually be differentiated biochemically, but in some instances serologic tests are necessary.

In one year, 100 strains of paracolon bacilli were isolated from urine specimens from fifty-seven women patients, representing 3.02 per cent of the total number of urine cultures received in the laboratory during 1945 and 4.3 per cent of the positive cultures.

Fifty-one histories were studied to determine the significance of paracolon bacilli in the female urinary tract. In 50.9 per cent of the cases there were symptoms of pyelitis; in 21.5 per cent, symptoms of cystitis. White blood cells only were found in 5.8 per cent of the

patients, and 21.5 per cent showed no signs or symptoms of urinary tract infection.

In 52.9 per cent of the cases the paracolon bacilli were associated in the urinary tract with either *Escherichia* or *Aerobacter*. If only the instances in which more than one culture was taken are considered, then this association between typical and aberrant coliform bacilli occurred in 87.1 per cent of the cases.

It has been suggested that these paracolon bacilli may, in a number of cases at least, be the result of variation in the urinary tract, that in such cases the original infecting agent was a typical *Escherichia* or *Aerobacter*, and that, under conditions as yet undetermined, variation occurred in these typical coliform organisms with the resultant appearance of paracolon bacilli in urine cultures.

Oral Penicillin Treatment of Gonorrhœa

(Abstracted from the *Urologic and Cutaneous Review*, November 1946, p. 689)

A. COHN, B. A. KORNBLITH, AND I. GRUNSTEIN (*American Journal of Syphilis, Gonorrhœa and Venereal Diseases*, September 1946) report on the results in 111 patients with gonococcal infections treated with oral penicillin. Best results were obtained with a group of 50 patients who received a total amount of 600,000 Oxford units of penicillin in divided doses hourly over a period of seven hours. Treatment failed in four patients in this group.

An assayable amount of penicillin could be detected in the serum for about an hour after the oral administration of 50,000 or 150,000 units.

Because of the four-fold amount necessary to obtain results comparable to parenteral use, oral penicillin does not appear to be the preferable method of treatment of gonorrhœa at the present time.

Chancroid Therapy With and Without Sulphathiazole

(Abstracted from the *Urologic and Cutaneous Review*, November 1946, p. 688)

V. C. HARP, JR. (*American Journal of Syphilis, Gonorrhœa and Venereal Diseases*, July 1946) points out that the cardinal principle in the treatment of chancroid is not to interfere with the diagnosis of syphilis with which chancroid is commonly associated. The second important consideration in the treatment of chancroid is cleanliness.

Sulphathiazole (or sulphadiazine) taken orally in doses of 1 gm. four times daily with an initial dose of 4 gm. is recommended by Army directives. This can be begun immediately since it does not interfere with dark-field examinations

for several days at least with examinations for *Hemophylus ducreyi* in the ulcer. *T. pallidum* and *H. ducreyi* have often been found four days or longer after the patient has started taking sulphathiazole.

In the author's study, 350 cases of chancroid were analysed with regard to the incubation period, the size and character of the penile ulcer, and the incidence and character of the complicating lymphadenitis.

Penicillin must not be used in the treatment of penile ulcers unless a positive diagnosis of syphilis has been made. Most patients will recover rapidly without the use of any specific therapeutic agent. Sulphathiazole almost invariably prevents an ulcer from becoming larger and seems to ensure progressive healing which may be due to control of secondary infection rather than to direct action on *H. ducreyi*. The data indicate, however, that sulphathiazole should be used in the treatment of every patient with chancroid.

Some American Ideas on Venereal Disease Control

By R. R. WILCOX

(Abstracted from the *Bulletin of Hygiene*, March 1947, Vol. 22, p. 184)

WILCOX points out that the four main points in a V.D. control programme are (1) controlling sources of infection; (2) prophylaxis; (3) observation and treatment of contacts and patients; and (4) prevention of default. Education is necessary as a first step.

In New York a certificate of freedom from V.D. is essential before marriage; pregnant women have their bloods tested for syphilis; V.D. is notifiable and treatment is compulsory; and women arrested for prostitution are subject to examination and treatment. Most cities have a V.D. control section and every effort is made to trace contacts. In Chicago, under the well-known Dr. Bundeson, bar-keepers are invited to co-operate and if they do not do so are liable to be put out of business by methods which would hardly be acceptable in Great Britain; prophylaxis is not pressed on the civilian but servicemen on furlough are well provided with 'pro' stations; 4,000 reports of contacts or cases are dealt with monthly. Propaganda is forcefully employed; trams and buses carry such slogans as 'Thousands have V.D. and don't know it. Are you one of them?', 'Don't be an Ostrich—Face the Facts—V.D.', 'Easy to pick up V.D.' A new type of advertisement is the movie juke box which alternates entertainment reels with V.D. control messages; these are provided free and last ten minutes. In addition a quarterly periodical entitled 'V.D. Topics' is published. The list of activities would not be

Effective and Low Dosage Sulphonamide Therapy
with

IRGAFEN

(N₁-3, 4-Dimethylbenzoyl Sulphanilamide)

A well tolerated chemotherapeutic agent with definite action.
Total dosage 30-50% lower than that of other sulphonamides.

Indications :

Pneumonia, meningitis, B. coli infections, strepto- and
staphylococcal infections, dysenteric enterocolitis, etc.

Anaemia

The administration of a good tonic is of first importance in the successful treatment of the various forms of anaemia. Generally accompanied by loss of appetite, this condition responds to the analeptic action of Waterbury's Compound, a preparation made from a formula containing products obtained by the enzymatic action of pancreatic ferments on cod liver oil, livers and spleens, malt extracts and hypophosphites. It is produced in a palatable form and can be administered with every confidence by the practitioner.

MARTIN & HARRIS Ltd.,
Mercantile Buildings, Lall Bazar, Calcutta.

complete without mention of the American Social Hygiene Council which corresponds to the British Social Hygiene Council and the Central Council for Health Education.

Results have on the whole been disappointing. Nevertheless the advice given by Stokes 'We must move against promiscuity rather than, or in addition to, disease' seems particularly apposite.

In spite of all their activities it seems probable that V.D. is more prevalent amongst Americans than among Britons, but it is no less true that Americans are more promiscuous than Britons, at any rate so far as service men are concerned.

Reviews

PENICILLIN THERAPY.—By J. R. Goyal, M.B.B.S. Second Edition. 1947. Published by Medical Review of Reviews, Delhi. Pp. ii plus 177

THE book deals with the subject with too much of details. Findings of numerous workers are given. It would have been better if unnecessary details were omitted.

Action of penicillin on *Sp. pallida* is given concisely. In infants administration of penicillin with milk is a useful plan.

Test of sensitivity of micro-organisms to penicillin, and estimation of penicillin content of blood and exudate are given in a simple way which will be of practical help.

The superiority of sulfa drug over penicillin in meningococcal meningitis and of penicillin over sulfa drug in nephritis has been stressed. Improvement by penicillin in meningovascular syphilis and neurosyphilis with time limit of 120 days for maximum effect in cerebrospinal fluid has also been stressed. Superiority of penicillin in treating pregnant women and in preventing congenital syphilis (by two courses) is brought out and this is a great advance.

The chapter on streptomycin deals with salient features. It is not understood why streptomycin should be injected every 3 hours instead of every 4-6 hours.

A. B. R. C.

VENEREAL DISEASE : ITS PREVENTION AND CONQUEST.—By George Ryley Scott, F.Ph.S. (Eng.), F.Z.S. Publishers : Torchstream Books, London, S.W.19. Revised Edition. 1947. Pp. 80. Price, 3s. 6d.

In this booklet the author gives considerable sound information to the public, and manages to have a few digs at moralists and include a

few points in defence of prostitutes. With the latter themes we do not agree.

Prophylaxis includes all kinds of devices, mechanical and chemical.

The book begins with stressing danger to American troops in England. One wonders whether the inspiration is partly propitiatory. Surely, the incidence of venereal diseases was higher in America than in England before the war.

S. D. S. G.

ESSENTIALS OF SYPHILOLOGY.—By Rudolph H. Kampmeier. Second Edition. 1946. Blackwell Scientific Publications, Ltd., Oxford. Available from Messrs. Macmillan & Co., Ltd., London, W. C. 2. Pp. xvi plus 465 with 87 Illustrations. Price, 25s. net

THIS book is a departure from the usual literature on syphilis. It is written for medical men other than specialists in dermatology and serology. It teaches syphilology boldly, without the conventional restraints: negative WR in secondary syphilis does not occur; provocative test gives no help; a small inoculation of spirochaetes may produce the disease without a chancre (established by animal experiments and cases); treatment is not necessary always and an old man with a history but nothing more than a positive WR is to be congratulated, not treated; and a natural cure is possible. These are the samples of goods the book delivers.

The treatment gives in all details all that is known at present: the conservative treatment for cases physically below par; the fever treatment; the intensive treatment which perhaps has been too intensive in its trial at the Vanderbilt Medical School; the penicillin treatment which of course is still to be weighed (one feels it will not be found wanting); and a combined treatment. Attention has been drawn to the therapeutic paradox and its prevention (scarring in healing may ruin a structure).

The unique features of the book are: (1) Case reports. They, with appropriate pictures and colloquial expression, take the reader, magic carpet wise, to the clinic at Vanderbilt and enable him to hear the author demonstrating. (2) Statistics of the various incidences of syphilis. They have been collected by up-to-date methods and in recent years. Syphilis of the stomach is not a rarity, for instance.

What makes the book specially useful in India is that the author's clinic has collected its material mostly from patients who are either 'indigent or fall into the lowest income levels'. Such are most of our hospital patients in India.

A complete divorce between syphilology and dermatology is typified under annular syphilids (pp. 128-130). The usual distinction from pityriasis rosea is not even mentioned. Perhaps the distinction will save time and reassure the patient. The author's policy, however, is compatible with the omission: he will not call any

rash syphilitic without a serological test which according to him is bound to be positive in secondary syphilis. One agrees. A case of syphilis, however, may develop pityriasis rosea during treatment and may feel disappointed with the treatment. Dermatology cannot be divorced from syphilis conveniently.

The text is remarkably free from errors. The paper could be thinner.

References are plentiful and given, without cutting across the thread of thought, with full titles of the communications.

The book is a notable contribution to the knowledge of syphilology and should be widely read. The price is reasonable.

S. D. S. G.

**MODERN DERMATOLOGY AND SYPHIL-
OLOGY.**—By S. William Becker and
Maximilian E. Obermayer. Second Edition.
1947. J. B. Lippincott Company,
Philadelphia, London and Montreal. Pp.
xxx plus 1017 with 484 Illustrations, many
in colour. Price, £5.10.0

THIS book deals with the two subjects separately instead of including syphilis in dermatology as has been done almost universally, so far, everywhere, at least in works written in English.

Both the items are treated fully. The headings and the 'conference style' contribute in no small measure to the clarity of the exposition.

The description of syphilis runs along the usual lines. On certain topics, however, the authors have slightly divergent views which are duly stressed: (1) Ninth-day erythema caused by the arsenicals used in treatment may be a precursor of the dreaded exfoliative dermatitis. Arsenic must be stopped. (2) Every baby of a mother suspected to be syphilitic may not be put on treatment immediately after birth. (3) Thiosulphate may be really useless in arsenical poisoning due to treatment.

The electron-microscope photograph of the *Spirocheta pallida* is duly given as is done in other books. No adequate explanation, however, is available as to why the coils are almost lost. Incidentally, treponema should be preferred to spirochæta and *Leptospira icteroides* is not the causal organism of yellow fever.

In dermatology more emphasis is laid on personal views: this is usual with dermatologists. Lentigo, for instance, is distinct from freckles and may be looked upon as a serious condition.

The present edition includes tropical diseases which makes the book more useful in India than the previous edition.

Reiter's disease and Behcet's disease are not in the index.

The get-up is disappointing. The paper is too glazed and too thick to lend itself to a durable binding, writing on the margin, or even marking of passages. The index is almost

unreadable by mature men who alone will buy and read a book of this size. The poster-like page glued between pages 946 and 947 is unsightly and inconvenient to negotiate. The weight is over seven pounds. One should like to have in one's book case a copy of this book in a better get-up.

S. D. S. G.

**HANDBOOK OF DIAGNOSIS AND TREAT-
MENT OF VENEREAL DISEASES.**—By
A. E. W. McLachlan. Third Edition. E. &
S. Livingstone Ltd., Edinburgh. Pp. 375.
Price, 15s.

A book handier than this handbook will be difficult to find. In 375 small pages the author has described in a lucid way all that must be known of the venereal diseases. Illustrations are excellent. Most of them are in black and white and some in colour.

Marginal headings save waste of time in introducing the items.

Several non-venereal conditions causing confusion in diagnosis are included.

Some faults usually characteristic of the first edition are still present. Examples: (1) Pages 169-170, a line is out of place. (2) Page 200, from two doses, after the decimal point, a zero is missing. (3) *Trichomonas* 'infestation' should be infection.

Then there are some obscurities. Example: Page 125, para 3, sentence 4; the fact that the disease is not confined to a 'single bone' has no connection with the 'whole circumference of the shaft'.

There is a need for a critical perusal of the script for the next edition.

S. D. S. G.

PENICILLIN IN VENEREAL DISEASES.—
By K. D. Lahiri, M.B., B.S. 1947. Himalaya
Publications, Patna. Pp. 108

THIS booklet mostly contains summaries from articles on the subject in different journals, the names and years of which are given in the text, with no detailed list at the end. The author also adds some of his experiences in practice and the modifications of treatment.

There seems to be too many chapters, some of which could conveniently be amalgamated. The rationale of time-dosage scheme could better be discussed in more detail. There is no reason given as to why an intramuscular injection is better than an intravenous injection; in other words, the importance of sudden high peak of penicillin in blood after an intramuscular injection that can attack the organisms in hiding is not stressed. Rather 'uniform content' (p. 30) as advocated is misleading as it speaks for intravenous injection.

At places mention has been made of special suitability of certain modes of treatment in India without much reason for mentioning India: they are suitable for other parts of the world

also. No mention is made of treatment with 6 lacs of penicillin in oil a day in one shot and of crystallized white penicillin which keeps at room temperature. That the potency of penicillin is not affected in the presence of pus as stated on page 40 requires a proof or the test of time.

The text is obscure in parts and there are some printing mistakes.

A. B. R. C.

CAUSES AND CURE OF STERILITY.—By K. V. Mathew. Published by Health Book Stall, 7, Krishnan Koil Street, George Town, Madras. Page 102. Price, Rs. 3-12

THE book, though small in size, deals in an efficient manner with some practical methods based on the writer's medical experience. The chapter entitled 'Hormones' is particularly useful. Some of the examples cited are instructive. The book will be useful to those for whom it is meant. A few printing mistakes occur.

THE RATIONALE OF MALARIA THERAPY IN LATE LOCALIZED SYPHILIS WITH PARTICULAR REFERENCE TO GENERAL PARALYSIS OF THE INSANE

SIR,—At the discussion following an address read before the Medical Society for the Study of Venereal Diseases, Colonel Burke (1931) remarked that what was needed in modern syphilology was a little more imagination and a little less bowing before tradition and the consecrated teaching of the arid textbook. The present writer quotes these words both as apology and excuse for the following theoretical considerations.

Ironside (1925) after discussing the mechanism of cure and rejecting such theories as high temperatures being inimical to *Sp. pallida*, and antagonism between malaria and syphilis, states 'the true mechanism has probably to do with the specific effect of some protein which the disintegrating malaria parasite delivers into the blood . . . and that the destruction by quinine of large numbers of malaria parasites sets free a considerable quantity of soluble antigen, which provokes, by stimulation of the host's tissues, the formation of immune bodies. It is probable that this immune substance has some prejudicial effect on the spirochæta'.

There are two objections to this theory. Firstly, it has been shown by Simpson and Kendell (1941) that physically induced pyrexia is just as beneficial as malaria. These authors quote Wagner-Jauregg—the father of malaria therapy—as admitting that the treatment of

paralytics with physically induced fever gave a number of full remissions as great or greater than malaria. Secondly, if the formation of these hypothetical immune bodies is harmful to spirochætes in late localized syphilis, why is it not equally beneficial in early generalized forms of the disease?

Simpson (1936) and Simpson and Kendell (*loc. cit.*) stress the importance of high temperatures in destroying spirochætes, but that fever alone cannot kill the spirochætes is evident by the fact that these workers found that in early cases of syphilis, fever actually did more harm than good. They state: 'At the outset of these experiments it was decided to institute control studies to determine the efficacy of fever therapy alone . . . after six patients (with early and secondary syphilis) had been treated solely with a total of 50 hours of fever, it was deemed unwise to continue with this part of the experiment since two of these patients developed clinical relapse' (cutaneous rash).

These paradoxical results—benefit in late localized syphilis and harm in early generalized syphilis—call for an explanation which has not yet been forthcoming.

Localization of disease is a well-known phenomenon demonstrating that pathogenic organisms migrate to weakened or injured tissues. Thus Burrows (1932) cites instances of abscesses developing after hypodermic injections, in cases of typhoid, pneumonia, puerperal sepsis, etc., in which the causative organisms of the original diseases were isolated in pure culture from the abscesses. The readiness with which tuberculosis will attack an injured joint is a similar example of migration to weakened tissues. Syphilis acts in the same way, and Burke (*loc. cit.*) states: 'It would be generally agreed that trauma had a distinct influence in determining the sites of syphilitic processes'.

Now, if local trauma can cause localization of disease it seems probable that general trauma (fever) will cause generalization of a localized disease. This indeed is evident in leprosy, for example, where leprotic fever frequently results in invasion of the blood stream by the bacilli. The following facts support the theory that fever is beneficial in G.P.I. because generalized trauma lures the spirochætes from out of the central nervous system into the body tissues:—

1. Fever may cure G.P.I. but it does not cure the underlying syphilis. The Wassermann reaction of the C.S.F. readily becomes negative after malarial treatment, but with insufficient treatment when patients relapse mentally; C.S.F.'s, without exception, revert to positive. This suggests migration to and from the central nervous system.

2. According to Greenfield (1928) spirochætes disappear quickly from the brain in G.P.I., after malaria. Since the syphilis has not been cured the spirochætes must be elsewhere.

3. With the possible exceptions of penicillin and tryparsamide, chemotherapy by itself is of

no value in G.P.I., but after malaria, chemotherapy by bismuth and arsenicals is of undoubted value. This may be, as has been suggested, because the fever renders blood vessels of the brain more permeable to the drugs; but in view of the disappearance of the spirochætes from the brain, the possibility that the spirochætes have migrated to other tissues of the body where they are more readily assailed by the drugs, seems at least as likely an explanation.

4. Indians very rarely suffer from G.P.I. The view that the Indian strain of syphilis differs from that of other places in being purely viscerotropic cannot seriously be maintained. Europeans acquiring syphilis from an Indian source may develop G.P.I. In addition, the European strain of syphilis must have been frequently introduced into India and *vice versa*. The explanation may well lie, not in differing strains of spirochætes, but in the different communities affected. Generally speaking, the European is a robust person, well nourished; literate; probably a brain worker and one to whom syphilis spells social and moral disaster. His brain, therefore, is the comparatively 'weakened tissue', and accordingly, in a small percentage of cases, the European syphilitic develops G.P.I. With the Indian exactly the reverse holds good. The Indian is of poor physique, undernourished, usually illiterate and generally a manual labourer; malaria, hookworm and a host of other diseases tend to lower his physical vitality. His body is the 'weakened tissue', the spirochæte has no inducement to go elsewhere and, accordingly, the Indian escapes G.P.I.

GONORRHOEAL STRICTURE OF THE MALE URETHRA

SIR,—Cases of urethral stricture are not uncommon in Bengal. A specialist, during his practice, is sure to come across a fairly good number in a year. In Europe, congestive or spasmodic types of stricture are common; but stricture due to organic changes in the urethra is becoming rare. Reasons are obvious. Firstly, average peoples of the West possess good

vitality; secondly, they do not suffer from pseudo-sense of morality, hence they are conscious of the value of early and systematic scientific treatment; thirdly, they are used to drinks which cause natural flush of the urethra; fourthly, climatic effect retards the progress of the disease.

In India, particularly in Bengal, the statistical data are incomplete and therefore misleading. On the strength of the so-called available statistics, no scientific inference about the percentage of stricture urethra cases can be correctly ascertained, which, in my opinion, should neither be exaggerated nor underestimated.

From 1933 to 1946, the old records of the Venereal Department of the Campbell Hospital alone prove that out of a total number of the attending cases suffering from chronic gonorrhœa 7 per cent had stricture. Early cases of stricture with slight symptoms are not included in the above list. Another remarkable feature of the records is that this kind of organic stricture is more confined to poor, illiterate wage earners, less common amongst the literate persons belonging to the poor middle class and least among the rich. Another important fact is noticed that all severe types of stricture had a history of suffering from chronic gonorrhœa over eight years or more, while less serious types of strictures developed five years after the infection of gonorrhœa. Formation of stricture in the urethra, as the records say, seldom takes place before the fifth year. This, I should confess, must not be accepted as axiomatic truth; but it may throw some light on future researches about the period stricture in urethra contaminated with gonococci takes to develop.

Yours, etc.,

BENOY SINHA, M.B.,

Surgeon, Venereal Department, Campbell
Medical School Hospitals, Calcutta

V.D. CAMPAIGN IN CALCUTTA

SIR,—I am sending the following lines to you to register my disapproval of the way in which the present V.D. campaign is being conducted.

1. The institution of the campaign is indeed a mystery. So much so, that at one time the popular belief was that the whole affairs were undertaken for the benefit of the American soldiers. This obviously is untrue.

2. The committee itself is not immune to suspicion. The Government did not invite the members of the medical profession to work in the committee nor was the nomination announced before the campaign was started.

3. The campaign has gone on for the last three years but no scientific reports concerning the disease have yet been published.

4. In a Government campaign like this, the medical profession expects to be enlightened about the latest development in diagnosis and treatment of the disease. Not a word of information regarding these points has been mentioned

in the Government bulletins issued by the Director of Social Hygiene.

5. The press propaganda about the campaign seems to be extravagant causing a waste of public money. This may benefit the educated but the illiterate mass is the least helped by such kind of propaganda. This should be modified and public money should be diverted to improve the scientific aspects of the campaign.

To conclude, I hear that some time back the Imperial Serologist sent a skeleton of a scheme for the V.D. campaign. May I know what is its fate?

Yours, etc.,

M. SARKAR, M.B.,

Councillor, Calcutta Corporation.

Calcutta,

10th October, 1947.

POINTS FROM LETTERS

I. CAPTAIN N. B. DUTT, M.B., I.M.S. (retd.) in a letter draws attention to : (1) The erection of huge signboards painted with multiple colours in prominent places on main roads advising the public to avoid venereal diseases. (2) The indiscriminate advertisements with the face of a pretty woman, a flower and an insect in journals and newspapers which are a waste of public money. Extensive newspaper propaganda, production of films, distribution of printed pamphlets or campaign through social workers may amuse a debauch or a prostitute but no self-respecting infected person however educated or poor will utilize those advantages, with a view to shunning publicity. (3) Ill-equipments of clinics, methods of treatment, want of indoor arrangements for complicated cases, lack of publication of scientific reports, adequate measures to detect freshly imported cases or rounding up of infected persons for sterilization, etc., are the grievances requiring attention for the improvement of the present anti-V.D. campaign. The campaign should be thoroughly reconstructed by a strong committee of eminent specialists.

II. In a letter on 'Combat With the V.D.' Dr. N. K. Nag, M.B., writes as follows :—

Owing to certain social customs, e.g. polygamy, early marriage, no widow re-marriage, purdah system, etc., Europeans have got peculiar conception of low Indian morality. Hence, they think, prevalence of the venereal disease is very high in the country. This is, in my opinion, a wrong idea. At the same time, underestimation of V.D. is equally mistaken. In spite of its three years' career, the present Government campaign against the V.D. has failed to collect reliable statistics of the diseases.

Since last war, the curve of morality in this country has gone down. In big cities and towns, hideous display of sensuous pleasure was witnessed; our rural areas were also not immune

from voluptuous scenes sponsored by foreign soldiers. To add to this, co-education, free association of men with women, cinemas, hotels, etc., have evidently encouraged sex-promiscuity in India, which is undoubtedly a cause for the spread of the diseases.

The present anti-V.D. campaign is the first of its kind launched in this province if not in India. Indeed, we need a strong and ceaseless measure to wage war against the venereal diseases. This is a long-felt want, and both the public and the medical profession welcome it. To maintain our national health or to keep the youth of our country free from the infection of the V.D., the present anti-V.D. campaign deserves adequate support from the Government. Financial difficulty should not be the cause of the abolition of the campaign.

In tracing the genesis of the Government anti-V.D. scheme, the Director of Social Hygiene, who describes himself as 'a medical practitioner of Calcutta with high medical qualifications and considerable experience in venereology', in one of his bulletins has made a statement that 'In 1938, free treatment was first introduced in the Medical College Hospital by the present Director'. This is not true. Both the Calcutta Medical College and the Campbell Medical School Hospitals have been giving free treatment of the V.D. under specialists since long before 1938.

Regarding the advisory committee of the campaign, I take a strong exception to it. The birth of the committee is indeed shrouded in mystery; its selection of members is conspicuous by the absence of specialists or serologists; and its activity is equally obscured from the sight of the public. This committee has so long led an unobtrusive career like an Arab princess in the harem of the secretariat. This committee showed all along an attitude of stoic indifference to the Director, in his commitment of multiple breaches of medical ethics, under the plea of propaganda which indeed caused sensation some time back among the members of the medical profession.

In the defence of V.D. training course, the Director has cast unfair reflection on the teaching of medical institutions and the knowledge of medical practitioners in venereology.

Propaganda and publicity have no doubt educative value, but the scheme adopted by the Director is so wide in nature that it is highly expensive; it has failed to serve the purpose for which it is intended. Only the educated few are benefited; the response from the illiterate is not so satisfactory. This is a waste of public money.

Legislative measures referring to the prohibition of quackery and compulsory treatment of infected persons are sound proposals made by the Director. Abolition of brothels through legislation may be possible but it is not desirable. In the West, brothels have practically disappeared, but prostitutes in private garbs are

freely moving about in night clubs, hotels, cinemas, dancing halls, etc. Sterilization of prostitutes and infected men may be possible by the threat of legislation.

Treatment of the V.D. in the evening is arranged, according to the Director, just to 'suit the convenience of patients'. This is an excuse without justification.

Due to scientific and moral reasons, evening treatment should be discarded. Any allowance to a V.D. patient for his personal sterilization is otherwise an encouragement to sexual indulgence. A V.D. patient should not be a pet boy of the Government. Besides, intravenous injections, in the night, to exhausted patients and their reactions afterwards, should not be ignored. Report of accidents are known to me. Preparation of patients before injection should not be ignored.

With the exception of one or two, the so-called V.D. clinics are not well equipped; they offer no treatment other than injections and distribution of tablets. They work like ablution centres. Venereal departments attached to teaching institution should have facilities for researches.

There is no provision for indoor beds at present.

The attention of the Government may be drawn to the scheme submitted by the Imperial serologist.

III. A communication entitled 'Prevention of the V.D. through social means' has been received from Dr. Benoy Sinha, M.B., Surgeon, Venereal Department, Campbell Medical School Hospitals, Calcutta. Dr. Sinha's summary of this communication is given below :—

1. Indifference of the society due to pseudo-sense of morality is responsible for insidious spread of the venereal diseases.

2. There is no real scientific organized prevention campaign against the venereal diseases, the prevalence of which in India should not be dismissed as a low figure; on the other hand, the mischief in our country due to the V.D. as a post-war problem is considerable.

3. No campaign is worth organizing unless an accurate map of infected areas is drawn up.

4. Susceptibility to sexual temptations rises at the age of puberty and reaches its peak between 25 and 30 years of life. Hence this is the most vulnerable period of life which through home influence, marriage and State protection should be guarded against the danger of infection.

5. Public offices, commercial quarters and industrial centres, if statistics is investigated, actually suffer an annual loss to a great extent on account of sickness among workers due to the sexual diseases.

6. If promiscuous sexual union is controlled, prevalence of the venereal diseases in the society is positively checked.

7. The modern age is extraordinarily crazy over indiscriminate sexual pleasures. With the

advancement of civilization, morality in the society has crossed the limit of decency, and ingenious devices are designed to feed human lusts.

8. Sex in man, as in animals, is an instinct difficult of control at times. Repression or suppression of this powerful instinct through forced celibacy or legal measures is sure to end in tragic failure.

Shameless exploitation of the reproductive organs in commercialized form is widespread which can be reduced to a relatively small volume through moral elevation, improvement of economic condition, and environments, social reformation and positive provisions for good home comforts for all persons belonging to the State.

9. Humanity demands a complete co-ordination of politicians, scientists, eugenicists and social reformers in a fight against the venereal diseases.

This is a war justifying a concentrated joint effort of whole mankind irrespective of races, colours and classes.

10. Teaching of sex psychology and sex hygiene is advisable only to grown-up boys and girls advanced in general or special courses and where co-education is introduced. Children should not, through a direct method, receive education on sex.

Any Questions

SITE OF LESIONS IN PRIMARY SYPHILIS

SIR,—I shall feel grateful if you could enlighten me about the following :—

1. Percentages of cases showing primary chancres on different sites—prepuce, frenum; coronal sulcus and scrotum, penis (shaft, root, glans and meatus), and extra-genital chancres.

2. Any reference from the literature on the subject.

I have got 'Stokes', 'Harison' and 'Lees' with me but none of them gives percentages of cases showing primary lesions in different sites. Reference about primary lesions in women is there all right.

Yours, etc.,
BALBIR SINGH,
MAJOR.

MAIN HOSPITAL,
JAMSHEDPUR.

[The following extracts may be useful :—
DISEASES OF THE SKIN.—By James H. Sequeira, John T. Ingram and Reginald T. Brain. J. & A. Churchill Ltd., London. Fifth edition, 1947. Page 528

Genital chancres in the male occur on the side of the frenum, on the prepuce and glans,

and in the sulcus behind the glans. In rare cases the meatus is the site, and urethral chancres have been observed. Occasionally, the chancre develops on the body of the penis, or on the scrotum, or the skin over the pubes.

Extra-genital chancres may occur anywhere, but are commonest on the face and fingers. Of 50 consecutive cases of extra-genital chancre the sites were—lip, 29 (15 upper, 12 lower, 2 both lips); cheek, 3; nostril, 2; chin, 2; finger, 7; thumb, arm, shoulder, buttock, umbilicus, tongue, tonsil, 1 each. Kissing is the common cause of lip chancres, but in several instances glass-blowers have been infected by the use of a common blowpipe. Infection of the scalp in a barber's shop has been reported by Dr. Walmsley, and Mr. Eardley Holland had a case in an infant whose scalp was infected at birth. Lomholt has reported two similar cases in which forceps injury appears to have been the site of infection. In the buccal cavity, the tongue and the tonsil are most frequently involved. Finger chancres occur about the nails, and the infection is often the result of digital examination by medical men, dentists and midwives. The eyelid is occasionally the site of a chancre, the lesion being attended with much oedema. Vaccinal chancres are now practically unknown. The nipple may be the site of a primary sore, and also the anus.

Extra-genital chancres on the mucous surfaces are usually ulcerative, and the surface of the ulcer is often covered with a greyish membrane resembling that of diphtheria.

We have no reliable figures as to the relative frequency of extra-genital chancres, but estimate it at less than 5 per cent. Of 141 adult males in the London Hospital Clinic, extra-genital infection was known to have occurred in 3.3 per cent. Of 136 adult females, extra-genital infection was known to have occurred in 11 per cent. This proportion is too high, as many women do not show signs of syphilis till the tertiary stage. Finger gave the proportion in several European clinics as follows :—

	Genital	Extra-genital
Austria—		
Males	94	6
Females	86	14
Sweden	84	16
Balkan States	50	50
Czarist Russia—		
Government of Vladimir ..	9	91
" " Rjasan ..	26	74
" " Kursk ..	8	92

ESSENTIALS OF SYPHILOLOGY.—By Rudolph H. Kampmeier. Macmillan & Co., Ltd., London. Second edition, 1946. Page 97

Primary lesions of syphilis in most instances occur on or about the genitals. Some authors estimate that about 95 per cent of chancres are

found about the genitalia. Among the more than six thousand cases on record at the Vanderbilt University Hospital Syphilis Clinic, there were 463 patients with chancre. Of these primary lesions, including those already accompanied by secondary lesions, 25 appeared at sites other than the genitalia. Thus in our cases the incidence of extra-genital chancres was 5.5 per cent. The distribution of extra-genital lesions is shown below :—

	MALES		FEMALES	
	White	Negro	White	Negro
Lip ..	5	3	3	2
Tonsil	1	1
Tongue ..	1

Service Notes

APPOINTMENTS AND TRANSFERS

LIEUTENANT-COLONEL B. N. KHAN, Chief Health Officer, Delhi, is appointed to officiate as Director of Health Services, Delhi, with effect from the afternoon of the 14th August, 1947, *vice* Lieutenant-Colonel D. MacD. Fraser.

Major V. Sivasankaran, Medical Adviser (Pension) (D.A.D.M.S.), Ministry of Defence (Pensions Branch), is appointed Medical Adviser (Pensions) (A.D.M.S.), *vice* Lieutenant-Colonel E. C. Hicks vacated, 23rd August, 1947.

The undermentioned officer of the I.M.S. (E.C.) reverts from the I.A.M.C. and is seconded for service in the Royal Indian Air Force :—

Captain Rama Krishna. Dated 13th March, 1947.

The undermentioned officer has reverted to emergency cadre of I.M.S. on termination of service with the R.I.A.F.

ROYAL INDIAN AIR FORCE (MEDICAL BRANCH)

Flt.-Lieutenant B. S. Khangura. Dated 22nd March, 1947.

LEAVE

Major T. Sommerville, lately Assistant Director, Central Research Institute, Kasauli, is granted combined leave for 2 years and 4 months pending retirement with effect from 16th August, 1947.

PROMOTIONS

Colonel S. S. Sokhey is granted local rank of Major-General whilst holding the appointment of Director, Haffkine Institute, Bombay.

Lieutenant-Colonels to be Colonels

H. M. Strickland. Dated 6th June, 1947.

Sir S. S. Sokhey. Dated 15th December, 1944.

Majors to be Lieutenant-Colonels

6th April, 1946

Major Manohar Nath Hukku. Dated 19th June, 1947.

Ty. Major Veriam Singh Bhattal. Dated 24th June, 1947.

Ty. Major Puliur Krishnaswami Duraiswami. Dated 26th June, 1947.

Ty. Major Abdul Aziz Malik. Dated 26th June, 1947.

Major Nandkishore Ganesh Gadekar. Dated 26th June, 1947.

Major Vadarangam Swaminada Mahadevan. Dated 12th July, 1947.

Major Rustam Cavashah Dorabji Tarapore. Dated 19th July, 1947.

The undermentioned officers are permitted to relinquish their commissions on release from army service and are granted the honorary rank of Major :—

INDIAN LAND FORCES—INDIAN MEDICAL SERVICE
 SECONDED TO THE INDIAN ARMY MEDICAL CORPS
 (Emergency Commissions)

Major Sardari Lal Bhandari. Dated 26th September, 1946.

Major Dhanjishaw Fardunji Mehta. Dated 7th November, 1946.

Ty. Major Pandharangamo Gopalrao Gollerkeri. Dated 8th November, 1946.

Ty. Major Gajanan Dattatray Joglekar. Dated 30th November, 1946.

Major Bhabanidas Bhattacharyya. Dated 2nd December, 1946.

Ty. Major Walter Eugene Owens. Dated 6th December, 1946.

Ty. Major Gopendra Nath Mukherjee. Dated 5th February, 1947.

Major Chandulal Shirolal Tamboli. Dated 5th April, 1947.

Ty. Major Sibabrata Chatterjee. Dated 4th May, 1947.

Ty. Major Sudhansu Kumar Ray. Dated 15th June, 1947.

Major Mahadev Dattatraya Joshi. Dated 5th July, 1947.

Major Balwant Sadashiv Patankar. Dated 5th July, 1947.

The undermentioned officers are permitted to relinquish their commissions on release from army service and are granted the honorary rank of Major :—

INDIAN LAND FORCES—INDIAN MEDICAL SERVICE
SECONDED TO THE INDIAN ARMY MEDICAL CORPS
(Emergency Commissions)

Ty. Major C. T. V. Hemchandran. Dated 28th May, 1947.

Major E. J. Cullen, Medical Adviser (D.A.D.M.S.), Ministry of Defence (Pensions Branch), relinquished the appointment. Dated 25th August, 1947.

The undermentioned officer is permitted to relinquish his commission on reversion to the Indian State Forces :—

INDIAN LAND FORCES—INDIAN MEDICAL SERVICE
SECONDED TO THE INDIAN ARMY MEDICAL CORPS
(Emergency Commission)

Captain Vasant Vinayak Joshi. Dated 13th February, 1946.

The undermentioned officer is permitted to relinquish his commission on release from army service and is granted the honorary rank of Captain. His services are replaced at the disposal of the Government of United Provinces with effect from the date specified :—

INDIAN LAND FORCES—INDIAN MEDICAL SERVICE
SECONDED TO THE INDIAN ARMY MEDICAL CORPS
(Emergency Commission)

Captain A. R. Faruqi. Dated 20th March, 1946.

The undermentioned officer is permitted to relinquish his commission on release from army service and is granted the honorary rank of Captain. His services are replaced at the disposal of the Government of Punjab with effect from the date specified :—

INDIAN LAND FORCES—INDIAN MEDICAL SERVICE
SECONDED TO THE INDIAN ARMY MEDICAL CORPS
(Emergency Commission)

Captain Man Mohan Singh. Dated 19th April, 1946.

The undermentioned officer is permitted to relinquish his commission on release from army service and is granted the honorary rank of Captain. His services have been placed at the disposal of the Government of Mysore with effect from the date specified :—

INDIAN LAND FORCES—INDIAN MEDICAL SERVICE
SECONDED TO THE INDIAN ARMY MEDICAL CORPS
(Emergency Commission)

Captain A. S. Venkatachalam. Dated 27th May, 1946.

The undermentioned officer is permitted to relinquish his commission on release from army service and is granted the honorary rank of Captain. His services are replaced at the disposal of the Government of C.P. and Berar with effect from the date specified :—

INDIAN LAND FORCES—INDIAN MEDICAL SERVICE
SECONDED TO THE INDIAN ARMY MEDICAL CORPS
(Emergency Commission)

Captain M. G. Pendharkar. Dated 9th June, 1946.

The undermentioned officer is permitted to relinquish his commission on transfer to the Royal Army Medical Corps (Regular Army Short Service Commission) with effect from the date specified :—

INDIAN LAND FORCES—INDIAN MEDICAL SERVICE
SECONDED TO THE INDIAN ARMY MEDICAL CORPS
(Emergency Commission)

Captain G. T. Wallace. Dated 4th April, 1947.

The undermentioned officers are permitted to relinquish their commissions on release from army service and are granted the honorary rank of Captain :—

INDIAN LAND FORCES—INDIAN MEDICAL SERVICE
SECONDED TO THE INDIAN ARMY MEDICAL CORPS
(Emergency Commissions)

Captain Radha Syam Saha. Dated 26th April, 1946.

Captain Narayan Sheshgiri Gaitonde. Dated 29th May, 1946.

Captain Harendra Bahadur Sinha. Dated 25th June, 1946.

Captain Ram Krishna Mendireth. Dated 19th November, 1946.

Captain Mohammad Mamtaz-ur Rahman. Dated 12th December, 1946.

Captain Nallepilly Ranganatha Ramkrishnan. Dated 26th January, 1947.

Captain Kala Chand Saha. Dated 3rd February, 1947.

Captain Bhupati Ranjan Mukhopadhyay. Dated 6th April, 1947.

Captain (Mrs.) Elizabeth Mary Pilvang. Dated 20th April, 1947.

Captain Dev Rai Aggarwal. Dated 20th April, 1947.

Captain Syed Abid Ali. Dated 28th April, 1947.

Captain Dalip Kumar Roy Choudhury. Dated 29th April, 1947.

Captain Kamakhya Prasad Mitra. Dated 6th May, 1947.

Captain Sudhir Kumar Nandy. Dated 7th May, 1947.

Captain Azizur Rahman Chowdhury. Dated 14th May, 1947.

Captain Mihir Kumar Mitra. Dated 4th June, 1947.

Captain Kumud Chandra Dhar. Dated 12th June, 1947.

Captain Cottur Muthuswamy Chandrasekaran. Dated 15th June, 1947.

Captain Turuvekere Lakshmiramanaiah Rama Krishna Rao. Dated 20th June, 1947.

Captain Akepati Sivarama Reddy. Dated 22nd June, 1947.

Captain Chalavadi Vankateswarlu. Dated 24th June, 1947.

Captain Shamsheer Bahadur Singh Bawa Bhalla. Dated 26th June, 1947.

Captain Burjore Edulji Pardiwalla. Dated 26th June, 1947.

Captain Amalendu Sen Gupta. Dated 26th June, 1947.

Captain Sant Singh Hamal. Dated 26th June, 1947.

Captain Harbans Singh Jawandra. Dated 4th July, 1947.

Captain Jagadish Chandar. Dated 5th July, 1947.

Captain Brij Nath Bhargava. Dated 6th July, 1947.

Captain Ankes Kumar Chakrabarti. Dated 8th July, 1947.

Captain Altaf Mahmood. Dated 14th July, 1947.

Captain Pathpalli Sarvothamyya. Dated 19th July, 1947.

INDIAN LAND FORCES—INDIAN MEDICAL SERVICE
SECONDED TO THE INDIAN ARMY MEDICAL CORPS
(Emergency Commissions)

(WOMEN'S BRANCH)

Captain (Miss) Lakshmiraju Suryakantham. Dated 27th May, 1946.

Captain (Miss) Tehmina Namdar Irani. Dated 9th July, 1947.

The undermentioned officers are permitted to relinquish their commissions on release from army service and are granted the honorary rank of Captain :—

INDIAN LAND FORCES—INDIAN MEDICAL SERVICE
SECONDED TO THE INDIAN ARMY MEDICAL CORPS
(Emergency Commissions)

Captain Pandurao Motilal Desai. Dated 26th May, 1946.

Captain Yash Deva Wahie. Dated 27th July, 1946.

Captain Obadiah David. Dated 29th October, 1946.

Captain Karkal Ananthram Shetty. Dated 10th December, 1946.

Captain Budihal Raghavendrachar. Dated 21st March, 1947.

Captain Indu Bhusan. Dated 13th August, 1947.

Captain Murari Mohan Som. Dated 16th August, 1947.

Captain Rabindra Nath Sil. Dated 20th August, 1947.

Captain Durga Das Guha Thakurta. Dated 22nd August, 1947.

(WITHIN INDIAN LIMITS)

Captain Mahmud Khan Tukhi. Dated 27th November, 1946.

The undermentioned officers are permitted to relinquish their commissions on release from army service and are granted the honorary rank of Captain :—

INDIAN LAND FORCES—INDIAN MEDICAL SERVICE
SECONDED TO THE INDIAN ARMY MEDICAL CORPS

(Emergency Commissions)

Captain Gagan Chand Ray. Dated 9th June, 1946.

Captain Haran Krishna Mallick. Dated 8th September, 1946.

Captain Janardan Kashinath Gharpure. Dated 24th October, 1946.

Captain Quazi Abul Khair Mohd. Abdul Khaleque. Dated 25th April, 1947.

Captain Carlyle Wilfred Russell D'Rozario. Dated 1st July, 1947.

Captain Shaikat Ali Syed. Dated 6th July, 1946.

Captain Prabhas Chandra Bose. Dated 16th October, 1946.

Captain Gouranga Lal Banerjee. Dated 21st December, 1946.

Captain Shankar Anant Ajgaonkar. Dated 8th January, 1947.

Captain Baji Gnaneshwar Rao. Dated 4th June, 1947.

INDIAN LAND FORCES—INDIAN MEDICAL SERVICE
SECONDED TO THE INDIAN ARMY MEDICAL CORPS

(Emergency Commission)

(WOMEN'S BRANCH)

Captain (Mrs.) Elizabeth Mary Pilvang (*nee* Hugill). Dated 20th April, 1947.

The undermentioned officers are permitted to relinquish their commissions on release from army service and are granted the honorary rank of Captain :—

INDIAN LAND FORCES—INDIAN MEDICAL SERVICE
SECONDED TO THE INDIAN ARMY MEDICAL CORPS

(Emergency Commissions)

Captain Tonda Dayanand Saraswat. Dated 25th July, 1946.

Captain Mani Mohan Bhattacharyya. Dated 27th October, 1946.

Captain Bimal Bikash Biswas. Dated 30th October, 1946.

Captain Rabindra Nath Sen. Dated 30th November, 1946.

Captain William Samuel Raju. Dated 10th December, 1946.

Captain Aricarevula Nageswara Rao. Dated 14th January, 1947.

Captain Apurba Kumar Ghosh. Dated 18th April, 1947.

Captain Dibakar Kundu. Dated 24th April, 1947.

Captain Durga Charan Bhar. Dated 29th April, 1947.

Captain Chittaranjan Ray. Dated 6th May, 1947.

Captain Satya Bhushan Dutta. Dated 12th May, 1947.

Captain Haradhan Chatterjee. Dated 18th May, 1947.

Captain Satya Saran Chatterjee. Dated 3rd June, 1947.

Captain Narendra Sanmukhlal Shroff. Dated 3rd June, 1947.

Captain Kochat Purushothaman. Dated 18th June, 1947.

Captain Jagannath Hari Joshi. Dated 21st June, 1947.

The undermentioned officer is permitted to relinquish his commission on release from army service and is granted the honorary rank of Surgeon-Lieutenant :—

INDIAN LAND FORCES—INDIAN MEDICAL SERVICE
SECONDED TO THE INDIAN ARMY MEDICAL CORPS

(Emergency Commission)

Captain Keshav Shamrao Dharadhar. Dated 14th March, 1947.

The undermentioned officers are permitted to relinquish their commissions on release from army service and are granted the honorary rank of Flight-Lieutenant :—

INDIAN LAND FORCES—INDIAN MEDICAL SERVICE
SECONDED TO THE INDIAN ARMY MEDICAL CORPS

(Emergency Commissions)

Captain Kuruvilla Kurian. Dated 13th August, 1946.
Captain S. P. Chatterjee. Dated 19th September, 1946.

Flight-Lieutenant Hardial Singh Gill. Dated 8th May, 1947.

Captain Oyitti Manakadan Satyendran. Dated 16th May, 1947.

Flight-Lieutenant V. B. Tawdey. Dated 26th June, 1947.

Flight-Lieutenant Srinivasa Rao Kidiyoor. Dated 12th July, 1947.

The undermentioned officers are permitted to relinquish their commissions on release from army service and are granted the honorary rank of Squadron Leader :—

INDIAN LAND FORCES—INDIAN MEDICAL SERVICE
SECONDED TO THE INDIAN ARMY MEDICAL CORPS

(Emergency Commissions)

Major M. U. Hyat. Dated 13th April, 1947.
Ty. Major Maddimsetti Venkataswamy Naidu. Dated 26th June, 1947.

Major (Ex-Squadron Leader) A. K. Basu. Dated 15th July, 1947.

Publishers' Notice

SCIENTIFIC Articles and Notes of interest to the profession in India are solicited. Contributors of Original Articles are entitled to receive 25 reprints *gratis*; additional reprints can be obtained on payment. No reprints will be supplied unless contributors ask for them at the time of submitting their manuscripts.

The preparation of reprints entails rearranging the type, so that there is often a delay of a month or more, after the publication of the *Gazette*, before the reprints are ready. If reprints are not received within two months of publication of the *Gazette*, contributors should write to the Publishers.

Papers and articles forwarded for publication are understood to be offered to *The Indian Medical Gazette* alone, and any breach of this rule will be followed by non-publication. When any such article appears in *The Indian Medical Gazette*, the copyright automatically becomes the joint property of the author or authors and of the publishers.

Communications on Editorial Matters. Articles, Letters and Books for Review should be addressed to THE EDITOR, *The Indian Medical Gazette*, c/o The Calcutta School of Tropical Medicine, Central Avenue, Calcutta.

Communications for the Publishers relating to Subscriptions and Advertisements should be addressed to THE PUBLISHERS, *The Indian Medical Gazette*, P. O. Box No. 54, Calcutta.

Annual Subscription to '*The Indian Medical Gazette*', Rs. 16 including postage, in India. Rs. 19-8 including postage, abroad. Single copies Re. 1-8 each. Back numbers (if available) for the previous year Rs. 2-8 each; and all other back numbers Rs. 5 each.

The Editors of *The Indian Medical Gazette* cannot advise correspondents with regard to prescriptions, diagnosis, etc., nor can they recommend individual practitioners by name, as any such action would constitute a breach of professional etiquette.

PLASTIC SURGERY IN GENERAL PRACTICE

By P. C. SANYAL, M.B., F.R.C.S. (Eng.)

Visiting Surgeon, Medical College Hospital, Calcutta

PLASTIC surgery is known to have been practised in the ancient times of the Vedas but its development as a highly specialized branch of surgery began since the Great War of 1914-18 which is comparatively a recent affair. Plastic surgery demands the highest degree of skill, accuracy of judgment and unlimited patience and is naturally a specialist's job but surgeons in general practice should not give up this branch of surgery altogether as so often a specialist is not available until it is too late. With the modern advancement, many an operation has become safe to the patient and with reasonable care one can give satisfactory relief to those who are physically, mentally and morally maimed. Some commoner conditions requiring such reparative surgery are mentioned here.

BURNS AND CONTRACTURES

This forms the largest group of cases that require attention.

In all extensive burns, the denuded area as soon as it becomes fit should be covered with epidermis graft (Thiersch). This is necessary not only for the economy of suffering but for shortening the period of septic absorption, loss of fluid, chronic suppuration and lardaceous disease. It also prevents the subsequent contracture that might follow. As a matter of fact it is a reproach to surgery to allow hideous contractures after a burn. Where the burnt surface is comparatively extensive, one may have to resort to pinch graft (Riverdin's whole thickness graft) and cover the area in regular rows by these little islets of whole thickness of the skin. The cosmetic result following this is very poor due to the spotted appearance of the grafted area and is, therefore, better avoided in exposed areas, specially in the face. The merit of Thiersch graft lies in its high percentage of success in 'take' but the area grafted becomes darker in hue and shrinking of the epithelium cannot be prevented if there is deeper tissue damage.

In cases of burns where contracture has already been allowed to form, the repair has to be done in many stages and various combinations of techniques have to be undertaken. This taxes the ingenuity of the surgeon and the tolerance of the patient to the utmost limit. The actual process of the operation will vary according to the site and manner of tissue destruction and resulting deformity.

The following are some of the essential points in plastic repair :

1. Accurate assessment of loss of tissue. This is very difficult and requires the help of an artist and models. Unless the surgeon has an accurate idea of tissue loss, he may land himself in the awkward position of producing further deformity instead of removing it.

2. Substitution should be accurate and with tissues morphologically as similar as possible. Thus where whole skin is lost, a graft of the whole skin would naturally give the best result. Similarly, if the area involved is lined with mucosa, the graft should possess the same lining. If this is not possible, it must at least have a lining of the skin epithelium.

Where supporting bony tissue is lost, the graft should contain bone or similar structure such as cartilage to make good the loss. The more uniform the substitution, the better the cosmetic result.

3. Restoration of function may be as important or even more important than the cosmetic appearance.

As in many of these cases the graft has to be taken from a distance, tube pedicle graft in several stages gives the best possible result. As a matter of fact Gilles' tubing of the graft has revolutionized this branch of surgery. By virtue of its continuity of blood supply which is never cut off, 'take' of such a graft is assured. Being made of skin and subcutaneous tissue there is no subsequent contracture and the texture is supple. Bone or cartilage graft can be incorporated within it. It can be shaped to restore the defect in nose, skin, ear, etc. Where the defect can be covered by mobilization of neighbouring skin, pedicle flap also gives very good result, as is so often done in facial defects.

WOUNDS AND DEFORMITIES

Accidental avulsion of skin and subcutaneous tissue is quite common in street and industrial accidents. The earlier the area is grafted consistent with safety, the better is the prognosis (figures 1 and 2, see plate XXIV).

In many recent wounds, specially in the face, every attempt should be made after primary excision to appose the wound margin as far as possible without tension. At the same time no deliberate plastic flaps and repair should be attempted at this stage. Mucosa should never be removed when the wound is kept open. In such cases the mucosa should be sutured with the skin margin. This often results in very little deformity, the final repair becomes easier and success more assured (figures 3 and 4, see plate XXIV).

CANCERUM ORIS

This forms the next common group of cases causing extensive destruction of facial tissues with ugly deformities. The gangrene is usually seen in the later part of enteric fever and also in kala-azar.

In the early stages actual destruction may be minimized with energetic oral hygiene, removal

of dead tissues and adequate drainage together with combating the infection.

Cases with deformities require careful planning and repair (figures 5, 6, 7 and 8, see plate XXIV).

As so often there is associated loss of bony support, one has to consider the repair of such defect with osseous or cartilaginous graft or dental prosthesis depending on which will give the better functional result (figures 9, 10, 11, 12, 13 and 14, see plate XXIV).

MALIGNANT GROWTH

Removal of a superficial carcinomatous ulcer or chronic ulcer (varicose) may leave behind large denuded areas. The covering of such an area by a graft may save the patient from an unnecessary amputation. One of the nurses of a hospital was admitted with huge ulcer 6 inches \times 10 inches on the back, lower half of which was adherent to the dorsum ileum. This was the result of intensive 'Chaul' therapy for an epithelioma developed on an unstable scar following burn. She was having agonizing pain in the scar and a continuous discharge from it. After complete excision of the ulcer including a shaving of bone and several attempts at mobilizing the flaps, ultimately in two months' time, the whole area became completely covered with flaps. But in the meanwhile she developed metastasis in the abdominal lymph glands and liver and rapidly became anæmic and died. Four days before her death she complimented me on curing what she had come to me for.

HARE-LIP AND CLEFT PALATE

By themselves, they form a very large group of cases for plastic surgeons.

Although the repair of hare-lip can be undertaken a few days after birth, generally it is not done till the second or third month of infancy when the child is sufficiently acclimatized to independent existence and the tissues are easier to handle.

In repairing hare-lip, the depth of the lip, symmetry of the alæ and vermillion border should be carefully restored to evenness. In doing this it is better not to spend unnecessary time at the first occasion since secondary correction is often needed, which personally I prefer to leave deliberately for another occasion (figures 15 and 16, see plate XXIV).

In double hare-lip with projected pre-maxilla, resetting should always be done some weeks before the repair of the lip. On no account should the pre-maxilla be excised (figures 17, 18, 19, 20, 21, 22 and 23, see plate XXIV).

The best time to operate with safety on cleft palate is between two and two-half years of age. There is, however, no age-limit for the repair of hare-lip, but when the operation for cleft palate is undertaken amongst the higher age groups the cleft can often be closed. In such cases phonetic

defect persists so that grown-up patients should be forewarned about this defect.

There are many other instances where either for kinetic reason or for cosmetic only, plastic repair is indicated. Deformity of nose, ear, eye, ptosis or hypertrophied breast, all require a specialist's knowledge and skill and should only be undertaken where success can be assured.

No attempt has been made here to describe the various operations or their pros and cons. It is rather with a view to increasing the interest in this branch of surgery that this has been written.

Descriptions of Illustrations

Figure 1. There is total loss of skin, platysma from below the chin to the chest, child cannot close the mouth and there is continuous dribbling of saliva. Near the right elbow, part of the pedicle prepared can be seen.

Figure 2. After spreading the pedicle in the neck. The chin is completely free, mouth is closed normally. The upper part of the chest is partly covered with Thiersch graft, as the scar over the area is unstable and breakdown.

Figure 3. Street accident. The volar and medial aspect of lower third of arm and upper two-thirds of forearm completely denuded of skin, subcutaneous tissue and deep fasciae muscles exposed. The area shown has been covered by a tube graft. The margins have been touched off by the photographer.

Figure 4. Severe kookri cut over the face, completely severing the nose, part of the orbital rim, and the two lids. A primary suture of the nose, both mucosal and cartilaginous parts, skin in tiers of suture. Primary union occurred with quite satisfactory result. The sutural line can be seen in the picture.

Figure 5. Destruction of whole thickness of cheek, the scar adherent to zygoma with salivary fistula, following enteric fever.

Figure 6. After repair mucosa mobilized and sutured together; skin and muscle flap raised from outer and lower aspect and mobilized to cover the mucosal flaps.

Figure 7. Same case showing defect over the mandible with salivary fistula.

Figure 8. After repair. While convalescing, he developed smallpox, marks of which can be seen on arm and leg but none the worse for it.

Figure 9. Post-typhoid cancerum oris with loss of two-thirds of upper lip, part of the cheek and angle of the mouth, also columella and floor of the left nostril.

Figure 10. After repair. A descending flap in the right side and an ascending flap on the left side, the lip is constructed, vermillion border was borrowed from oral mucosa of lower lip.

The patient had enteric like relapses twice and the wound broke away though partly, i.e. microstomia on the left side and absence of gingolabial sulcus.

Figure 11. Cancrum oris with loss of cheek and angle of mouth.

Figure 12. Angle of the mouth repaired and cheek gap filled up by mobilized flap of ascending type.

Figure 13. Cancrum oris in kala-azar, whole of the chin and lower lip, and ramus of both mandible from premolar to premolar lost.

Figure 14. A double-lined flap with pedicle raised from the upper part of the chest swung over to form the chin and lip. Remnants of vermillion border at the either angle of the mouth mobilized and sewn over the chin flap. Later a cartilage graft inserted to reconstruct the osseous support to the chin; angulation in the lower lip, junction of two mobilized part further improved.

Figure 15. Hare-lip.

Figure 16. After repair. Symmetry of nose and depth of the lip obtained.

Figure 17. Bilateral hare-up and pre-maxilla, completely free and projecting as a snout.

Figure 18. Lateral view.

Figure 19. After repair. Preliminary setting of the pre-maxilla. In later stage repair of the lip being done.

Figures 20 and 21. Syphilitic perforation palate (congenital).

After repair. These cases are difficult to mend due to extensive scarring that accompanies the lesion.

Functional result (phonetic) is poor due to contracted and rigid soft palate, velo-pharyngeal closure is imperfect.

Figures 22 and 23. Hare-lip in a young man. This young man submitted himself for operation after rejection by a girl. On the fourth day of operation after removal of stitches he suddenly left the ward.

Couple of days after he presented me with his final picture and informed me with a grin that the marriage had taken place.

PLASTIC REPAIR OF CONTRACTURES AND LATE TREATMENT OF BURN-SCARS

A REPORT OF 12 CASES

By MURARIMOHAN MUKHERJI

Resident Surgeon, Campbell Hospital, Calcutta

RECENT improvements in treatment of burns will certainly lower the incidence of bad scars with contractures. Bad scars causing symptoms or loss of function of a part of the body are really very few. In 1947, 91 cases of major burns were treated in the Campbell Hospital but only two cases developed contractures, one in the axilla and one in the fingers and both left the hospital before treatment was complete. All the

same contractures will form in some cases due either to wrong treatment or to want of facilities for proper treatment.

Twelve cases were treated by me in the Campbell Hospital in 1946, all of whom were healthy except for the contractures. Grouped regionally there were 4 cases of contractures of the axilla (holding the arm to chest wall), three of the fingers (in flexion and in extension), three of the elbow, and two of the ankle.

Qualities of scar

1. All these cases had fairly old scars, caused by burns, ranging from 2 to 24 years.

2. All the scars were mobile excepting two which were fixed to the superficial muscles, but none to the bone.

3. Ten cases had soft scars and two cases had very hard scars with tendency to form keloids; one was in the axilla and one was in the ankle.

4. No scar was unstable, i.e. with formations of ulcers now and then.

Palliative treatment of contractures

Scars usually take 6 months to mature. The character of the scar and consequently the ultimate deformity can be modified by proper palliative treatment. Massage, physical therapy, careful deep x-ray therapy, and irradiation will make the scars mobile and soft.

Active exercise to stretch the scars will not only elongate and mobilize the scar but will also stretch the normal skin beyond it, helping in apposition of skin after excision of the scar. The boy shown in figure 8 (see plate XXV) had a scar holding the arm to the side of the chest. He was asked to try to abduct his arm as much as he could and to increase the range. He did the same 30 to 40 times a day. Though the range of abduction was not increased materially, yet the skin of the chest wall and back was sufficiently stretched and mobilized. And it was certainly easier to cover the raw area after the excision of the scar with 'Z' plastic sutures.

Active exercise of muscles and tendons may also prevent scars getting fixed to them, provided the damage to the muscles and tendons is not severe. This simple procedure is very helpful specially in cases of injuries of fingers.

Preliminary deep x-ray therapy or irradiation is advocated for all cases having a tendency to form keloids.

Anæsthesia

General anæsthesia with open ether or gas, oxygen and ether was used for all cases. Some surgeons advocate local anæsthesia for all plastic operations but I find it inconvenient. My arguments are as follows:—

1. Uncertainty in the final procedure of treating the contracture, a scar after removal may give rise to an unexpected gap and one may have to choose some other method besides the pre-meditated procedure to cover the gap, e.g. a flap

graft designed to cover the defect being insufficient, one may have to take some razor grafts.

2. In almost all cases, the patient has to be tackled in more than one part of the body.

3. The infiltration of local anæsthetic distends the tissues and this may cause loss of proper alignment.

4. The stretching of the surrounding skin for closing a gap, however much undermining might have been done, may cause some pain when local anæsthetics are used.

5. Last but not the least important is the greater chance of infection of the wounds with the local anæsthetics.

Preliminary preparations

All examinations and preparations necessary for an operation under general anæsthesia were done. Donor sites for skin grafting were examined carefully and were noted down. The affected area was cleaned, painted with triple dye and covered with sterile dressings 48 hours before the operation. The donor sites for skin were cleaned and kept covered with sterile dressings. As a rule one or both thighs or some other suitable donor sites for razor grafts were always kept ready besides the areas meant for pedicle or flap grafts.

Operation theatre staff were always instructed to keep ready things like Stent's dental composition, measuring scales and callipers, sponges, etc., razors and equipments for Thiersch's graft, sticking plaster, plaster of paris, aluminium plates, etc., for fixation of parts.

Some general principles of operation and after-treatment

1. All scar tissues were excised though sometimes soft mobile scars were utilized for covering less important areas.

2. Portions of skin having incessant movements over deeper structures, i.e. skin over the joints, tendons, neck, hand, etc., were best repaired with full thickness skin with some amount of subcutaneous fat, i.e. pedicle or flap grafts or 'Z' plastic suture. If the whole area could not be covered in this way, the next best procedure, that was found almost as effective, was to place one or more whole thickness skin grafts transversely to the main line of the scar, i.e. transversely to the main line of tension of the skin over the joints.

Example.—A boy was admitted with a very extensive scar on the neck bending the face and the chin. On the same side the chest wall was also scarred. A transverse bridged flap from left pectoral region was placed across the excised scar. The rest of the raw area was covered by Ollier Thiersch's grafts (figure 1, plate XXV).

3. The donor sites were selected according to the necessity, condition of the skin and convenience of the parts. The flaps were dissected and sutured in proper place very carefully so that there was no inversion of the skin edges and there was full contact of the inner surface of the flap with the base of the wound.

4. The lines of suture and the flaps had no tension. The amount of tension that might be overlooked in repair of ordinary wounds was carefully avoided in these plastic repairs, as destruction of even a part of a flap might spoil the whole operation.

Example.—A boy had the forequarter of the foot raw all round. The part was placed under a double pedicle bridged flap on the inner aspect of the thigh. There was a little tension and the result was destruction of the middle of the flap as shown by the white scar on the corium of the left foot (figure 2, plate XXV).

5. Proper fixation of the parts and the grafts for the required period. The Thiersch's grafts were best fixed with rubber sponge and sticking plaster for 8 to 10 days. The pedicle grafts or flap grafts were fixed with plaster of paris bandages for 3 weeks. These were not disturbed before the scheduled time unless there was any question of sepsis or impaired circulation.

6. The flap grafts were shaped along the lines of their main blood supply and were sized according to the accepted principles (length : breadth : : 1 : 1 except in some sites as face and neck). Narrow long grafts were first delayed for 3 weeks.

7. The Thiersch's grafts were always of medium thickness. The big sized ones were always snipped at some points after they were spread over the raw areas. This simple technique prevented lifting up of the flap by exudates underneath.

8. Sepsis was controlled by administration of sulfathiazole both locally and systemically. As a rule a short course of 3 days of sulfathiazole administration was carried out with very encouraging results. None of my cases were spoilt by infection.

9. *Sites of scars.*—The most difficult of my series were the four cases of contracture of axilla. These four cases were treated by four different methods.

No. I.—Md. Abdul Gani, Mohammedan male, 35 years, history of burns 17 years back. There was no trace of the axillary cleft and the upper part of the arm was incorporated in the chest wall as it were. Rotation movements of the axilla were present proving that the joint was free (figure 3, plate XXV).

Treatment.—The arm was separated by making incisions on the skin of chest wall and back in such a way that the soft scarred skin could cover the raw surface on the medial aspect of the arm. The pit of the axilla was covered by inlay skin grafting on a mould of Stent's dental composition with much difficulty. The rest of the area was covered with Thiersch's graft as usual. The end result was not perfect (figure 4, plate XXV). The patient raised the arm to about the horizontal level but with much difficulty. The axillary space was getting scarred under thin Thiersch's graft.

No. II.—Brindaban Santra, Hindu male, 45 years, history of burns 3 years back. A fold of

soft scar was holding the arm to the side of the chest wall like a web. Movement of shoulder present but limited except rotation which was normal.

Treatment.—He was treated by 3 test tube grafts or tunnel grafts with medium thickness skin. The photograph shows the grooved bases of those tunnels (figure 5, plate XXV).

No. III.—Marjina Khatoon, Mohammedan female, 10 years, history of burns 4 years back. The scar tissue was soft and mobile, holding three-quarters of the arm to the chest wall (figure 6, plate XXV).

Treatment.—Preliminary exercise of abducting the arm helped in stretching the normal skin. Arm was separated by an incision which ran through the centre of the fold. The raw surface of the arm was covered by the soft scar. The pit of the axilla was covered by suturing the anterior and posterior axillary folds which were advanced by V-Y advancement flaps. The remaining raw surface was covered by Thiersch's graft. Arm was fixed in abduction at right angles for a fortnight and then she was asked to abduct it forcibly to stretch the muscles. The result was very gratifying (figure 7, plate XXV) but the line suture being along the axillary borders may develop some recurrence of scar.

No. IV.—Taijas Ali, Mohammedan male, 10 years, history of burns 6 years back. A fold of scarred skin was holding almost whole of the arm to the side of the chest wall. The scar was soft and mobile (figure 8, plate XXV).

Treatment.—Preliminary treatment of stretching the skin was very helpful. Arm was separated by an incision placed near the chest wall and the raw surface of the arm was covered by the scarred skin. The pit of the axilla was repaired by 'Z' plastic flaps (figure 9, plate XXV). The remaining raw surface was covered by razor grafts.

Post-operative treatment.—Active exercise to stretch the muscles helped in full abduction. The suture line being transverse to the axillary fold and old scar never hampered in the movements of axilla.

10. *Contracture of elbow.*—These 3 cases were treated by *test tube grafts*.

Santi Devi, Hindu female, 16 years, history of burns 6 years back. The right elbow was held in flexion by a scar tissue. The scar tissue was soft and had some healthy skin fold near the joint surface.

Treatment.—Medium thickness razor grafts were wrapped round 3 short thick test tubes with raw surface outwards. The grafts were fixed to the test tube by stout silk thread. Three small separate incisions were made through the healthy skin beneath the scar and through and through tunnels were created deep to the scar. Then 3 test tubes with grafts on them were introduced through the tunnels. The tubes were kept in position by tying the silk

threads over the scar covered with some dressings (figure 10, plate XXV). The elbow was fixed in plaster of paris cast for 10 days after which the tunnels made by the skin grafts were opened. The elbow could be fully extended as soon as these tunnels were opened (figure 11, plate XXV).

11. *Contracture of fingers.*—Two cases had contractures in flexion. They were treated by excision of scar, extension of the fingers with Brockman's pins and wire frames and application of medium thickness skin grafts kept in place by a mould of Stent's dental composition. The dressings were removed in 10 days' time but the extensions were kept for a fortnight. The results were fairly good, though after a few months the fingers became slightly stiff.

The third case had contracture in extension. This was a Hindu male, aged 26 years, with history of burns of right hand 17 years ago (figure 12, plate XXV). The skin of the dorsum of the hand was fashioned in such a way that the raw surfaces of the fingers could be covered by it. Then the raw area on the dorsum of the hand was placed under a bridged flap on the abdominal wall for 3 weeks. The connections were incised after this period and the wounds were closed. Considering the nature of contracture and its age (17 years old) the result seemed fairly good and it was certainly better than razor grafts on these tendons on the dorsum of the hand (figure 13, plate XXV).

12. *Contractures of ankle.*—One case had a thin mobile scar on the front of the ankle. The patient was a Hindu male, age 10 years, with a history of burns two years ago. The foot was held up in dorsiflexion. He was treated by test tube graft (figure 14, plate XXV).

The other case had a hard and slightly fixed scar. This was a Hindu female, aged 8 years, with a history of burns two years ago (figure 15, plate XXV). Treatment was by excision of the scar and by pedicle grafting in two transverse areas, one across the front of the ankle and one across the base of the big toe (figure 16, plate XXV). The rest of the area was covered with Thiersch's graft. The flap was taken from the back of the other leg. The result was fairly good (figure 17, plate XXV) though new formation of hard tissue might develop into a keloid. As a precautionary measure a course of deep x-ray was given.

Summary

(a) Twelve cases of contracture after burns were treated by different plastic operations with fairly good results.

(b) Pedicle grafts, 'Z' plastic sutures and 'V-Y' advancement flaps gave better results over the joints than the razor grafts.

(c) Preliminary treatment of scars helped in plastic repair.

(d) General anæsthetic was found to be more suitable than local in all cases.

(e) Incidence of infection was nil as sulfa-thiazole was used for a preventive course.

(f) Scars with a tendency to form keloids were better treated with whole thickness skin grafts.

I wish to convey my sincerest thanks to Dr. H. Rahman, additional teacher of Clinical Surgery, and his staff for the co-operation I always received from them. I am grateful to Major E. H. Lossing, Superintendent, Campbell Hospital, for allowing me to publish the records of these cases.

UNUSUAL TYPES OF FOREIGN BODIES IN THE GASTRO-INTESTINAL TRACT

By M. G. KINI, M.C., M.B., M.Ch. (Orth.), F.R.C.S.E., F.R.S.E., F.N.I., F.A.S.C.

Surgeon and Superintendent, Government Stanley Hospital, Madras

and
 I. CHALAPATHY NAIDU, M.B., B.S.

Civil Assistant Surgeon, Government Stanley Hospital, Madras

FOREIGN BODIES of various types in the gastro-intestinal tract have been reported. Textbooks on surgery commonly mention hair balls in stomach as a common example of foreign bodies among hysterical women. Clayton-Mitchell (1945) reported such a case in an African woman. Accidents among jugglers failing to get out what they had swallowed also are reported in literature. One such case was reported by de Soldenhoff (1937). Accidental swallowing of coins and lead pieces have been reported by Kini (1946). The psychological factors leading to swallowing of foreign bodies among soldiers have been discussed by Neustatter (1947) and Hallett (1947).

In recent times due to food shortage eating of dried fruits as substitutes has led to the causation of intestinal obstruction. Elliot (1932) reviewed 36 cases of foreign bodies causing obstruction during the previous 22 years. Jones and Davis (1945), Lyall (1945), Radclyffe (1945) and Ryan and Nagle (1945) have reported cases of ingested dried fruits causing intestinal obstruction.

Two cases are now reported of which one is interesting because a hysterical girl thought that she could commit suicide by swallowing broken bits of valet razor blades and glass bangles. The other case was an accidental swallowing of a broken bit of sewing needle and shows its progress in the gastro-intestinal tract without much damage to it.

Case 1.—A young hysterical girl, aged 20 years, while being examined for her general ailment in April 1946 asked by way of information whether swallowing of razor blades and broken bits of glass bangles would cause death. When questioned as to why she wanted this information she jokingly said that she had swallowed razor blades and broken bits of glass bangles. This information was not discredited knowing the mental make-up of the girl. A careful examination was made for any injury that might occur to the pharynx, gullet and gastro-intestinal tract. No sign of injury was detected on clinical examination and there was no evidence of colic, pain or tenderness in the abdomen. The possibility of her having swallowed the objects was still kept in mind and she was kept under strict observation with directions to the nurse to send information at once if any colic or pain was complained of.

The patient refused to take any food but drank copious draughts of water and she was given 4 oz. of Kaylenol at about 6 p.m., i.e. about 4 hours after the suspected swallowing of the blades. Eighteen hours afterwards an x-ray taken on mere suspicion, not on clinical evidence, showed broken bits of valet razor blades and broken bits of glass bangles in the large bowels. They had passed through the pylorus and the ileo-cæcal valve. In 48 hours all that she had swallowed passed out without any ill effects to the gastro-intestinal tract. It was difficult to imagine how she could have swallowed razor blades and broken sharp bits of glass bangles and also a pin without injuring her pharynx, œsophagus and the gastro-intestinal tract.

On careful enquiry the patient seems to have confessed later to her friend that she had swallowed the razor blades and bits of glass bangles by sandwiching them between slices of bread. It is interesting to observe that the glass bits and the razor blades passed through the gastro-intestinal canal without causing any injury to the mucous membrane or the walls especially while passing through the narrow channels in the pyloric and ileo-cæcal regions. There was no damage done to the anal orifice either when these bits with the sharp edges and ends were passed.

As she refused to take any food after swallowing the bits it is quite possible that she might have taken considerable quantity of bread while swallowing the foreign bodies. Ultimately these bits left the small intestine and got mixed up with the faecal matter already formed in the large intestine. The administration of Kaylenol helped in causing easy movement of the bits without any damage.

Case 2.—This case illustrates the course of an accidental swallowing of a broken bit of a sewing needle.

A Hindu girl, aged 15 years, was admitted for colic and bleeding per rectum with a history of having swallowed accidentally the broken bit of

a sewing needle which she had held between the teeth. This happened on 6th August, 1946, at 5 p.m. She ate some plantains, buns and rice at 7 p.m. On 7th August, 1946, at 7 a.m. she took castor oil about 1½ ounces. She had pain in the abdomen during defaecation and the same night passed bright red blood per rectum and developed colic. On 8th August, 1946, the third day of the accident, in the morning she again passed bright red blood per rectum for which she sought admission into the hospital at 10.30 a.m.

A plain x-ray was taken which showed the needle in the ascending colon with the sharp point directed upwards along the normal course of the current in the large bowel. In order to make certain that it remained in the bowel and not migrated into tissues and also to mix up and dislodge the needle with some heavy material, a barium enema was ordered at 2.30 p.m. At 3 p.m. after evacuation of the enema, x-ray showed no needle but it was not found in the evacuation. At 3.30 p.m. a rectal examination was made and the needle was found stuck horizontally in the rectum and was removed with the finger.

These two cases are reported for the following reasons:—

1. In the first case no ill consequence occurred after the swallowing of the razor blades and the broken bits of glass bangles for suicidal purposes. No operative interference was necessary to remove them and no discomfort or inconvenience was caused at the time of swallowing them, during their course in the gastro-intestinal tract, and during and after evacuation.

2. The second case was accidental swallowing of a needle which broke into two when held between the teeth. Unfortunately the sharp end of the broken needle was in the direction of the current of the gastro-intestinal tract and must have got stuck in the ascending colon to cause bright red bleeding. The barium meal enema helped to dislodge the needle and send it down the canal. Finally, it had to be removed by the finger from the lower part of the rectum.

List of illustrations (see plate XXVI)

1. X-ray picture taken 18 hours after swallowing of the razor blades and the glass bangles. The major portion of the blades have passed the ileo-caecal valve shadows of which are seen.

Note the longitudinal shadow in the region of the rectum which is a pin shown in picture 3.

2. Photograph of the broken bits of glass bangles swallowed mounted in a glass bottle.

3. Photograph of the pin swallowed.

4. and 5. Photographs of the broken bits of valet razor blades swallowed.

6. X-ray picture taken 2 days after the swallowing.

7. X-ray of case no. 2 showing the broken sewing needle in the ascending colon.

A STUDY OF WEIL-FELIX REACTION IN THE DIAGNOSIS OF TYPHUS FEVER IN BOMBAY*

By D. W. SOMAN

Haffkine Institute, Bombay

THE demonstration of causal rickettsia for early diagnosis of typhus fever is a time-consuming procedure and requires the use of a complicated technique as yolk-sac cultivation or inoculation of different laboratory animals. Serological tests such as the Weil-Felix reaction, complement fixation or rickettsial agglutination are much simpler to perform but the last two of these require specific rickettsial antigens; the preparation of these is not within the scope of an average small laboratory, so a laboratory worker has to continue to rely on the Weil-Felix reaction. Three serological varieties of *B. proteus* X, known as proteus X19, X2 and XK, are the only reagents by means of which the diagnosis of different varieties of typhus can be made.

As with many serological tests, the study of Weil-Felix reaction has brought to light certain anomalies and limitations that were not at first realized. Many workers have come to doubt its specificity on account of the reaction being positive during the course of other diseases. Factors such as standardization of technique, endemicity of infection, agglutinin level of local population, have to be reckoned with in the correct interpretation of this reaction. It is the purpose of this article to study the Weil-Felix reaction done on a large number of sera from pyrexial and apyrexial cases and to see how far some of

* This work has been carried out under the auspices of the Indian Research Fund Association.

the factors mentioned above interfere with the proper interpretation in the correct diagnosis of typhus fever.

Material and Method

To study the level of proteus OX agglutinins in the Bombay population, 500 sera sent for Wassermann test and 763 sera sent for Widal tests were tested for Weil-Felix reaction by the method described below. In testing sera for the Widal reaction, the combined method of clot culture and the Widal reaction (Soman, 1932, 1934) was used, so that 185 sera from bacteriologically proved typhoid and para-typhoid cases were available for study. Fresh alcoholic proteus suspensions were prepared from the three standard proteus strains every three months according to the method of Bridges (1944) and the Felix's (1944) technique was slightly modified. The tests were incubated at 50 to 52°C. instead of at 37°C. in the water-bath for four hours and kept overnight in the ice-chest for the final reading. Whenever a serum obtained from a pyrexial case showed a titre of 1:50 or 1:125 a repeat specimen was requested with a brief note on clinical history. Results of the Weil-Felix reaction on sera coming from pyrexial and apyrexial cases are summarized in tables I and II. Results of the same test on 185 samples of sera from typhoid and para-typhoid cases are summarized in table III, while the results obtained in 28 cases of clinically diagnosed typhus fever are shown in tables IV and V. Clinical history was available in 13 cases. In 9 cases of OX19 type, male guinea-pigs were inoculated intraperitoneally with 5 c.c. of patients' blood and in 3 cases of OXK type mice were similarly inoculated with 0.5 c.c. of blood.

It is known that sera from normal persons may contain low titre proteus OX agglutinins even in areas free from typhus infection. The results in table I showed only 3 sera out of 500 positive for proteus OX19 agglutinins in 1:100 dilution. Tables I and II, when considered together, showed that out of 1,263 sera examined, only 23 samples were positive in dilutions ranging from 1:50 to 1:125, giving a percentage

of 1.8; ten sera were positive in a dilution of 1:250 and 29 in a dilution of 1:500 or over. With the exclusion of those showing a titre of 1:250 or over, a very large number of sera was either negative or below a titre of 1:50. Weil (1920) in a series of 1,837 control sera from febrile and afebrile cases recorded only 1.2 per cent agglutinating the strain of proteus OX19 in 1:50 dilution; this titre according to Felix (1944) would have to be doubled to bring it on line with the results obtained by the use of alcoholic suspensions. A minimum diagnostic titre of 1:100 or 1:200 for typhus infection in non-endemic areas was suggested by many workers as MacKenzie (1941), McConn (1943) and Felix (1944). But Baker and others (1943), Brockbank and Whittaker (1944), Dyer (1944) and Dick (1946) did not feel justified in considering any titres below 1:480 as diagnostic of typhus infection. In the present series, as 98.2 per cent sera were found to be negative in a titre of 1:125, this titre could safely be taken as the minimum diagnostic titre for typhus infection in the presence of suggestive clinical history.

In order to study the problem of non-specific rise in Weil-Felix titres, 174 cases of typhoid and 11 of para-typhoid A infection were studied in relation to their Weil-Felix titres at different stages of disease.

Only one serum showed a titre of 1:250. This finding is of special interest in view of the confusing reference in the literature to the 'anamnesic rise in titre' due to non-specific infection and clearly showed that in the diagnosis of typhus infection, non-specific rise in titre due to enteric infection did not occur. Felix (1944), who investigated this possibility of non-specific rise in OX19 titres, observed for periods of several weeks typhoid, pneumonia and other febrile cases with and without history of previous typhus infection and concluded that even those patients who showed normal or residual agglutinins in titres ranging from 1:50 to 1:200 showed no re-stimulation of these agglutinins. The findings in the present series, therefore, appear to be in complete accord with those of Felix and are very significant because enteric fever figures so prominently in the differential diagnosis of typhus fever. A high residual OX19 titre may rarely lead to some difficulty in arriving at correct diagnosis necessitating repeat observations. Following is a case in point observed by the author:—

A sample of blood tested for Widal on the 17th day of illness showed typhoid O and H titres of 1:250 and Weil-Felix OX19 titre of 1:1,000. An enquiry into the clinical history of the case did not reveal any presence of rash or history of T.A.B. inoculation or previous typhus infection.

A repeat specimen later showed a rise in typhoid O and H titre of 1:500 with the Weil-Felix OX19 titre stationary. The clot culture was sterile twice. The subsequent rise in Widal titre, with the Weil-Felix titre unchanged, distinctly pointed to the true nature of infection which was subsequently confirmed by isolation of *B. typhosus* from the patients' stool.

The Weil-Felix titre in 28 cases of typhus infection was studied with many repeat observations. Serologically, 23 cases were of the OX19 type, 2 of OX2 type and 3 of OXK type.

The results of these cases fall into two groups. One group in which titres rose very high early above the diagnostic level (table IV) and the other in which they did not rise beyond 1:500 even during the third week of illness (table V). The possibility of such cases with low-titre reactions had to be kept in mind otherwise they were likely to be missed or wrongly interpreted. Frequent repeat observations to demonstrate rise in titre or the causal virus was the only method of arriving at correct diagnosis. Clinical history was available in 13 out of 28 cases. The infection was of a mild nature and showed many clinical features in common. The pyrexia was of a remittent or intermittent type lasting from 14 to 16 days, terminating by lysis within 2 to 3 days. Slow pulse, persistent headache and moderate leukocytosis were prominent features.

N.D.=Animal inoculation not done.

Rash was present in 4 out of 12 cases. Inoculation of patients' blood in male guinea-pig elicited febrile reaction in 6 cases out of 9. Only in 2 cases guinea-pigs showed pyrexia and typical Neill-Mooser reaction and *Rickettsia mooseri* were demonstrated in smears from the tunica exudate (table IV, no. 3 and table V, no. 2). Mice were inoculated intraperitoneally with blood from OXK type of cases and *R. orientalis* were successfully demonstrated in peritoneal exudate (table IV, no. 14 and table V, nos. 13 and 14).

In 8 out of 13 cases of typhus fever reported by Patel (1943a) and Patel (1943b) in Bombay, Weil-Felix titre did not rise higher than 1 : 500 even between 9th and 17th day of diseases. van den Ende and others (1943) in 12 cases of murine typhus in previously immunized persons with typhus vaccines observed that the disease assumed a mild form and the Weil-Felix titre did not rise higher than 1 : 500. Such observations and especially those reported from Bombay lend significant support to the author's findings in this article of 14 cases of typhus fever with low-titre reactions.

Conclusions

Typhus, as it occurs in Bombay, is chiefly flea-borne OX19 in type. Cases seen are predominantly mild, with or without rash, simulating other mild infections of enteric fever. The laboratory records of typhus cases in Bombay

do not represent the total incidence of this disease. Cases also occur in which OX19 titres may rise very high or remain low throughout the course of the disease. It is shown that the titre of 1 : 125 in the early stage of the disease can be taken as suggestive only when considered in relation to clinical history, while titres of 1 : 250 or higher as diagnostic of typhus infection. The low-titre reactions require, however, to be confirmed by repeat examinations to demonstrate rise in titre in all cases. Typhoid and para-typhoid infections do not influence Weil-Felix titres and do not give rise to anamnestic reactions and it is also true vice versa. Typhus cases of flea-borne variety may show both OX19 and OX2 titres but the OX2 titre is usually lower than OX19 titre. Ordinarily, OX19 titre does not differentiate epidemic or louse-borne infection from the endemic or flea-borne type, which can only be proved by doing complement-fixation tests. Typhus cases showing low Weil-Felix titres against *B. proteus* OX19 and high titre against *B. proteus* X2 or showing high OX2 titres only against *B. proteus* X2 (table IV, no. 13 and table V, no. 12) are probably cases of tick typhus reported by Megaw (1921) in India or cases allied to Rocky Mountain Spotted fever group of America, transmitted through ticks; the aetiology of this group remains yet to be worked out for India. Typhus cases OXK in type, which is a mite-borne infection, do occur in Bombay, but the number is proportionately

small. Significant titres against *B. proteus* OXK strains occur in relapsing fever (Robinson, 1942; Elsdon-Dew, 1943) which may cause errors in diagnosis. But no such cases have been observed in Bombay during the last twenty years. Typhus cases in which Weil-Felix reactions may remain completely negative throughout the course of the disease are reported in northern Australia and North America known as 'Q' fever. No such cases are reported in India so far. In India, correct data are not available as to the mode of transmission of rickettsial infection from one person to another, because the arthropod vectors and the reservoirs of infection have not yet been thoroughly determined. In spite of all these limitations and those discussed above, Weil-Felix reaction, though a non-specific agglutination test, appears quite diagnostic in at least three known varieties of typhus and should be carried out on every case of continued and irregular pyrexia, mild or severe, with or without rash, taking due care to exclude the diagnosis of enteric infection and certain other non-specific conditions discussed above.

Summary

1. Weil-Felix tests were carried out on 1,263 sera from pyrexial and apyrexial cases and a titre of 1 : 125 was shown to be presumptive of diagnosis of typhus infection in a pyrexial case with suggestive clinical history; a titre of 1 : 250 or over was considered as confirmatory of the disease.

2. 185 sera from proved cases of typhoid and para-typhoid infection were studied in relation to their Weil-Felix titres. The titres recorded were always below 1 : 250 except in one case in which Weil-Felix titre of 1 : 1,000 was observed.

3. The study of Weil-Felix titres in 28 cases of typhus fever showed that high- and low-titre reactions frequently occurred. In cases especially with low-titre reactions, repeated examinations for rise in titre were necessary to arrive at a correct diagnosis.

4. The problem of typhus, as it occurs in Bombay, is discussed with the rôle of Weil-Felix test in its diagnosis and its limitations stressed in the interpretation of results.

INSULIN SENSITIVITY AMONG INDIAN DIABETICS

By NITYA NAND GUPTA, M.D. (Luck.)
and

M. ABDUL HAMEED, M.D. (Luck.), M.R.C.P. (Lond.)
Department of Pathology, King George's Medical
College, Lucknow, India

(This work has been carried out under Kr. Inderjeet
Singh Endowment)

THE conception of the pathogenesis of diabetes mellitus has been greatly modified by the work of Himsworth and Kerr (1939) and later by that of De Wesselow and Griffiths (1938) in showing that a type of diabetes mellitus is due to the inhibition of the action of insulin within the tissues. This has led to the evolution of a new test, *viz*, dextrose-insulin test. Himsworth and Kerr investigated 36 cases of diabetes mellitus and have shown that under the standard conditions of diet and environments, diabetics react in two different ways :—

1. Insulin sensitive—when insulin comes into action rapidly and checks the hyperglycæmia or even causes depression of the blood sugar level.

2. Insulin insensitive—insulin comes into action only slowly and is unable to check the rising hyperglycæmia.

In their 36 cases, 24 proved to be insulin insensitive (= 67 per cent) while only 12 cases were of sensitive type. It was further shown by them that the effect of high carbohydrate diet was favourable to the insulin sensitive type of cases, as it rendered them more sensitive to insulin, while in the insensitive type it increased the glycosuria and also the fasting level of blood sugar with little or no increase in the patient's sensitivity to insulin. De Wesselow and Griffiths (1938) on the other hand showed the transformation of the insensitive to the sensitive type by a change in diet.

It was in the light of the above findings that an investigation on sensitivity to insulin was carried out on Indian diabetics with healthy non-diabetics serving as controls. A procedure somewhat different from that of Himsworth (1940) was adopted—

1. Venous blood (not capillary) was collected for the estimations of blood sugar; as by a simultaneous collection of capillary and venous

blood it has been proved by the above authors that the chief action of insulin lies in promoting the utilization of blood sugar in the peripheral tissues of the insulin sensitive cases, so that it is the venous blood which would better indicate the sensitivity of the tissues to insulin than the arterial (capillary).

2. Collection of specimens of blood was also done every $\frac{1}{2}$ hour for $2\frac{1}{2}$ hours and not for a shorter period of $1\frac{1}{2}$ hours as was done by Himsworth who collected the blood every ten minutes. This procedure was adopted by us in order to avoid any disparity in the timings of blood collection between the curves of dextrose-insulin test and that of the plain glucose-tolerance test. Moreover, it would further indicate the changes in the blood sugar for a longer period ($2\frac{1}{2}$ hours). In the beginning of this investigation blood was collected in a few cases every 15 minutes for the first hour but that did not seem to modify the curve and hence was given up.

3. In our series, glucose-tolerance tests were done by giving glucose at the rate of 30 gm. per square metre of the body surface and thus keeping a uniform standard of the amount of glucose in both the glucose-tolerance and dextrose-insulin tests. This was done for two reasons: (i) The two test curves may be uniform and comparable to each other and thus be able to demonstrate the action of insulin. (ii) It stands to reason that in a thin, emaciated and short statured person, the curve after giving 50 gm. of glucose cannot be compared to a curve after giving the same amount (50 gm.) of glucose to a tall obese person, because the amount of glucose utilized by the tissues should naturally depend on the body surface; hence for this test as well, the glucose given should be calculated according to the height and weight, as in the case of dextrose-insulin test. The amount of insulin was calculated at 5 units per square metre of the body surface determined from the height and weight formula of Du Bois as was done by Himsworth (1936). Lilly's make of insulin was used.

The diabetics were collected mostly from the wards of the College Hospital, where they were getting the full diet of the hospital, which contained a liberal amount of carbohydrates. A few who came from outside were also instructed to take a liberal carbohydrate diet as the carbohydrate deprivation leads to insulin insensitivity in both healthy and diabetic individuals.

The healthy controls were taken from the ophthalmic wards of the hospital, where they were admitted for some minor eye troubles and were getting the same full diet.

The typical curves from our series are shown in the following figures while the curves drawn by Himsworth and Kerr (1939) are shown in figure 5.

Comparing the curves of the two series, they seem to behave in a similar manner for the first hour so that the reading of sensitivity to

insulin in both the sets of curves during the one-hour period gives the same results. It is the further course of the curves which elicits the differential points of the two series.

I. Cases of diabetes mellitus

Thirty-six cases were investigated, ranging from mild cases to severe ones, varying in age from 21 years to 68 years. From the study of the insulin-dextrose curves of these patients it was clear that different grades of sensitivity were present ranging from an extremely sensitive to an almost insensitive type. Broadly speaking in this series: (1) Twenty-four cases were of the insulin sensitive type. (2) Five cases were of the insulin insensitive type. (3) Seven cases

Curve 1.—Typical sensitive type, from a case of moderate diabetes.

Curve 2.—Typical sensitive type, from a case of severe diabetes.

Curve 3.—Typical sensitive type, from a case of severe diabetes.

showed features difficult to classify within either group and were called intermediate type.

The criterion for this classification was that in the sensitive type of curve the insulin either suppressed or checked any rise of blood sugar for 1 hour; while in the insensitive type it failed to restrain the rising blood sugar and the curve remained more or less similar to the plain glucose-tolerance curve (e.g. curve 3). Others which did not fall into these two categories were named intermediate type; they showed:—

(a) Delayed action of insulin, i.e. there was an initial rise of blood sugar like that in the ordinary glucose curve but this was followed by a marked fall after $1\frac{1}{2}$ hours. This fall probably was simultaneous with the secretion of patient's own insulin. In one case of our series under this type, the blood sugar came down to a hypoglycæmic level (curve 7).

(b) An initial depression of blood sugar, i.e. in the first $\frac{1}{2}$ hour specimen after giving insulin and glucose. But very soon the blood sugar

started rising very high as if the insulin had been thrown out of action altogether. (e.g. curve 8).

Curve 4.—From a case of severe diabetes showing extreme sensitivity to insulin.

Curve 5.—Normal curve.

Curve 6.—Dextrose-insulin curves drawn by Himsworth.

(a) Insensitive type. (b) Sensitive type.

(c) Normal curve.

II. Control cases (normal healthy adults)

Twenty-four normal healthy individuals were tested including 10 persons above 45 years of age. In these non-diabetics the sensitivity to insulin showed variation from person to person. In some the fasting blood sugar was depressed to hypoglycæmic level in $\frac{1}{2}$ to 1 hour, though without any symptoms it quickly returned to normal. In others only slight depression of

Curve 7.—From a case of intermediate type showing delayed action of insulin.

Curve 8.—From a case of intermediate type showing initial depression followed by high rise of blood sugar.

10 to 20 mg. per cent of blood sugar was produced, followed by its return to normal or a little higher; still others had a comparatively irregular course. These normal curves essentially resembled sensitive diabetic curves.

In two out of this series of 24, the insulin response was poor, i.e. the blood sugar kept on rising after the administration of insulin and glucose for the first hour and the curve resembled the plain glucose-tolerance curve though less in its height (e.g. curve 9). This suggested that in certain individuals above 45 years of age ($= 1/5$ th of the total number in this series) there was less insulin sensitivity than others, so that they might be called 'potential diabetics' of the insulin insensitive variety. These cases, in spite of showing insensitivity to insulin, still possessed that amount of insulin response which prevented them from becoming diabetics.

Curve 9.—From a control case showing poor insulin response.

Review

It has been seen from the above that both in health and diabetes, insulin sensitivity varied from person to person on a more or less same diet and even with liberal amounts of carbohydrates. The two conditions, viz, insulin sensitivity and insensitivity, should not be regarded as two rigid and inelastic types as certain cases in our series showed intermediate or irregular type of response to insulin.

Thus both in the healthy and in the diabetics one may find different grades of sensitivity to insulin.

A. *Sensitive*. 1. Those markedly sensitive to insulin who react by marked suppression of their blood sugar (even amounting to hypoglycæmia in some healthy individuals).

2. Those showing sensitivity in a moderate degree reacting with an initial suppression of the fasting level of blood sugar which is soon restored to the normal and is maintained on it or slightly above (compare curves 1, 2 and 4).

B. *Insensitive or insulin resistant*. This includes those normal individuals of advanced age who are potential diabetics, i.e. who still retain that minimal amount of sensitivity to insulin which checks them from becoming

glycosurians. In others the insensitivity is pronounced enough to declare them diabetics.

C. Intermediate type. These have been described above. In healthy controls too, different grades of sensitivity were found between the two extremes of sensitive and insensitive types.

In the present series of 36 diabetics, the relative frequency of the sensitive and insensitive types showed figures reverse to those reported by Himsworth and Kerr.

5 were of insensitive type .. 14 per cent.

24 were of sensitive type .. 67 per cent.

7 were of intermediate type 19 per cent.

We are thus inclined to think that among the Indian diabetics the insensitive type is the least frequent.

Out of the healthy controls, only 2 (out of 24) were placed in group B, i.e. potential diabetics. From this series it seems that the potential diabetics among Indians are only 12 to 13 per cent.

Clinical features

It has so far been emphasized in the literature as pioneered by Himsworth and Kerr that there are clinical differences too, between these two types of diabetics, viz, the insulin sensitive type of cases are younger in age and thin built, their blood pressure is normal and their arteries are healthy and that their onset is sudden, severe and with marked symptoms. The insulin insensitive type is said to be obese, older and plethoric with hypertension and arteriosclerosis, having an insidious symptomless onset with only an accidental discovery of glycosuria. The cases recorded and investigated here absolutely differ from the classical description given above. In our series not one out of the five of the insensitive type was obese or plethoric or even symptomless. All the five complained of loss of weight along with thirst and polyuria. There were a few amongst the sensitive type in whom the onset of the disease remained unnoticed by the patient; glycosuria having been discovered in them, only when a few years later, they had some surgical complication. The most obese and plethoric patient of our series was a man of 42 years of age with 342 lb. weight for a height of 67 inches, and a blood pressure of 115/80 with a history of diabetes for the last 10 years but had no symptoms at all. Sugar had been discovered in his urine 10 years back when he got a carbuncle. His marked sensitivity is shown in curve 2.

Out of the 36 diabetics investigated, 16 were above 45 years of age of which 2 were of insulin insensitive type. The other three insulin insensitive type of cases were young men of 30 to 35 years of age, emaciated and thin with symptoms of polyuria and thirst. Thus the distribution of the insulin sensitive and insensitive types is irrespective of age. We are thus

inclined to say that amongst Indians the classical description of the two types of diabetics as given by Himsworth does not at all hold true.

Summary

1. Some modifications of both the dextrose-insulin test as well as of the glucose-tolerance test are suggested to enable making an uniform comparison of the two types of curves in the same person as well as in different individuals. The modified technique of dextrose-insulin test not only avoids too frequent pricks for the patient but also gives a better idea of insulin sensitivity as venous blood would indicate insulin sensitivity better for the reasons described above, while the longer duration of curve affords a better study of the range of insulin reaction in the patient.

2. The relative proportion of insulin sensitive and insulin insensitive types of Indian diabetics is found to be 67 per cent and 14 per cent respectively.

3. Sensitivity to insulin is shown to have every gradation from person to person in health and in diabetes. An intermediate type between the sensitive and insensitive types of diabetics has been described.

4. Classical description of the clinical features of the two types of diabetes (sensitive and insensitive) has not been confirmed and does not hold good for Indian diabetics.

PHTHALYLSULPHATHIAZOLE IN THE TREATMENT OF CHOLERA

By C. L. PASRICHA

LIEUTENANT-COLONEL, I.M.S.

Director, School of Tropical Medicine

B. M. PAUL

A. C. DAS GUPTA

and

A. K. DAS

(From the Cholera Treatment Unit, Indian Research Fund Association, School of Tropical Medicine, Calcutta)

PHTHALYLSULPHATHIAZOLE has been reported to be an effective remedy in the treatment of dysentery, diarrhoea and other intestinal fluxes. Streicher (1945) considers this drug to be less toxic and more effective than any other intestinal antiseptic previously used. It was considered

desirable to try this preparation* in the treatment of cholera. The patients, who were in-patients of a cholera hospital, were divided into two groups on admission. The first group was treated with phthalylsulphathiazole 3 grammes, 4-hourly during the acute stage of the disease and twice a day for two days afterwards. The second group served as control. All patients received the usual saline supportive treatment. All patients were suffering clinically from cholera. The clinical diagnosis was confirmed by the isolation of agglutinable vibrios in a number of cases, but it was not possible to make full bacteriological examination in each case.

The selection of cases for treatment was made on alternative admission basis. The only criterion used in the analysis of treatment has been recovery or death. Whether the patients died within few hours after admission or whether death occurred from other causes than cholera, has not been taken into account. All cases were taken as cholera and all deaths due to cholera.

Results of treatment of parallel series of cholera cases with phthalylsulphathiazole, and a control series not receiving any sulphonamide drug

	Treated with phthalylsulpha- thiazole	Control
Number in series	331	335
Number recovered	307	301
Number died ..	24 or 7.3%	34 or 10.1%

Although the death rate (7.3 per cent) is less in the phthalylsulphathiazole series than in the control series (10.1 per cent) the difference is not significant.

SULPHASUXIDINE IN THE TREATMENT OF CHOLERA

By C. L. PASRICHA

LIEUTENANT-COLONEL, I.M.S.

Director, School of Tropical Medicine

B. M. PAUL

A. C. DAS GUPTA

and

A. K. DAS

(From the Cholera Treatment Unit, Indian Research Fund Association, School of Tropical Medicine, Calcutta)

In the report of the Indian Research Fund Association of 1944 (page 2), it was reported that 118 clinically diagnosed cholera cases were

treated with sulphasuxidine and a similar number of alternately admitted cases used as controls. The usual saline supportive treatment was given to both series. Death rate in the sulphasuxidine treated and control series was 10 per cent. As far as we are aware, no further trials of sulphasuxidine in the treatment of cholera have been reported. During the recent cholera epidemics it was decided to try sulphasuxidine in a series of cases. The selection of cases for the treatment with sulphasuxidine was on alternate admission basis. The patients were suffering clinically from cholera. The clinical diagnosis was confirmed by the isolation of agglutinable vibrios in a number of cases, but it was not possible to make full bacteriological examination in each case. Sulphasuxidine was given in dosage of 3 grammes, 4-hourly during the acute stage of the disease and twice a day afterwards for two days. The results are presented in the table :—

	Treated with sulphasuxidine	Not treated with sulphasuxidine
Number treated	195	194
Number recovered	184	182
Number died ..	11 or 5.6%	12 or 6.2%

Sulphasuxidine in the dosage used had no effect in reducing the mortality in cholera. No untoward effects were noted in cholera cases after its use.

AN OUTBREAK OF PELLAGRA SYNDROME IN A RURAL AREA OF BENGAL

By R. N. CHAUDHURI, M.B. (Cal.), M.R.C.P. (Edin.), T.D.D. (Wales), F.S.M.F.

Professor of Tropical Medicine

and

H. CHAKRAVARTI, M.B. (Cal.)

Assistant Research Officer

(From the Department of Tropical Medicine, School of Tropical Medicine, Calcutta)

EARLY this year a local daily paper reported about an outbreak of a 'mystery disease' in Navadwip in the district of Nadia about 66 miles from Calcutta. The Chairman of the Municipality had also written to the Director of the School about it, emphasizing a state of panic amongst the villagers. As directed by the latter three patients were brought and admitted to the Carmichael Hospital for Tropical Diseases on 26th February, and we visited the affected locality on 4th March and again on 18th for investigation.

* The phthalylsulphathiazole used in this trial was kindly donated by Messrs. May and Baker Ltd. and Messrs. Herts Pharmaceuticals Ltd., England.

Information collected showed that the town of Navadwip itself was not affected although a few patients had gone there for treatment. The disease was mostly confined to a section of a village called Gholapara-Fakirdanga situated at a distance of five miles from it on the opposite bank of the Ganges. We were told that the disease was not quite new to the locality; it had occurred several times before, though not regularly since 1938, with a number of deaths. The present outbreak began at about the end of December 1946, and lasted till about the end of March 1947.

This village consists of three parts—the northern, central and southern—occupied by Hindus, Moslems and Hindus respectively, the disease being confined to the last section only. This area contains some 50 houses with a population of about 400 of which nine families were affected. The incidence of the disease in different families is given below :—

Family incidence

Serial number	Total members	Number affected	REMARKS
1	9	9	Including a pregnant woman who died three months later.
2	4	4	One died.
3	2	2	
4	7	3	
5	2	2	This family consisted of 7 members. All were affected last year when 5 died.
6	5	1	
7	4	1	
8	3	2	
9	4	2	

The patients.—The subjects of this analysis were 22 patients including three that were admitted to the hospital and another patient brought to us during our second visit from an adjoining village in which one whole family of 5 members was affected (not included in the above table).

They are mostly cultivators by occupation and own some lands; the men work in the fields, the women engage themselves in domestic duties. They live on the sale of field products, keeping what is just necessary for their own consumption. A number of them belong to the poor labouring class, some being engaged as servants. In this series, family no. 1 had a servant who lived with his own family but took all meals at his master's house. He fell a victim to the disease but his own people were unaffected.

Rice is the staple food; they use their own rice parboiled and husked at home while poorer classes who do not possess any land usually buy it from Navadwip market where it is uncontrolled. It is supplemented by vegetables and dal. Some take a little milk, but fish, eggs, fruits

and meat are hardly ever taken. Usually they have three meals a day, all consisting of rice and vegetables, the early morning meal being the rice kept overnight in cold water. They throw away the rice-water after cooking. As a rule, they use the Ganges water for drinking purpose except during rains when it gets very muddy and they use well-water. The dietary did not differ in any way from that of the non-affected people.

We collected samples of rice from some affected and some unaffected families in this locality. A notable difference in the naked-eye appearance was obvious between the two groups of samples. Samples from affected families invariably contained many grains which were black, while those from unaffected families contained none. The former was also said to give a slightly bitter taste on chewing. We were told that owing to scarcity of water in certain fields (presumably on higher levels) many of the paddy grains were 'dead' and turned black during preparation. The affected families had paddy fields close to each other in one area.

Sex.—The series included 13 males and 9 females. It is evident therefore that both the sexes were almost equally affected.

Age.—Their age distribution is given below, the youngest being 5 and the oldest 55 years.

Under 15 years	6
15 to 25 years	8
Above 25 years	8
			—
			22

Clinical features.—From the history of the duration of the illness the patients can be divided as follows :—

Duration	Number of cases
Under 4 weeks 3
4 to 6 weeks 9
More than 6 weeks 10

There was history of similar attacks in both the members (mother and daughter) of the family no. 5 last year when five others had died of it. The mother had still evidence of peripheral neuritis presumably as a sequel to the last attack. The onset of illness was insidious.

Gastro-intestinal symptoms were complained of by 20 patients. The incidence of these symptoms which persisted in many of them is shown below :—

Anorexia 18
Nausea 16
Diarrhoea 7
Ptyalism 7
Gripping pains 7
Vomiting 2

Some form of dermatitis was a constant feature. It was actually present during our

examination in 19 cases, the lesions having cleared up in 3. It appeared first on the face in 8 cases, on the feet in 8 cases and on the hand in one case. The remaining patients were not sure of the initial site of lesions. The usual story was that after a few days of prodromal gastro-intestinal symptoms reddish brown patches appeared on the face, usually in the malar region and/or dorsum of the feet or hands. Those on the face appeared on both sides and looked like severe sun-burn or erythema which persisted as such for a variable period and then the patches became dark and rough followed by desquamation. In this series 16 patients had definite cutaneous changes on the face. Except one left with hypopigmented patches all of them had flushed or hyperpigmented areas, the face being definitely puffy in three. The patches on the extremities rapidly became dirty black and rough and were confined mostly to the dorsal aspect of hands and feet.

The lesions appeared to be typical pellagra dermatitis in 9 out of 19 cases. They were symmetrical, the affected skin being thickened, rough, black and sharply demarcated from healthy skin. The remaining ten patients that we saw had also pigmentary dermatosis of hands and feet but the lesions were of different and varied type unlike classical pellagra lesions. Some had no dermatitis on the dorsum of the feet but the outer borders of their feet became brown, and then darkened, keratinized and peeled. The dorsum of several toes or fingers (especially knuckles and inter-phalangeal joints) turned brown or deep black in some. Sudden or ulcerated condition of the clefts between toes were also seen in a number of them. Deep fissures or cracks developed in the soles and palms of some patients. A few had symmetrical dark patches on both malleoli or heels.

Other lesions in this series included cheilitis in 4, angular stomatitis in 5, glossitis in 7 and tremulous tongue in 8. One woman (family no. 5) who also had the disease last year showed evidence of peripheral neuritis.

Examination of other systems showed no obvious abnormality. General health was fair

in most cases. The blood pressure was within normal range. There was one death this year—a boy of family no. 2—the terminal symptom being vomiting of blood.

Some of the hæmatological findings are given in the table. The hæmoglobin in a series of 13 patients varied from 10.2 gm. per 100 c.c. (75 per cent) to 14.85 gm. (108 per cent). Excepting 3 all had hæmoglobin above 11.0 gm. (80 per cent). It was also estimated in 7 unaffected individuals of the locality. This varied from 11.8 per cent to 13.95 gm. Thus the hæmoglobin level of these patients was what is about the average in this class of people.

Plasma protein estimations done on a representative series of 13 patients showed that the mean plasma protein concentration was 6.2 gm. per 100 c.c. compared with 7 gm. per 100 c.c. for the control group, whereas the mean plasma albumin level was 3.3 gm. and globulin 2.9 gm. per 100 c.c. Thus there was some reduction in plasma protein which was entirely in the albumin fraction with globulin normal or slightly increased in some cases.

This is shown in the low 1.1/1 albumin/globulin ratio compared with a normal of 1.8/1.

Examination of urine and stools of 3 patients admitted to the hospital showed no abnormality. W.R. was negative and gastric analysis showed presence of free HCl. Nicotinic acid excretion was normal in two cases and defective in one.

Treatment.—In hospital, two patients (cases 8 and 19) were given full hospital diet and one patient (case 9) was kept on milk diet for a week. This alone was sufficient to cause some improvement. Thereafter the first two patients were given nicotinic acid 300 mg. daily for 12 days while the last one was put on full hospital diet but without nicotinic acid. This caused further improvement; the skin lesions practically cleared up, and they were discharged on 15th March, 1947.

In this village 6 patients had treatment given by a local doctor who advised better diet with

Serial number	Case number	Hæmoglobin		Total protein gm. per 100 c.c.	Albumin gm. %	Globulin gm. %	Albumin/Globulin ratio
		gm. %	Hellige %				
1	1	12.1	88	6.2	2.7	3.5	0.8
2	2	11.5	84	6.5	3.6	2.9	1.24
3	3	12.4	90	6.2	3.5	2.7	1.3
4	7	13.5	98	6.2	3.6	2.6	1.4
5	8	14.0	102	6.2	3.3	2.9	1.1
6	9	13.2	96	5.8	3.5	2.3	1.5
7	10	11.0	80	5.8	2.6	3.2	0.8
8	11	10.5	76	5.8	3.3	2.5	1.3
9	12	10.3	75	5.4	2.6	2.8	0.9
10	17	11.8	86	7.5	3.7	3.8	0.9
11	19	12.9	94	6.8	3.8	3.0	1.2
12	20	14.8	108	5.8	3.0	2.8	1.7
13	21	12.1	88	6.8	4.0	2.8	1.4

fish daily and gave them a course of about 12 or more injections of nicotinic acid; all improved. The remaining patients had little or no treatment and their condition was either stationary or progressive at the time of our visit. They were advised to

(a) change the rice,

(b) supplement the diet with germinating grams, peanuts (china badam), fish, milk and tomatoes,

(c) nicotinic acid by mouth.

After a fortnight, during our second visit, we found that all had changed the rice straightway, but only a few had any supplements and had just started (not more than 3 days) nicotinic acid. Some had also multivitamin tablets. All improved and there was no more fresh case (except case 22 who belonged to a different village and was not seen before).^{*} This seems to show that the common factor leading to improvement was the change of diet, presumably the rice.

Discussion

Clinically the condition appeared to be pellagra. Practically in all the cases the disease started with gastro-intestinal symptoms such as anorexia, nausea and diarrhoea. This was followed by a skin lesion which was typical in 9 out of 19 patients we had occasion to examine. Quite a number of them had tremulous tongue and some had other deficiencies as well, viz, cheilitis, angular stomatitis and glossitis. One woman who had previously suffered from it and also got an attack during the present outbreak showed evidence of peripheral neuritis. The diet of the community is grossly deficient and seems to be the cause of the syndrome. Judging from the symptoms there must be multiple deficiencies, mostly of vitamin B complex, concerned in its production. It is however not clear why a larger part of the community having the same diet remained apparently free. The only difference that we could notice was that the rice of those who had the disease had a large number of black grains imparting a bitter taste unlike the rice of the non-affected people. It was thought that these 'dead' grains might have been deprived of the bulk of their natural vitamin B complex including nicotinic acid. The nicotinic acid content of the samples of rice was however found to be within normal range. Another possibility is the presence of some toxic substance in those grains precipitating the deficiency state.

Our thanks are due to the Chairman, Navadwip Municipality, for assistance in this investigation, and to Dr. Rajagopal, All-India Institute of Hygiene and Public Health, Calcutta, for estimation of nicotinic acid in the rice samples.

XANTHOMA DIABETICORUM

(A CASE RECORD)

By J. P. BOSE, M.B., F.C.S. (Lond.)

and

L. M. GHOSH, M.B. (Cal.), D.T.M. (Liverpool)

(From the Department of Biochemistry and Diabetes, School of Tropical Medicine, Calcutta)

XANTHOMA DIABETICORUM is undoubtedly a rare complication of diabetes. A review of the literature on the subject by various workers in the field shows that during the last 100 years the number of cases described would not exceed a hundred and fifty. One of us (J. P. B.) during the last 25 years came across only two typical cases. This evidently has been the experience of most of the other workers in the field.

The first description of this disease was given by Addison and Gull (1850) who gave such an admirably clear description of the skin lesions in Xanthoma Diabeticorum, that it still remains unsurpassed. In describing the skin lesion of their diabetic patient, the authors wrote: 'An eruption somewhat suddenly appeared on the arms, at first apparently of a lichenous character. In the course of 10 days, it had extended over the arms, legs and trunk, both anteriorly and posteriorly, and also over the face and into the hair. It consisted of scattered tubercles of various sizes, some as large as a small pea, together with shining coloured papules. They were most numerous on the outside and back of the forearm and specially about the elbows and knees where they were confluent. Along the inner side of arms and thighs, they were more sparingly present, and entirely absent from the flexures of the larger joints. They were of a yellowish colour, mottled with deep rose tint, and with small capillary veins here and there ramifying over them. They were accompanied with a moderate degree of irritation, hence the apices of many were rubbed and inflamed.....'. Similar cases were described by many workers. Walker in 1897 reviewing the literature on the subject during the previous 50 years could collect only 30 cases. Major (1924) collecting cases of Xanthoma Diabeticorum from the literature during the previous 75 years could collect only 74 cases, he himself describing 4.

Coming to the more recent literature, Wise and Garb (1942) described a case of an unusual form of eruption of Xanthoma Diabeticorum in which the lesions were composed of keloid-like growths on the extensor surfaces and sides of the upper and lower extremities.

The skin condition as described by various authors since it was first described about 100 years ago by Addison and Gull in 1850, though differing in minor details, appears generally to conform to the following descriptions:—

1. That the eruptions were of a spotty distribution with predilection for extensor

^{*} No case was encountered during our third visit, several months later.

surfaces of the feet, arms, elbows and the extensor surfaces of the body.

2. The size varied usually from that of a pin head to a small pea.

3. The eruptions were usually symmetrical and discrete but confluent papules attaining various sizes have also been described.

4. The nodules were usually of a yellowish or brown colour with a red inflammatory areola round the nodules.

A careful study of the literature on Xanthoma Diabeticorum clearly indicates that certain differences of opinion exist as to the correctness of the diagnosis in some of these cases. Without going into controversial details of discussion it appears to us that although the criteria for diagnosis may be too severe, yet certain cases, described in the literature as Xanthoma Diabeticorum, probably have no claim to this title.

Description of the skin condition of the present case

Practically the whole body and the extremities were covered with small yellow coloured papular lesions. The extensor surfaces of the limbs suffered more than other parts. On the face, the lesions were small, discrete and confined mostly to the forehead. On the trunk, the back suffered more than the front and the lesions were small and discrete. The back of the elbows and front of the knees were the worst (figure 1, plate XXVI). On the hands, the lesions on the sides and back of the fingers and the webs between the fingers simulated scabies (figure 2, plate XXVI). The palms of the hands and soles of the feet were sparsely affected. The thighs, legs and dorsum of the feet had the same conditions like the upper limbs. The individual lesions were yellow or orange-coloured flat-topped papules varying in size from a pin head to that of a split pea. Most of these were solid but some were soft in consistency. Over the big joints and on the extensor surfaces of the limbs, some of the lesions coalesced to form fair-sized plaques. The red areola around the papules described in the textbooks were not marked. The lesions were irritable but not so severe as to cause any abrasions due to scratching.

Histopathology

The epidermis was mostly unaffected. The main changes were confined to the corium. In the sub-papillary layer, the capillaries were dilated in the affected area and there were cellular infiltrations round the dilated capillaries and also throughout the corium. These cells consisted of endothelial cells, round cells and epithelioid cells. There was all-round fatty fibrous degeneration in the corium, the fatty degeneration more marked than the fibrous changes which were just beginning. Throughout the whole corium were found deposits of fat globules and granules both inside the degenerated cells and in the intercellular spaces (figure 3, plate XXVI).

The fatty deposits consisting of fat globules and granules were due to fatty infiltration in the corium and fatty degeneration inside the cells. The cellular degenerations consisted of formations of large cells derived from connective tissue, the nuclei were small and deeply stained and the protoplasm full of fatty materials. Some of these cells contained more than one nuclei. The fibrous changes were slight and just beginning but the cellular changes were well marked giving the appearance of the lesions being inflammatory in character. The histological picture was that of xanthoma of inflammatory nature.

Observations upon the appearance of blood or upon the blood chemistry of patients with Xanthoma Diabeticorum have been few in number: all recent observers, however, agree that a condition of lipæmia and hypercholesteræmia occurs in almost all cases.

The question whether Xanthoma Diabeticorum is solely due to lipoidemia or is the result of some inflammatory reaction produced by a slight trauma has been the subject of a long debate. One such case has been described by Major in 1924. A young diabetic boy with a blood sugar of 322 mg. and a blood cholesterol of 400 mg. per 100 c.c. was bitten in two places on the forearm by a mosquito. Two small inflammatory nodules were produced and a few days later a deposit of yellowish orange pigment appeared, and the nodules became quite hard and presented a typical appearance of the lesions of Xanthoma Diabeticorum. We hold that trauma may be the *immediate* causative factor in these cases and agree with the author that lipæmia is an essential factor and a condition precedent without which Xanthoma Diabeticorum cannot occur.

Clinical features

The case described in this paper presented a few unusual features, the most noteworthy being that though the hyperglycæmia and the lipæmia were pronounced and though the skin lesions were widespread, the marked improvement in the clinical condition, the quick disappearance of the hyperglycæmia and the lipæmia and the resolution of the skin lesions were almost dramatic. On a review of the literature we find that a case of a similar nature was described twenty years ago by Goldstein and Harris (1927). It is also significant to note that a fat-free, high carbohydrate diet with insulin produced a fall of both blood sugar and blood cholesterol. The smaller nodules disappeared but the larger areas having a poor blood supply did not respond so easily.

Though there were clinically no signs of acidosis at the time, it was feared that on account of the faulty fat and carbohydrate metabolism this condition might develop if precautions were not taken immediately. Fat-free diet was therefore prescribed.

Such a serious state of affairs as noted above occurring particularly in a young boy naturally suggested a bad prognosis at the outset but the boy improved rapidly on treatment and left hospital in quite good health.

The nodules were usually symmetrical, about the size of a thick pin head or head of a match stick. They were slightly irritable and bled readily when scratched. Discomfort, however, began to lessen as the patient's condition improved.

The patient was a village schoolboy aged 20 years. No definite history of severe polyuria, thirst, emaciation and extreme weakness could be obtained for the last 6 months or so. According to the patient the 'eczematous' condition of the hand and feet with swelling was recent (about 3 weeks) and that was what made the parents anxious to put the boy in hospital.

On a preliminary clinical examination the first thing that struck us was that the boy was mentally sluggish. On enquiry it was revealed that the father also noticed this mental change in the boy which he attributed to severe ill health. The boy could understand questions put to him but his answers were incoherent and vague. The diabetic condition of the patient was severe. The patient had a polyuria reaching 5,760 c.c., a glycosuria of 8.0 per cent and a daily waste of 460 gm. of glucose. The fasting blood sugar level, 0.340 per cent, and a low carbohydrate tolerance as evidenced by the results of the glucose tolerance tests. Added to this was the xanthoma and the obvious deficiency in fat metabolism as evidenced by the very high lipid and the cholesterol content of the blood.

It would be interesting to note here that when the first sample of venous blood was collected it was found to have a curious opaque or cloudy appearance and a white 'cream' rapidly separated on the top of the fluid (lipæmia).

Other laboratory findings

The following are some of the other findings elicited during the routine examination of the patient:—

Stool.—

Negative for protozoa in 4 serial examinations.

Ova.—

Ascaris ++ } for which a thorough treatment
Trichuris ++ } was given.

Blood count.—

R.B.C. 555,000

W.B.C. 12,600

Polymorphs 72%

Lymphocytes 18%

Large monocytes 7%

Eosinophiles 3%

Blood chemistry.—

Blood sugar 0.340%

Urea N. 0.010%

N.P.N. 0.028%

Calcium 0.010%

Uric acid 0.0028%

Cholesterol 0.720%

Glucose tolerance test (oral method).—

Fasting blood sugar	0.340%
½ hour after 30 gm. of glucose ..	0.360%
1 hour after 30 gm. of glucose ..	0.390%
1½ hours after 30 gm. of glucose ..	0.340%
2 hours after 30 gm. of glucose ..	0.336%
Urine sugar before	7.5%
Urine sugar after	10%

Glucose tolerance test (I.V. method).—

(Dose—0.2 gm. per kilo.)

Fasting blood sugar	0.230%
15 minutes after glucose	0.320%
30 minutes after glucose	0.345%
45 minutes after glucose	0.285%
1 hour after glucose	0.260%
1½ hours after glucose	0.240%
Urine sugar before	4.5%
Urine sugar after	7%

Urine.—

Sugar	8%
Albumin	+
Acetone	+

The patient was put under intensive antidiabetic treatment (fat-free diabetic diet with insulin) and the result was extremely satisfactory. The blood sugar returned to the normal level and the urine became free from sugar and acetone within a short time. Along with the improvement in the diabetic condition the skin condition improved considerably until it finally disappeared. He was discharged apparently cured on 25th March, 1947.

Summary and conclusions

1. A rare case of typical Xanthoma Diabeticorum in a young boy of 20 years has been described.

2. The noteworthy features of the present case were the marked improvement in the clinical condition, the quick disappearance of hyperglycæmia and lipæmia and a resolution of the skin lesions though the hyperglycæmia and the lipæmia were pronounced and though the skin lesions were widespread.

3. It appears to us that Xanthoma Diabeticorum is related more closely to the fat metabolism of diabetes mellitus than to the carbohydrate metabolism.

UNUSUAL FATAL HÆMORRHAGE COMPLICATING ENTERIC FEVER

By M. K. CHHETRI, M.B. (Cal.)

Medical Registrar, Medical College Hospital
and

M. N. DE, M.B., M.R.C.P. (Lond.), F.S.M.F., F.N.I.
Professor of Medicine, Medical College Hospitals,
Calcutta

ENTERIC fever is remarkable for the large number of complications which may occur during its course. Most of them are very well known to the medical profession with their pathogenesis and prognostic significance. In this paper the writers intend to discuss a very serious complication which they have met with in the routine management of their enteric cases. The literature on the subject is extremely meagre and their clinical description is hardly found in any textbook. The pathogenesis of the condition is a matter of speculation but the prognostic import is very definitely bad. It is for these reasons that the subject is brought forward to elicit opinion and stimulate scientific interest.

Clinical features of these cases are as follows: A case of long-continued fever proved bacteriologically and serologically to be due to one of the enteric group of infections runs its entire course without any incident during the first 2 or 3 weeks. Towards the end of the course of the fever or in some cases even when the temperature has subsided and the patient is in the stage of convalescence and for all practical purposes considered fairly out of danger, he suddenly has a set-back due to an unusual complication, *viz*, vomiting. At first, the physician takes it to be due to some error in diet producing perhaps a mild gastritis. This complacency is, however, soon changed into a serious matter when the patient begins to show presence of blood in the vomited matter—either frank blood or altered blood or more usually coffee-ground material. The quantity may be moderate or large and the number of vomits may be as many as 10 to 12. There may be some mucus along with the blood. With this hæmatemesis, sooner or later, the patient begins to pass blood *per anum*—usually melæna of large or small quantity. In a few cases, the melæna may precede the hæmatemesis. The patient sooner or later develops some degree of jaundice, becomes rapidly anæmic, passes smaller and smaller quantities of urine and finally dies.

In a group of 10 cases studied, this complication appeared on an average between the 18th and the 24th day of the illness. In 2 cases, however, it started as early as the 10th day, whereas in another 2 cases, it appeared as late as the 32nd and 52nd days respectively. The temperature, just previous to the onset of the complication, showed interesting features. In 5 cases, it was normal for a variable period of 1 to 8 days before the hæmatemesis started. In

3 cases, the fever was coming down by lysis when vomiting began and the temperature maintained normal till death occurred. In one case, the temperature was subnormal. There was only one example where the complication started when the temperature remained high (103°F.). Signs and symptoms of intestinal hæmorrhage with passage of tarry stools occurred in 2 cases just previous to the onset of the hæmatemesis. Three cases had melæna after the hæmatemesis. In the remaining 5 cases, hæmorrhage from the stomach was not associated with visible hæmorrhage from any other part of the gastro-intestinal tract. Purpuric spots appeared on the hands and forearms in one case only. Except 2 cases, where the vomited material consisted of frank blood, there was altered blood in all the rest and the vomited matter looked like coffee-ground material. In 6 cases, jaundice developed, preceding or following the hæmatemesis by a day or two.

Widal reaction was positive in 5 cases. Blood culture was successful in 3 cases while in 2, neither was positive. These latter cases were, however, clinically typical enteric fever. Bleeding time and coagulation time determined in 3 cases after the onset of the vomiting showed normal values. Platelet count was normal. Prothrombin time was determined in 3 selected cases in which both the bleeding and coagulation times were normal. The figures were definitely prolonged in all the 3 cases.

All the 10 cases proved fatal. The average period of survival after the onset of this complication varied between a few hours and six days.

Case reports

Case 1.—Indian Christian, married female of 22 years, admitted on 5th July, 1946, with a history of continuous fever for 2 weeks, and had severe headache in the first week. Patient looked wasted, anæmic and toxæmic. Tongue coated and dry. P/R—120/28. Temperature 102°F., liver and spleen not palpable. No abnormality in the heart and lungs. Rose spots over the chest and abdomen. Laboratory findings: Hb. 32 per cent (Hellige), red cells 1.95 millions. W.B.C. 7,200. Polymorphs 64 per cent, lymphocytes 35 per cent, large monocytes 1 per cent, no malarial parasites, Widal T_H 1 in 150, urine and stool—no abnormality. On 6th, fever dropped to 97°F. and all the signs and symptoms of collapse appeared. Treated promptly with blood transfusion and other necessary supportive measures. Temperature rose and fluctuated between 101°F. and 103°F. General condition looked fair. On 10th, the patient passed a tarry stool and vomited once. The vomited matter contained blood. From 12th to 14th, the patient had two bouts of coffee-ground vomit each day. Temperature remained normal all these days. Patient developed slight jaundice. P/R—120/30 to 32. Bleeding time and coagulation time were 2 and 5 minutes respectively. Prothrombin time 44 seconds (normal control 22

seconds). The condition of the patient progressively deteriorated and she died on 15th. No autopsy was permitted.

Case 2.—An unmarried Hindu male, aged 20 years, admitted on 1st July, 1946, with a history of continuous fever for 3 weeks and severe headache in the first week. On examination, the patient looked anæmic and toxæmic. Tongue coated and furred. Temperature 104°F. P/R—112/32. Spleen enlarged 2 fingers, liver not palpable. Heart—N.A.D. Scattered rhonchi in both lungs. Laboratory findings: W.B.C. 4,500. Polymorphs 60 per cent, lymphocytes 38 per cent, large monocytes 1 per cent, eosinophils 1 per cent, no malarial parasites detected. Widal reaction and culture both negative. Urine and stool—normal. On 7th, temperature came down to normal but other conditions did not improve. On 11th, jaundice appeared and the patient got an attack of hæmatemesis. Bleeding time and coagulation time were within normal limits. Prothrombin time 38 seconds (control 25 seconds). On 12th, patient got 3 attacks of hæmatemesis and collapsed. Blood transfusion was given along with other supportive treatment but his condition went downhill and he expired.

Case 3.—Indian Christian, married female, aged 40 years, admitted on 12th July, 1946, with a history of continuous fever and headache for 9 days and passing tarry stools for 2 days. On examination, patient restless, general condition very low. Extremities cold. P/R—134/30, temperature 100°F. Tongue coated and dry. Abdomen soft. Liver and spleen not palpable. No abnormal sounds in the lungs. Heart sounds weak. Soon after admission, passed a stool with altered blood. Laboratory findings: Hb. 45 per cent, red cells 2.5 millions. W.B.C. 6,700. Polymorphs 68 per cent, lymphocytes 30 per cent, large monocytes 2 per cent. No malarial parasites found. Both Widal reaction and blood culture negative. On 13th, temperature became subnormal. Pulse imperceptible. Passed another tarry stool and started vomiting coffee-ground material. Death occurred the same day. Patient developed jaundice before death.

Case 4.—Hindu male, aged 19 years, single, admitted on 23rd June, 1946, for continuous fever and headache for 8 days. On examination, nutrition fair, tongue coated in the centre, edges raw, temperature 103°F. P/R—100/21. Liver and spleen not palpable. Heart—nothing abnormal. Lungs—a few scattered rhonchi. Laboratory findings: Hb. 72 per cent (Hellige). R.B.C. 3.5 million/e.mm. W.B.C. 5,062. Polymorphs 60 per cent, lymphocytes 35 per cent, monocytes 4 per cent, eosinophils 1 per cent. M.P.—not found. Widal para B 1/50.

Temperature continued a typical enteric course till 5th. On 7th, patient had nausea and hiccups. Temperature 99°F. P/R—98/26. Vomiting started. The vomited matter was watery at first, becoming bilious later. On 9th, the patient had a copious vomit, black in colour, occult blood

test in the vomit positive. General condition deteriorated. Temperature 98°F. P/R—110/26. Some purpuric spots appeared on the hands and forearm. Platelet count 250,000 e.mm. Died on 10th July.

Case 5.—An unmarried Hindu male, aged 23 years, was admitted on 25th July, 1946, for fever, headache, cough and vomiting of 4 days' duration. On examination, patient was fairly nourished. Tongue was coated in the centre and raw at the edges. Temperature 102°F. P/R—130/40, liver and spleen not palpable. Heart—N.A.D. Scattered râles in both lungs. Vomit was bilious in character. Laboratory findings: Hb. 70 per cent (Hellige), red cells 4.5 millions, no malarial parasites. W.B.C. 7,500. Polymorphs 65 per cent, lymphocytes 30 per cent, monocytes 4 per cent and eosinophils 1 per cent. Widal reaction was negative. Blood culture positive for *B. typhosum*. No abnormality in urine and stool. Vomiting persisted and on 30th July, 1946, contained streaks of blood. Occult blood test in vomit was positive. Bleeding and coagulation times were 4 minutes and 5 minutes respectively. Vitamin K was started. On 4th August, the temperature dropped to 97°F., P/R—96/32. In spite of this, the condition did not improve much and he now complained of pain in the epigastric region. Jaundice was noticed at this stage. Hæmorrhagic fluid was withdrawn from the stomach by Ryle's tube after which the viscus was washed out with sodium bicarbonate solution in warm normal saline. Prothrombin time determined at this stage was 1 minute 10 seconds (control 25 seconds). Vomiting of thick black fluid continued unabated and the patient died on 5th August.

Case 6.—An unmarried Anglo Indian male, aged 20 years, was admitted on 1st October, 1946, for continuous fever for 17 days. On examination, he was fairly nourished but toxæmic. Tongue coated. Temperature 103°F. P/R—116/30. Liver and spleen not palpable. Heart—N.A.D. Both lungs showed râles at the bases. Laboratory findings: Hb. 80 per cent (Hellige), red cells 4.2 millions. W.B.C. 9,062. Polymorphs 92 per cent, lymphocytes 6 per cent, monocytes 2 per cent, eosinophils nil. No malarial parasites found. Widal reaction T_H 1 in 150 and T_O 1 in 50. No abnormality in urine and stool. The patient ran a high temperature varying between 105°F. and 103°F., his toxæmia increased and on the third day of his admission he had two huge coffee-ground vomits. After this he became pulseless and died in spite of all treatment.

Case 7.—Hindu female child, aged 8 years, was admitted with a history of running a continuous high temperature for 12 days. She had intense headache at the beginning and bowels were constipated. On examination, her general health was fair though moderately anæmic. Tongue coated and moist. Abdomen was distended, the spleen and liver could not be palpated. She looked toxæmic. P/R—136/30

and temperature 105°F. Heart—N.A.D. Both lungs showed scattered râles and rhonchi. Laboratory findings: Hb. 60 per cent (Hellige), red cells 3.5 millions. W.B.C. 20,312. Polymorphs 78 per cent, lymphocytes 18 per cent, monocytes nil and eosinophils 4 per cent. No malarial parasites detected. Widal reaction was negative. A blood culture, however, showed *B. typhosum*. Urine examination revealed definite albumen with a few hyaline but plenty of granular casts. No abnormality in stools. Owing to high leucocytosis the patient was put on an alkaline diaphoretic mixture and adequate doses of M.&B. 693 tablets which were maintained for 5 days. The temperature dropped to 99°F. 8 days after admission, 20 days after the commencement of her illness and 5 days after M.&B. 693 administration.

Although the temperature declined, she still looked toxæmic and pale and her urine diminished in quantity. Two days later, she had a dark-coloured vomit and dark-coloured stool and died on the 11th day after admission.

Case 8.—A young boy of 8 years was admitted on 1st September, 1944, with a history of continuous fever for a week. The onset was insidious and attended with a great deal of headache. He had loose motions for 2 days prior to his admission into the hospital. Examination revealed a fairly well-nourished boy without anæmia or jaundice but definitely toxæmic. His tongue was typical, being coated in the middle and red at the margins. Temperature 102°F., P/R—120/30. Liver and spleen were not palpable. Heart—N.A.D. There were diffuse rhonchi and râles in both lungs. Laboratory findings: Hb. 70 per cent (Hellige), red cells 3.8 millions. W.B.C. 7,812. Polymorphs 60 per cent, lymphocytes 32 per cent, monocytes 8 per cent and eosinophils nil. No malarial parasites detected. Widal reaction negative. Blood culture was positive for *B. typhosum*. No abnormality detected in urine and stool. After running a typical course of a severe typhoid fever during the next 8 days, the temperature came down to normal by lysis and there was an all-round improvement noticeable in the patient's condition. On the 14th day after admission, i.e. after 3 weeks from the beginning of the fever while the temperature fell and the patient improved in every respect, jaundice developed suddenly. Four days later, the boy had two attacks of convulsions in the morning each lasting a few minutes. Then, all of a sudden, he had 3 attacks of coffee-ground vomit, his temperature rose to 104°F., unconsciousness supervened and death occurred in the same afternoon.

Case 9.—A Hindu male, aged 38 years, ran a continuous temperature for 15 days which was typically enteric in course. On the 15th day the temperature touched normal but he developed hiccup. Four days later, he developed œdema over the ankles. He was anæmic but there was no frank jaundice. Liver and spleen

were not palpable and there was no abnormality in the heart and lungs. Laboratory findings: R.B.C. 3 millions. Hb. 50 per cent (Hellige). W.B.C. 3,200. Polymorphs 69 per cent, lymphocytes 25 per cent, monocytes 4 per cent, eosinophils 2 per cent. M.P.—none found. Widal 1/250, blood culture negative. Urine showed a trace of albumin and bile; stool revealed plenty of giardia cysts and gave a positive occult blood test.

The temperature remained normal without much clinical improvement and on the 23rd day of illness he had an attack of hæmatemesis. This was soon followed by another attack of hæmatemesis and melæna and he died on 1st August, 1946.

Case 10.—A Hindu male, aged 30 years, had a continuous temperature for 5 weeks during which period Widal reaction and blood culture were both positive. He was treated as typhoid fever, and for the lung complication which developed during the illness, penicillin was used. The temperature was normal for 3 to 4 days after which it recurred again. Examination revealed a fairly well-nourished patient though he was looking pale and toxæmic. Temperature 104°F., P/R—130/34. No abnormality in the heart and lungs. Liver and spleen were not palpable. There was œdema all over the body with a little fluid in the peritoneal cavity. Widal reaction was positive. Towards the 50th day of his illness as the temperature gradually touched normal, he developed jaundice. Two days later, he got a bout of coffee-ground vomit, passed a tarry stool and in spite of all treatment died 4 days afterwards.

Comment

Typhoid fever being essentially a disease characterized by ulceration in the wall of the gut, hæmorrhage is often met with. The reason is obvious, because in the evolution of a typhoid ulcer, a blood vessel may be eroded. When such an accident occurs, the picture is characteristic, the severity of the symptoms depending on the quantity of blood lost within a given period. It is natural to expect such a bleeding at a time when the sloughs separate and the ulceration extends which events occur usually in the third week of the illness. The extravasated blood passes through the rectum and appears as melæna. There is no chance of this blood going upwards to the stomach to be vomited out. Given necessary treatment in the way of restoring blood volume and giving blood transfusion, patients usually get well and recovery becomes complete. The cases under review did not present any feature to resemble such a bleeding. It may be argued that a hæmorrhagic toxic gastritis may develop in the course of the infectious disease giving rise to the characteristic vomiting. Such a complication, if it develops at all, cannot explain all the details as revealed by our cases. Toxic gastritis should develop at the height of toxæmia and it would be difficult

to invoke such a complication when the course of the disease almost terminates or convalescence sets in. Moreover, jaundice often appears, either preceding or following the hæmatemesis.

It is a common experience of many of us in this country that the diet and dietetics in typhoid fever is very unscientific. The diet is not only deficient in calories, but in most of these cases, it also lacks in proteins, minerals and vitamins. When this defective dietary method is followed for a prolonged period, patients may develop œdema on the dorsum of the feet, puffiness of the face, and ulceration of the lips, angles of the mouth and tongue. It is in these patients that deficiency of other vitamins may make their appearance. Some of the vitamins are intimately connected with the coagulation factor of the blood whilst the other is responsible for the tone and permeability of the capillary wall. In those patients who are kept on such a poor diet, the deficiency of the latter vitamins is likely to manifest symptoms of defective coagulation mechanism of the blood with diminished prothrombin time of the plasma as well as altered permeability of the capillary blood vessels. Thus, hæmorrhagic oozing from the mucous membrane of the stomach and intestine begins which soon comes out as hæmatemesis and melæna. In order to corroborate their ideas, the writers are estimating the prothrombin time as a routine in typhoid fever cases using snake venom method. Cases with prolonged prothrombin time do not necessarily end in hæmorrhage although most of the cases who subsequently developed hæmorrhage had prolonged prothrombin time. Whether this hypoprothrombinæmia may have any rôle to play in the causation of these hæmorrhages is a matter for speculation. More work on this line may throw some light on this problem. The causal relationship of vitamin P with these hæmorrhages is also a matter for consideration. In case no. 4 in our series, there was purpuric hæmorrhage on the skin. It appears therefore that some part is also played by the lack of permeability vitamin in these cases producing an extravasation of blood in the stomach and intestine—a condition resembling symptomatic purpura having developed. More observations on these lines are necessary before any definite conclusion can be reached.

What rôle is played by the liver in these cases cannot be definitely stated. It will be found that many of the cases in this series developed jaundice either before or soon after the hæmatemesis and melæna started. It is known fairly well that in typhoid infection the liver may be variously damaged and focal necrosis and damage to the hepatic organ often take place. The jaundice which appeared in these cases was probably the result of a toxic hepatitis and under such circumstances the liver function may be depressed very much producing low plasma prothrombin and prolongation of the prothrombin time. If such a hypothesis be correct, tendency

to spontaneous bleeding can be easily explained; when the symptoms of hæmatemesis and melæna once start, the condition of the patient deteriorates progressively. The death is usually due to cardiac failure consequent on loss of blood. It will be noticed that none of the cases reported above survived even after transfusion of blood and administration of adequate doses of vitamins.

Summary

1. Ten cases of enteric fever having developed hæmatemesis and melæna as unusual complications are reported.

2. Clinically, jaundice which is known to be a very rare occurrence in typhoid fever developed in these patients either before or after such a hæmorrhage started.

3. Condition of the patients deteriorates progressively and rapidly in spite of all treatment, a fatal termination occurring in 2 to 3 days.

4. A diet with low calories, biological proteins and vitamins is a very important predisposing factor producing amongst other bad effects a deficiency of vitamin K and vitamin P leading to marked changes in the coagulation mechanism of the blood and the tone and permeability of the capillary wall. A severe damage of the liver produced by the enteric fever is perhaps responsible for such a derangement of the coagulation mechanism, the maintenance of which is one of the important functions of the hepatic organ.

The writers are indebted to the Superintendent, Medical College Hospitals, for his permission to publish the records of some of the cases and also to the house physicians for their ungrudging help in the management of some of these desperately ill cases.

INTRAVENOUS PALUDRINE IN MALARIA

By K. BASU MULLICK

Chief Medical Officer, Ludlow Jute Mills
and

J. C. GUPTA

Professor of Pharmacology, School of Tropical Medicine, Calcutta

WITH the advent of paludrine which has been reported to be superior to all known anti-malarial drugs, the use of it as a routine measure against malaria was started from July 1947 among the industrial population of the Ludlow Jute Mills which is situated at Changail in the district of Howrah. As usual the incidence of malaria in the place started rising up from the month of July. The population of the mill is about 5,000 and consists of people of Bengal, Bihar, Orissa, U.P., Madras, Ganjam and Bilaspur. Certain sections of the mill labour, particularly those from Madras, U.P. and Bihar, insist on having an injection whenever they are acutely ill from their previous experience with

mepacrine injections. So we thought of utilizing this drug by the parenteral route which has not been hitherto used by any of the previous workers as far as we are aware. To start with the drug was tried by intramuscular route on two cases but, as the patients complained of pain and tenderness at the site of injection as with mepacrine injections, the intravenous route was resorted to.

Preparation of the solution.—Paludrine is soluble in water in a concentration 1 in 50. The solution was made in normal saline in bulk. Five hundred tablets (= 50 grammes) were dissolved in 2,500 c.c. of normal saline. The tablets disintegrated and dissolved quickly with constant stirring. The solution was allowed to remain in a tall jar for 24 hours to allow the binding materials to settle down leaving a clear supernatant fluid which was siphoned off and autoclaved for 30 minutes under 20 lb. pressure.

Enquiries at the Imperial Chemical Industries who are the manufacturers reveal that they have not yet placed in the market any preparation for parenteral use. They have however a preparation under trial.

The class of cases.—All the cases were residents of the company's coolie lines situated within about 800 yards of the mill hospital. The cases were selected after proper clinical or laboratory diagnosis and for facility of observation.

Only 50 cases form the subject-matter of this preliminary report. They were of the following categories :

Group A : Acute malaria cases	32
Group B : Acute relapses of chronic malaria .. .	18
Total ..	50

All patients were adult workers and their ages ranged between 19 and 52 years : 41 were males and 9 were females.

Group A.—Acute malarial fevers—total cases 32.

In this group cases were again selected and subgrouped in the following manner :

(a) Those cases in which fever came on alternate days with or without chill. There were 11 cases in this group—usually a case had his 2nd, 3rd or 4th attack before the treatment was given. The temperature range was from 102 to 105°.

(b) These are cases of first attacks of typical clinical malarial ague. There were 21 cases. There was no enlargement of spleen. The blood films were examined with the following results :

B.T. found in	15 cases.
M.T. found in	3 cases.
No parasites	3 cases.

Temperature range of these cases was from 102 to 105°.

Group B.—Chronic malarial cases with acute relapses. There were 18 cases. All had varying degrees of splenic enlargement and had invariably more than one attack. The temperature range was between 102 and 105°. Many of these were known patients of recurrent malaria.

Technique of treatment by injection.—15 c.c. of the paludrine solution (= 300 mg. of the drug in normal saline) described above were injected into a vein at the bend of the left elbow slowly. For the first few cases lying down for about 10 minutes after the injection was advocated but as these patients did not complain of anything except the needle prick at the site of injection subsequent patients were allowed to go away after a few minutes. In all these 50 cases there was no immediate reaction whatsoever.

Results : Group A.—Of the 32 cases 5 showed persistence of temperature ranging between 100 and 102° on the 2nd day after the injection. These were as follows from subgroups—

(a) Clinically typical cases—2.

(b) Malarial ague cases confirmed by laboratory test—3 (all these were B.T. infection).

In these cases a second intravenous injection of 15 c.c. was given on the 2nd visit next day and they all became afebrile on the 3rd day.

The remaining 27 cases of group A became afebrile on the 2nd day after the injection and were quite fit.

Group B.—Everyone of the cases of this series had become afebrile on the 2nd day of the injection.

Subsequent treatment of all these cases, both groups A and B, consisted of giving them paludrine, 1 tablet three times a day by mouth, until a total dose of 12 tablets was attained and on completion of this course two tablets per week on set days at spaced intervals.

Paludrine by mouth (defective tablet).—The paludrine tablets as marketed at present disintegrate in the air into a powder and on account of this drawback cannot be dispensed the total dose for the full treatment conveniently to labourers at one time. So we dissolved the tablets in water in the same manner as for intravenous use and made up a solution in the strength of 1 tablet per one or half ounce of water flavoured with Aqua. Menth. Pip. and coloured with orange dye. This was dispensed in bottles in the time-honoured paper-marked foolproof style. This solution was taken three times a day and particularly suited those patients who had any degree of chronic trouble of the upper bowels. In other cases where there was no stomach trouble the patients were given 3 tablets to swallow at once, when they came for the 2nd visit. This was repeated on the 3rd and 4th days. In these cases a few doses of an alkali bromide diuretic mixture were given during the day.

After effects of the intravenous injection.—During the treatment with paludrine two

symptoms were reported by some patients namely varying degrees of anorexia and insomnia. Anorexia was reported by 4 patients (8 per cent) while insomnia by 6 per cent. Whether these symptoms had anything to do with intravenous paludrine is very difficult to say. Regarding anorexia it is worth mentioning that a large percentage of the mill hands are suffering from a form of chronic gastritis due to use of adulterated food.

Further experiments using 4 tablets of paludrine in 20 c.c. are being carried out and results will be published on the completion of a large number of cases.

Conclusion.—Paludrine solution can be used intravenously with good results as an anti-malarial agent. This method may well be utilized when the oral administration of the drug is not practicable.

P.S.—These observations were completed by the end of July 1947 and at the time of writing (end of August). The patients have been taking 2 tablets a week and had no relapses so far.

SEROLOGICAL TECHNIQUE (contd.)

By S. D. S. GREVAL

LIUTENANT-COLONEL, late I.M.S.

(From the Laboratory of the Imperial Serologist and Chemical Examiner to the Government of India, School of Tropical Medicine, Calcutta)

DETAILS OF COMPLEMENT-FIXATION IN KALA-AZAR AND LEPROSY

ADDITIONAL APPARATUS: (1) Soxhlet apparatus, (2) sand bath, (3) glycerine bath, (4) condenser, (5) reflux condenser.

ADDITIONAL CHEMICALS: (1) pyridine, (2) glycerine, (3) acetone, (4) benzol, (5) lecithin.

The Technique

The hæmolytic system.—This is taken from the LCF reaction. The complement is preferred in this order: (1) one of optimal titre and reaction, (2) one of high titre and optimal reaction, (3) one of high titre alone, and (4) one of optimal titre alone. *Complement of other qualities is not used.* This linking of the reaction with LCF is important.

The antigen.—The extract for making the antigen is essentially a solution in benzol of the (i) alcohol insoluble, (ii) pyridine soluble, and (iii) acetone insoluble fraction of the human tubercle bacillus. It can be bought as the WKK (Witebsky, Klingenstein and Kuhn) or prepared as follows:—

1. **The culture of the bacillus.**—At least 12 cultures, on glycerine agar, from 6 cases, grown for 2 months, are scraped and used as one lot.

2. **The bacterial mass.**—For the last stock of the extract made by the author 12 tubes and 1 Roux flask were scraped. The scrapings were suspended in 50 c.c. saline and autoclaved for $\frac{1}{2}$ hour. The killed bacilli were collected on double filter paper and dried in a desiccator for 2 days (constant weight not necessary). The weight was 1.078 grammes.

3. **Extraction with alcohol.**—27 c.c. of alcohol (20 times by weight) were added to the dried mass which was extracted with a reflux condenser over a water bath for 3 hours. The bacilli were again collected by filtration and dried in an incubator. The weight of the dried mass was 0.788 gramme. This was the alcohol insoluble fraction.

4. **Extraction with pyridine.**—The dried mass was extracted in a 50 c.c. Soxhlet apparatus with pyridine for 5 hours over a glycerine bath at 130°C. From the pyridinic solution the solvent was removed by distillation over a sand bath. The weight of the dried residue was 0.1652 gramme. This was the alcohol insoluble and pyridine soluble fraction.

5. **Extraction with acetone.**—The residue was extracted with 20 c.c. of acetone with a reflux condenser over a water bath for 3 hours. The acetone solution was filtered off. The residue on the filter was washed with 3 c.c. fresh acetone and dried in an incubator. The weight of the dried mass was 0.076 gramme. This was the alcohol insoluble, pyridine soluble and acetone insoluble fraction.

6. **Solution in benzol.**—The residue was dissolved in 7.5 c.c. of benzol in a small pestle and mortar (total quantity made up after evaporation due to exposure) to give a 1 per cent solution. The solution, unlike the commercial preparation, was milky. 15 c.c. of benzol were added by instalments of 5 c.c. to obtain a clear solution. The further addition of benzol is a departure from the original technique.

7. **Addition of lecithin.**—To two parts of the benzolic solution was added residue from one part of a 1 per cent alcoholic solution of lecithin. This was the desired extract for making the antigen. The antigen made from it agreed with the antigen made from the commercial extract in every way.

The extract keeps indefinitely when stored in a cool and dark place. If stored in a refrigerator it is taken out a day before the test and left at room temperature overnight. If not perfectly clear the next day it is left for half an hour in an incubator at 37°C. The quantity of the extract needed for a day's work, for 12 to 24 tests, need not exceed 0.2 c.c.

A new extract is considered fit for use only when the antigen prepared from it fixes complement with the titrated controls of pooled serum from cases of kala-azar to the limit of their reactions.

For making the antigen, evaporate a small volume of the extract (0.2 c.c.). Make the

residue, free from smell, into a uniform suspension, in pestle and mortar, with saline twice the volume of the original liquid (0.4 c.e.). *This suspension is the starting point.* From it prepare dilutions of 1 in 10, 1 in 20, 1 in 30, 1 in 40, 1 in 50 and 1 in 60 and test for anti-complementary activity with 1 MHD of complement, thus :—

Tube No. :—	1	2	3	4	5
Antigen dilution 1 vol. of 1 in :	20	30	40	50	60
1 vol. of complement containing :	1 MHD	1 MHD	1 MHD	1 MHD	1 MHD
Saline :	1 vol.	1 vol.	1 vol.	1 vol.	1 vol.
Left at room temperature $\frac{1}{2}$ hour and in incubator $\frac{1}{2}$ hour.					
Sensitized rbc suspension :	1 vol.	1 vol.	1 vol.	1 vol.	1 vol.
Left in incubator $\frac{1}{2}$ hour. Result read as +, T, \pm , ? —, and —, immediately.					

The strongest dilution of the antigen permitting an almost complete hæmolysis of the rbc (?—) is the required dilution for the test and one volume of it is the dose : for instance, if the 1 in 50 dilution permits the hæmolysis the dilution for the test should also be 1 in 50 (made from the suspension which is the *starting point*) and one volume of it is to be the dose. As in previous determinations of MHD in the presence of the antigen, the tube showing the hæmolysis should just fall short of the crystal clear and ruby red tube giving the MHD of the complement acting alone. When two tubes are alike choose the one with the stronger dilution.

The dose should not be hæmolytic. Three volumes added to one volume of rbc should not hæmolyse the latter in $\frac{1}{2}$ hour at 37°C.

The strength of the required dilution varies with samples of the extract and lies usually between 1 in 40 and 1 in 60, but may be higher or lower. It is not determined on every day of work but simply confirmed by adding 1 volume of the dilution to 1 MHD of complement and 1 volume of saline, incubating the mixture, and adding 1 volume of sensitized rbc which should be hæmolysed on incubation. It may be determined every two months or so, specially with the change of seasons.

The dose is in excess of the needs of the reaction. With a constant dilution of a constant positive serum the reaction does not weaken with a gradual decrease in the antigen until the dose is halved.

The serum : 1. *Under test.*—It is inactivated at 55 to 66°C. and diluted 1 in 20.

2. *Known positive.*—Six positive sera when available are pooled, filtered and preserved. Titrated positive controls, giving + and T, in a 1 in 100 and a 1 in 200 dilution respectively or in stronger dilutions, are prepared as in the case

of LCF. The preserved serum need not be re-inactivated unless it has turned anticomplementary.

3. *Known negative.*—This should also be available from other tests.

Charging of tubes.—Only two tubes, one for the serum control and one for the test proper, are required and charged.

A column

1st and 2nd row tubes contain serum, 1 in 25, 1 volume and complement 2 MHD contained in 1 volume.

2nd row tube. Antigen dilution, 1 volume.

1st row tube. Saline (no antigen), 1 volume.

(Antigen and complement are mixed and delivered as a double volume after the serum has been delivered.)

Left at room temperature and incubated as in LCF.

Sensitized rbc, 1 volume added.

Incubated $\frac{1}{2}$ hour.

A negative control is put up in the same way.

If an LCF for syphilis is being done on the serum the same day, the serum control may be omitted. The serum control in the LCF test, even if \pm in a 1 in 5 dilution, will serve as a fully hæmolysed tube for this test.

Titrated positive controls, *two tubes for test proper*, are also put up, thus :—

A column

All tubes contain complement 2 MHD contained in 1 volume.

3rd row tube with : Serum 1 in 200, 1 volume. Antigen dilution, 1 volume.

2nd row tube with : Serum 1 in 100, 1 volume. Antigen dilution, 1 volume.

1st row tube with : Serum 1 in 100, 1 volume. Saline (no antigen), 1 volume.

Mixing of antigen and complement, first incubation, addition of sensitized rbc and second incubation as before.

As in the LCF the titrated positive controls indicate the constancy of the reaction from day to day and make small differences comparable. They are not indispensable for an occasional test.

Reading of results.—This is done immediately and next day as in LCF.

Complete inhibition of hæmolysis ..	=	+
A trace of hæmolysis ..	=	T
More than a trace of hæmolysis ..	=	±
Hæmolysis almost complete ..	=	?—
Hæmolysis complete ..	=	—

Record and report, and significance.—With only two tubes record and report are simple procedures :—

Serial number	Tubes		Result	Report
	1st row	2nd row		
I	—	—	—	Negative.
II	—	?—	—	Negative.
III	+	+	Anticomplementary.	Nil. (To be repeated in weaker dilution.)
IV	+/T	+	Anticomplementary.	Nil. (To be repeated in weaker dilution.)
V	—	+	+	Positive.
VI	—	T	±	} Doubtful.
VII	—	±	±	

Anticomplementary sera in kala-azar are frequent and their anticomplementary titre is the highest anticomplementary titre known to the author. Dilution, as in complement-fixation in general, reduces this titre much more rapidly than the antibody (or reagin) titre.

The significance of + and — is equal and high in kala-azar. A negative reaction in a case of fever of over two weeks' duration is not compatible with kala-azar. A positive reaction is given only by: (1) kala-azar, (2) leprosy, (3) some cases of dermal leishmaniasis, and (4) some cases of pulmonary tuberculosis. The last two conditions can be excluded easily, clinically.

The significance is also high in nodular leprosy. It has been said that cases of this type of leprosy do not require much aid in diagnosis beyond a microscopic examination of the lesion. Taking blood, however, is a much easier process than removing bits of the body for the microscope. Besides, a determination of the end-point of the reaction is capable of measuring improvement, spontaneous or resulting from treatment.

The aid given by the test in neural leprosy is not of a high order.

Testing weaker or stronger dilutions.—The 1 in 25 serum dilution was arrived at by selection from a large range of dilutions. In this dilution only the two diseases mentioned above may sometime interfere. They are excluded serologically by testing a 1 in 100 dilution. As a

matter of fact, it saves time in the end if one uses two dilutions for the test always, thus :—

A column

All tubes contain complement 2 MHD contained in 1 volume.

3rd row Serum, 1 in 100, 1 volume.
tube with : Antigen dilution, 1 volume.

2nd row Serum, 1 in 25, 1 volume.
tube with : Antigen dilution, 1 volume.

1st row Serum, 1 in 25, 1 volume.
tube with : Saline (no antigen), 1 volume.

Other procedures as before.

Only a + in the 3rd or 2nd tube is accepted as a positive reaction. If both tubes are positive the reaction is 'Positive, strongly'.

Stronger dilutions (1 in 5 and 1 in 10) are employed after the failure of the standard 1 in 25 dilution in early stages of kala-azar and in nerve leprosy, and for observing improvement in nodular leprosy and kala-azar, thus :—

A column

All tubes contain complement 2 MHD in 1 volume.

3rd row Serum 1 in 10, 1 volume.
tube with : Antigen dilution, 1 volume.

2nd row Serum 1 in 5, 1 volume.
tube with : Antigen dilution, 1 volume.

1st row Serum 1 in 5, 1 volume.
tube with : Saline (no antigen), 1 volume.

Only a + in the 3rd or 2nd tube is accepted as a positive reaction which is reported 'Positive in 1 in 10' or 'Positive in 1 in 5'.

Paradoxical reaction.—This is seen occasionally and usually in the strong dilutions of a strong serum. Attention is called to it when the stronger of the two dilutions give a weaker reaction, as below :—

A column

3rd row tube with : Serum 1 in 10 Reaction T

2nd row tube with : Serum 1 in 5 ±

1st row tube with : Serum 1 in 5 (and no antigen) —

The reaction would be called doubtful but for the paradox. On diluting the serum further a + reaction is obtained.

In view of such a possibility it would be wise to test all sera in two dilutions always.

Two doses of complement versus 2 dilutions of serum.—That a differentiation between + and T, towards the end-point of the reaction of positive serum in the LCF in syphilis, can be made more often with a decrease in serum than an increase in complement is established by the titrated positive controls in that reaction, thus :—

Tubes :	1st	2nd	3rd	4th
Serum dilution :	1 in 50	1 in 100	1 in 50	1 in 100
Antigen :	1 vol.	1 vol.	1 vol.	1 vol.
Free complement :	2 MHD	2 MHD	4 MHD	4 MHD
Reaction :	+	T	+/T	T/±

Arithmetically the fixation in the 3rd tube should equal to that in the 2nd tube. Actually it is always more even when incomplete. The 3rd tube should yield a T reaction but as often as not it yields a + reaction. The 2nd tube in which the serum has been decreased is more reliable as a control and in keeping with expectation than the 3rd tube in which the complement has been increased.

In a strong reaction if a differentiation between two tubes can be made it should be made.—Such a differentiation probably not of much importance in establishing a diagnosis is invaluable in observing improvement.

Observations on the Technique

The sensitiveness of the reaction.—The sensitiveness is of a very high order. Like the strongly positive LCF of secondary syphilis the reaction cannot be missed or masked by any error or irregularity which is likely to creep into a serological procedure. Because of this high degree of sensitiveness T is not considered better than \pm . For the same reason ?—is grouped with —.

The specificity of the reaction.—While there is ample excuse for using the term specificity in connection with the reaction of the sera of lepers with the antigen, because of the group relationship between *M. tuberculosis* and *M. lepræ*, the use of the term in connection with the sera of kala-azar patients is not justified. In the latter case the reaction is undoubtedly non-specific like the LCF reaction in syphilis and has probably a similar immunological basis: a reagin arising from processes of allergy (not an antibody arising from processes of immunity) happens to fit into an antigen-like substance and needs the aid of complement for the completion of the process. The diagnostic aid, however, is of a very high order, comparable to that given by the LCF in secondary syphilis.

Special features of the technique.—There are five such features: (1) the antigen is linked to the MHD of the complement, its dose being the

maximal non-anticomplementary amount. (2) The serum is tested routinely in a dilution of 1 in 25. In this dilution interference caused by other diseases is minimal. (3) The dose of the complement is small and constant. Difference in reaction is brought out by increasing or decreasing the serum. This plan (i) detects paradoxical reactions and (ii) differentiates between + and T better than an increase in complement. (4) Complement of a poor quality, as determined in its titration in the LCF for syphilis, is not used. This restriction on the complement ensures obtaining of repeatable results in weak reactions. (5) Titrated positive controls are used, when available.

Repetition of the Reaction

For technical reasons: 1. *When the titrated controls are available.*—Their correct reaction guarantees the correctness of a \pm reaction which need not be repeated.

2. *When the titrated controls are not available.*—From what has been said concerning the preference for the qualities of the complement, it follows that a doubtful reaction not in accordance with clinical expectation or not giving enough aid in diagnosis should be repeated with a complement of a better quality (if an inferior quality has been used before) in order to obtain more fixation. This is necessary in view of the fact that adjustment like those in the LCF are not made in this reaction.

The repetition is also indicated when the MHD of the complement selected for the LCF has given a fixation rather on the low side in that reaction.

Enough serum should be available for the repetition from the original sample. If a fresh sample be necessary the preparatory measure of taking the blood early in the morning, before any food has been taken—if ignored previously, should be enforced now.

For observing the course of the disease.—Fresh samples will, of course, be necessary for observing increasing or decreasing fixations.

(To be continued)

A Mirror of Hospital Practice

A CASE OF HERNIA LUNG

By ASITA LAL SOM, M.B., F.R.C.S. (Edin.)
Teacher of Clinical Surgery, Campbell Medical School,
Calcutta

HERNIA of the lung is rare, so the following case deserves publication.

G. C. P., cultivator, aged 35, Hindu male, was admitted to my ward with a painful visible swelling on coughing over left anterior chest of four months' duration.

The patient stated that he was gored by a bull over that part about five months ago. Immediately after the injury he noticed a local swelling. He was febrile for about a week. The local swelling subsided in a month's time, followed by the present swelling. There was no history of hæmoptysis after the injury.

On examination.—There was an oval swelling about three inches long with its long axis horizontal, visible on coughing over the left third and fourth intercostal spaces in front (see figure 1, plate XXVII). During quiet breathing

there was a depression over the area, and the swelling would reappear on forced expiration. The swelling was crepitant and reducible. A small gap could be felt through the third intercostal space near costochondral junction. On pressing the gap and then asking the patient to cough, the swelling would not appear. On auscultation vesicular breathing could be heard over the swelling. X-ray examination of chest did not throw any light on the lesion apart from the fact that there was displacement of the third costochondral junction. Under intratracheal gas oxygen and ether anaesthesia the swelling was explored. The pectoral muscles were split when the hernial sac was exposed. The pleural sac was adherent to the overlying muscle and was accidentally opened while freeing adhesions. The neck of the sac was about two inches wide. There was no adhesion between visceral and parietal pleura. When the pleura was opened, positive pressure anaesthesia was used. The neck of the sac was closed with interrupted catgut stitches. The gap in the chest wall was closed by transplanting the lower rib by breaking it in the middle and raising the anterior end. The anterior end of the transplanted rib was fixed by two catgut stitches passed through drill holes to the periosteum of the rib above (see figure 2, x-ray photograph, plate XXVII). The wound was closed in layers.

The operated area was strapped for three weeks. Recovery was uneventful. The case was followed for about two months. There was no recurrence. Patient complained of dragging pain over the site of operation during extreme abduction of the left shoulder.

Comment.—Hernia of the lung or pneumocele is a bulging of lung tissue through a deficiency of chest wall during expiration. The bulging is either through an intercostal space or through a gap between the broken ends of a rib over the front and lateral aspect of chest. It may be

congenital or acquired in origin. If acquired it may be spontaneous in old emphysematous patients or after an injury.

Clinically it is usually reducible, but it may be irreducible if there is adhesion between visceral and parietal pleura at the neck. If the bulge takes place in inspiration it means diaphragmatic injury. Strangulation is very rare.

The swelling may be confused with cold abscess, angioma, empyema necessitatis, lipoma or diaphragmatic hernia with protrusion of abdominal viscera. If there is doubt x-ray examination after A.P. may be of value in diagnosis. Treatment may be conservative with a truss in old patients. When operation is decided closure of the chest wall is the important part of the operation. One should avoid opening the sac for chance of late adhesions. This patient was complaining of pain at the site of operation, probably due to adhesion. Closure of the wall over the gap may be done by reflecting pieces of periosteum, fascia lata strips or by transposition of ribs without complete resection. The results of these operations are usually satisfactory. This patient experienced some dragging pain during extreme abduction of the shoulder probably due to fibrosis in the pectoral muscles which will ease out in due course of time.

I am grateful to Major E. A. Lossing, M.D., I.M.S., for allowing me to report this case.

This case was demonstrated in a clinical meeting at the School of Tropical Medicine, Calcutta.

CLINICAL USES

I. Early syphilis

THE modern treatment of syphilis by arsenic, bismuth and penicillin is followed by very favourable results, provided that it is commenced in the early stage and maintained regularly. Any delay renders cure less likely. It is, therefore, of the utmost importance to

establish the diagnosis before the patient becomes Wassermann positive, and this can only be done with certainty by finding *Treponema pallidum* in the serum expressed from the primary lesions. Of the arsenicals neoarsphenamine (NAB) or mapharside should be relied on and the others are to be used only in special circumstances, but short courses as given in the old days are useless. Three or four courses of half a gramme of NAB per stone body-weight are a fair average—that is, a ten-stone man requires about five grammes in each course. But we cannot depend on arsenicals alone, they must be reinforced with bismuth which also has to be given in long courses. We must remember, too, the importance of persisting with treatment for the

standard period even though serological negativity has been obtained quite early. Treatment is, therefore, a lengthy process, extending over a year even when it is begun in the sero-negative primary stage. This is the greatest obstacle to treatment as many patients fail to co-operate. Owing to this reason there have arisen short-intensive methods of treatment which seem to give good results though it is too early to anticipate their remote effects.

(a) *Intensive treatment with mapharside*

NAB is not used owing to the frequency of toxic symptoms. The dose of mapharside varies according to weight, being approximately 1 mg. per kg. body-weight or 60 mg. (0.06 gm.) for an average man. It is suitable only for early cases and the patients should be young and free from visceral disease or dermatitis. If severe toxic symptoms develop the course must be interrupted and less intensive methods adopted. The most serious complications are agranulocytosis and hæmorrhagic encephalitis. The treatment demands frequent examination of urine and white cell count.

1. *20-day treatment*

Injections of mapharside daily for 20 days and of bismuth on alternate days for ten days. As there is much greater risk of toxic effects than in other methods, the technique should only be employed where skilled supervision and nursing are available.

2. *10-week treatment*

Mapharside three times and bismuth once a week. This is much less toxic and can be used in ambulant cases.

(b) *Semi-intensive 26-week treatment*

It is known as *alternating continuous treatment* in which mapharside (0.06 gm.) and bismuth (0.2 gm.) are given alternately but without any rest intervals. It is now used in the U.S. Army and Navy. It consists of (1) 10 weeks of biweekly mapharside injections followed by (2) 6 weekly injections of bismuth and then (3) another course of mapharside for 10 weeks and in addition (4) weekly bismuth during the first five and last five weeks of the period of treatment (26 weeks).

(c) *Conservative standard treatment*

This is the *intermittent and concurrent* system commonly used in England in which NAB (0.6 gm.) and bismuth (0.2 gm.) are given concurrently by weekly injections for ten weeks followed by four weeks' rest. As a matter of convenience bismuth may be administered a few days after arsenic. Four such series of injections are given to sero-negative cases and five series to sero-positive cases of early syphilis. The total course extends from 52 to 66 weeks

but may have to be varied according to the age and sex of the patient.

In the U.S.A. it is customary to give *alternating continuous treatment*. One such schedule consists of five courses each of arsenic and bismuth. Each arsenic course consists of eight weekly injections and is followed by one of bismuth, the first bismuth course consisting of four injections, the second of six, the third of eight and the fourth and fifth of ten each, the whole treatment being completed in 78 weeks. If mapharside is used the injections should be given twice weekly.

(d) *Treatment with penicillin*

According to one treatment schedule which has been used extensively, the total dosage is 2,400,000 units given in 60 doses of 40,000 units each dissolved in 2 c.c. sterile saline. It is injected intramuscularly every three hours day and night so that the course is complete in seven and a half days. As a significant proportion of cases so treated have relapsed, other methods are being tried, and one of them is the use of 4 to 5 million units of penicillin given over the same period and combined with arsenic and bismuth. This combination has proved superior to penicillin alone. One schedule of this combined treatment is the usual dosage of penicillin followed by ten weekly injections of arsenic and bismuth. Another scheme now under investigation consists of mapharside 0.04 gm. injected once daily for four days, followed by penicillin beginning on the fifth day. Treatment is concluded with bismuth subsalicylate 0.1 gm. given every fifth day for ten doses. It seems that as an adjuvant bismuth is more important than arsenic. Some cases after the first day of treatment with penicillin show the Herxheimer reaction with fever and exacerbation of local lesions; this is a transitory phenomenon and is ordinarily no indication for discontinuing the treatment. Apart from this, the drug produces none of the severe toxic reactions formerly associated with antisyphilitic treatment.

Choice of remedies

The old standard treatment with NAB and bismuth covering a year or more is safe, ambulatory, and with few exceptions applicable to all stages of syphilis, but many patients default owing to its long duration. The toxicity of the intensive methods is inversely proportional to the time in which they are given, i.e. the shorter the intervals of injection the greater the chance of poisoning the patient who in such cases must undergo the treatment in hospital under skilled supervision. Indeed, the intensive methods should be adopted only by those with some previous experience. The short-term results of the 26-week treatment have been reported to be very good and may replace the old conservative treatment, but the intensive and semi-intensive treatments should not be

applied to late syphilis or latent and congenital cases. It seems, however, certain that penicillin will ultimately prove to be the drug of choice in combination with arsenic and bismuth, but we must await the results of the investigations that are now proceeding. It is very likely that longer experience will produce some simplification of present methods of administering penicillin. The various methods are tabulated below :—

Drug	Total dose	Duration of treatment	Remarks
1. Penicillin	2.4 mega units	7½ days	Safe. Dose not satisfactorily settled yet. Should be combined with arsenic and bismuth.
2. Mapharside and Bismuth	1.2-1.6 gm. 2.0 gm.	20 days	Danger of toxic effects. Hospitalization.
3. Mapharside and Bismuth	1.8-2.4 gm. 2.0 gm.	10 weeks	Much safer than no. 2.
4. Mapharside and Bismuth	2.4 gm. 3.2 gm.	26 weeks	Safe.
5. NAB and Bismuth	20-24 gm. 8 gm.	52 weeks	Safe. Can be given in all stages of syphilis. Risk of default.

After care

When early syphilis is adequately treated the Wassermann reaction returns to normal in the vast majority of cases, but it is essential to maintain regular clinical and serological observations for a period of two years. The Ministry of Health, London (Memo., V, 21, 1944) recommends the following procedure: 'After completion of treatment the blood should be tested every three months for the first year and every six months in the second one. After each visit a thorough clinical examination should be made. The spinal fluid should be tested at the end of treatment, or earlier if the blood reactions are resistant and the test should be repeated at the end of the two years of observation which are regarded as minimal. In the case of females, satisfaction of the above tests is not considered to be a sufficient safeguard against infection of the foetus in the event of pregnancy, and treatment throughout the period of gestation should be advised'.

Sero-resistant cases

When all tests become negative and remain so for two years the patient may be considered to be cured. The Wassermann reaction is a good guide to treatment, but there are difficulties in interpreting results and in cases of doubt a

specialist should be consulted. A few cases are sero-resistant when the treatment may be repeated preceded by fever therapy. This may be induced by intravenous injection of mixed typhoid vaccine (T.A.B.) beginning with 25 million organisms and working up to 100 millions or more, at intervals of five days. Malaria therapy or a hypertherm apparatus is superior but not suitable for general practitioners. Some advise a change of drugs, but penicillin has not proved very effective in such cases. When however it is used it should be given in conjunction with bismuth. Too much importance should not be attached to positive Wassermann as long as the spinal-fluid is negative and there is no clinical relapse. Some of these reactions spontaneously disappear with longer periods of observation. Finally, it is essential in all such cases to carry out quantitative serological tests as such an estimation may reveal a greater improvement than is apparent from a qualitative test alone.

II. Late or tertiary syphilis

In tertiary syphilis there is no uniform clinical picture and the treatment is influenced by many factors such as age of the patient, state of heart, liver and other vital organs, and tolerance to antisyphilitic drugs. In these late cases complete eradication is probably impossible and much harm may be done by injudicious energetic treatment. In general treatment should be mild in intensity but prolonged and intermittent and the general health of the patient should be the principal guide and not the result of the serological test. One should begin with iodides which are of great value especially in gummata. NAB is given only after preliminary iodide therapy, but it is important to begin with small doses and not to exceed moderate amounts. The patient should be under treatment for four years and under observation for a longer period. During the first two years he receives every three months a course of arsenic and bismuth and iodides between these courses, and during the next two years courses of mercury and iodides thrice a year or of bismuth twice a year. When arsenic is considered unsafe as it may be in some elderly patients bismuth and mercury may be relied on. Intravenous injections of arsenic should not be given to patients over 60 years old.

A pregnant woman should be energetically treated when the health of the child is the main consideration.

Patients with liver disease tolerate arsenical drugs poorly and are first treated with iodides and bismuth for three months and then with arsenic of which not more than two courses should be given in a year. Cases of renal disease are started with iodides, then small doses of an arsenical drug and as recovery proceeds moderate doses of bismuth preparations are given. Use of penicillin in late syphilis has been referred to in the previous article.

PROTEIN DIGESTION RESTORED BY BOVRIL

Conclusive result of medical experiments

In many illnesses, when gastric secretion is impaired and is deficient in hydrochloric acid, Bovril corrects this condition by restoring the normal volume and activity of the gastric juice, thus aiding the peptic digestion and absorption of protein foods.

In 1911, the late Professor Thompson, of Dublin, established that Bovril had the power of ministering to nutrition by the assistance it gave to the assimilation of other foods. Recently a remarkable series of experiments has been conducted at an English University. A group of medical students volunteered to undergo the unpleasant experience of allowing the passage of an œsophageal tube into the stomach so that accurate studies might be made of the effect of certain beef preparations. One of the substances investigated was Bovril.

As a result of these experiments (described in detail in the *British Medical Journal* of August 28th 1937) Bovril emerged as 'the most effective stimulant.' Briefly, it was proved that Bovril increased the supply of gastric juices where there was a deficiency and restored it to normal. It is an accepted medical fact that people of sedentary habits generally suffer from a lowering of the essential gastric activity; Bovril rectifies this and, by facilitating the digestion of proteins, enables full nourishment to be gained.

Everyone, therefore, who is run down through strain or illness, or who feels in need of extra strength to cope with the demands of modern life, should take a cup of hot Bovril daily. It is a delicious and stimulating way of keeping fit and strong.

BOVRIL

STIMULATES DIGESTION

THE RELIEF OF DIGESTIVE DISTURBANCES

In the treatment of digestive disturbances especially where there are indications of gastritis, peptic ulcer, cholemesia and other sequelae of hyperacidity, Cal-Bis-Ma will provide an excellent antacid particularly useful in the treatment of these pathological conditions. This preparation has pronounced sedative action upon the inflamed mucosa of the digestive system, and provides alkaline medication in a form palatable alike to children and adults.

CALSIMIL

Trade Mark

Calcium Sodium Lactate with Vitamin D

Calcium deficiency is attributable either to lack of dietary calcium or to lack of vitamin D. A number of secondary factors may be responsible for these primary deficiencies and thus account for the widespread incidence of calcium deficiencies.

Calsimil, which contains calcium sodium lactate and vitamin D, is an ideal preparation for the correction of calcium deficiency, for it not only supplies the substances lacking but also provides for the absorption and retention of the calcium. In addition, Calsimil tablets are palatable and acceptable to patients of all ages and can be readily administered by dissolving in milk for infants or they may be sucked or swallowed whole by children and adults.

Stocks of Calsimil are held by leading chemists and full particulars are obtainable from—

SERIES 2

OF THE WATSON MASS MINIATURE RADIOGRAPHY APPARATUS

THE first series of Watson apparatus for Mass Miniature Radiography was approved and recommended by the Medical Research Council, and adopted as the standard equipment in the Government Mass Radiography Campaign.* It attained a high level of technical excellence, and proved to be completely reliable, many millions of exposures having been made by the units in service.

The second series whilst retaining the well-tried features of the original design, embodies several improvements (many of them suggested by users) which render this Watson apparatus even more convenient in use and undoubtedly the most efficient mass miniature radiography unit available today.

Other Watson X-ray apparatus is of equally high standard; please write for catalogues.

NOVEMBER

STREPTOMYCIN

THIS antibiotic has recently been available in India and has been free from extraordinary restrictions one could have imagined to have been imposed on its delivery from well-guarded stocks. A Calcutta firm, now out of stock, supplied all *bona fide* customers. The usual permits were obtained from the head of the medical department in the province. The Haffkine Institute, Bombay, had supplies sent direct from America.

A Calcutta practitioner of repute has used the antibiotic in three cases of tuberculous meningitis and feels 'neither satisfied nor dissatisfied'. With the pre-streptomycin line of treatment he would have felt dissatisfied undoubtedly. Tuberculous meningitis is the disease which has first claim on streptomycin.

The usual non-committal, if not actually pessimistic, remarks have lately given place to words of encouragement in America. 'In a case of tuberculous meningitis associated with miliary tuberculosis complete clinical arrest followed a long and intensive course of streptomycin therapy. The drug was well tolerated and there were no neurologic residua' (Appelbaum and Halkin, 1947). 'Streptomycin administered early in the course of tuberculous meningitis is capable of arresting the process' (Mehas and Truat, 1947).

The substance is an antibacterial agent produced by the mould actinomycete, *Streptomyces (Actinomyces) griseus*. It was first isolated and reported by Waksman three years ago (Waksman, 1944). Occurring as a base (in contrast with penicillin which occurs as an acid) it is converted into a salt, sulphate* or hydrochloride. The salt is a white powder stabler than penicillin and its solution can be sterilized by heat (Wilson, 1947). It lends itself to be referred to in terms of weight better than penicillin. One gramme of pure streptomycin base equals 1,000,000 units and one microgramme, therefore, equals 1 unit (Editorial, 1947a).

The antibiotic activity of the salt is assayed in a manner similar to that of penicillin. The original unit was defined as the quantity which completely inhibited the growth of a strain of *Escherichia coli* (*Bacillus coli* of the easier nomenclature) in 1 c.c. of nutrient broth.

The antibiotic activity is shown against a variety of gram-negative and gram-positive bacteria both *in vitro* and *in vivo*. The list

includes *Escherichia coli*, *Proteus vulgaris*, *Aerobacter arogenes*, streptococci, staphylococci, Friedländer's group of bacilli, *Pasteurella tularensis*, *Brucella abortus*, *Eberthella typhosa*, *Mycobacterium tuberculosis*, *Hamophilus influenzae* and the last but not the least *Pasteurella pestis*. The effective concentration of the drug in the blood can be maintained by 4-hourly (probably even 8-hourly—Wilson, loc. cit.) intramuscular injections. It also lends itself to other forms of administration like penicillin.

The action on *Pasteurella pestis* is of special interest to us in India. Experimental animals have been saved with certainty and serious human cases of plague have recovered (Sokhey, 1947, personal communication; Karamchandani and Rao, 1948). The rapidity with which improvement sets in, specially in animals, has not been seen before under any other line of treatment. The human case requires altogether 6 grammes of the drug ($1\frac{1}{3}$ gramme every 4 hours) and the cost at present is 2 dollars a gramme. In its claim on the drug plague comes a good second, the pneumonic form of it being bracketed with tuberculous meningitis. The price is bound to come down and thanks to the stability of the compound may be some day as low as that of penicillin.

Reports on the use of streptomycin in tuberculosis were summarized some time ago (Editorial, 1947b). Half the cases of tuberculous meningitis are saved from death and cases of pulmonary tuberculosis are benefited. The former category, unfortunately, may include the blind, the deaf or those otherwise seriously affected by damage to a part of the brain. In this connection it has been suggested that the physician should not wait for all the signs of tuberculous meningitis for a diagnosis. The brain damage then would be slight.

Other tuberculous affections such as cold abscesses, sinuses, urogenital tuberculosis and bone disease have been treated with the antibiotic successfully (Brook, 1947).

Urinary infections not controlled with sulphonamides and penicillin have been controlled with streptomycin.

Experimental syphilis in rabbits (Johnson and Adcock, 1947), and penicillin resistant and sulphonamide resistant, specific and non-specific urethritis (Pulaski, 1947) have also been treated successfully with streptomycin.

Ocular infections of all kinds have also been treated successfully by local application and injection (Bellows and Farmer, 1947).

Not much is known of the action of the antibiotic in whooping cough and leprosy. By all calculations it should act.

In spite of absence of encouraging reports the antibiotic may be used in empyema (even tuberculous), peritonitis and cholera, or any infection with gram-negative organism. In fact, in view of its low toxicity, all forms of acute infections may be treated with it, in addition to the usual treatment.

* Streptomycin sulphate Squibb is supplied in 25 c.c. vials in an amount equivalent to 500 mg. of the pure streptomycin base.

In two respects the drug differs from penicillin markedly: (1) It exerts a selective toxic action on the 8th cranial nerve causing tinnitus and/or vertigo. This is likely to occur and in fact does occur in the treatment of meningitis when the drug is used for months. For other conditions the toxic action does not come into play. The tinnitus and vertigo are not permanent. (2) The micro-organism under attack is likely to become resistant to the drug if the dosage is inadequate. Such an effect caused difficulties in the early days of penicillin too. The difficulties disappeared with the greater availability of that drug. The tendency is definitely greater in the case of streptomycin. The interference, however, is only academic and can be overcome easily except in the treatment of tuberculous meningitis.

Since writing the above, we are informed that the drug has again become freely available in Calcutta. Streptomycin sulphate Upjohn is supplied in vials containing the equivalent of 1 gm. (1,000 mg.) of the pure base.

CORNEAL GRAFTING IN INDIA : ITS DIFFICULTIES

By VICTOR C. RAMBO, M.D., F.A.C.S.

Christian Hospital, Mungeli, C.P., India

THROUGH many years attempts, mostly unsuccessful, have been made to give sight by grafting corneas. Filatov of Odessa (1935) was the first ophthalmologist to report doing considerable successful corneal grafting and to establish it as a practical procedure. Other reports of work followed: Thomas of Cardiff (1938) conducted many experiments and made the procedure a not unusual one in Britain. Castroviejo of New York (1941) was a contemporary and others have taken up the work until it is now often a successful operation, if all of the rules of the procedure are carefully followed, an operation that has helped hundreds of people to better sight.

Corneal grafting is an operation which aims to replace opaque or malformed (as keratoconus) cornea with normal cornea from another eye. Tudor Thomas's investigations have proved definitely that corneal grafting must be done from an eye of the same species. He has proved that heterogenous grafts, i.e. grafts from donors of other species than the recipients, are worthless. Corneas from eyes enucleated for other eye diseases not involving the cornea or eyes from a person who has recently died or even from an infant dying at birth can be used. After removal from the body the eye must be kept at a temperature of 2°C. until use. It is best not to keep the graft more than 48 hours after death and it is better to use it as soon as possible.

My experience in India with the operation has been one of desire and not of accomplishment, and I have not had complete conviction concerning its use except in well-chosen cases.

In the late thirties I was treating a youth with interstitial keratitis from congenital syphilis. A happy result followed. We brought him with specific and fever therapy produced by intravenous typhoid-paratyphoid vaccine from a visual power of counting fingers only at half a metre to the point of successfully completing his college matriculation with 6/6 vision with his refractive correction. During this time I saw in one clinic in a like opacity from interstitial keratitis, a neat central corneal graft with the patient seeing through the graft enabling her to get around independently. A beautiful immediate result. To the distress of the surgeon the newspapers made much of it. A recent visit to the same city now shows that the interstitial keratitis has entirely cleared up from the cornea surrounding the graft and the only opacity is now the central graft which is white, round and exactly demarcated.

During my 1936-37 furlough I talked with Castroviejo and saw some of his square grafts made with his special two-bladed knife. He emphasized, whether knife or trephine was used, the importance of care in choosing a recipient eye for grafting. If there are blood vessels running into the opacity, or secondary infections in the conjunctiva or cornea, or anterior synechia, or glaucoma, or too much scar, one cannot expect success. The corneal tissue of the host, he went on to say, must be sufficient to support the corneal tissue of the graft.

What a battery of demands from a villager who comes in with opacity and demands immediate operation. In my experience it appears that nearly every scar of the cornea has blood vessels to nourish it. The healthy uninjured cornea has a circulation without blood cells, but scar tissue is different. Nearly any scar that is deep enough to disallow peeling off of the scar surgically will have blood vessels running into it, and these can be seen if they are looked for with a loupe, to say nothing of looking for them with the slit lamp microscope.

Somerset of Calcutta points out that the 'majority of opaque corneas in India are due to leucoma adherens. If it is a small leucoma adherens, I think that optical iridectomy is the operation of choice. Where there is a really large leucoma adherens and no clear cornea for an iridectomy you will usually find there is hardly any anterior chamber and no anterior chamber in the centre. Furthermore, in this case the lens is cataractous and largely absorbed. The result is that on drilling out your disk of opaque cornea you go straight on to the vitreous, and in my experience these cases never do much good. However, there are enough cases in which the eye is normal, except for an opaque cornea to make it well worth while doing the corneal grafting operation. In those cases in which one eye is normal, it seems to me that the majority of patients will not get much benefit from a graft on the other eye, because I think the percentage of grafts that remain transparent are very few. We do the operation although there are many difficulties. It is extremely difficult to get donors. We usually take the recipients into hospital and make them wait until a suitable donor turns up and consequently they sometimes have to wait for months'.

I feel that ordinarily it is not fair to the patient to do a corneal grafting operation on an only eye that can be helped into the sighted world with an iridectomy. And the eye that cannot be helped with an iridectomy because of extensive scarring is one that has substantial blood vessels coming in from the limbus, from one or more directions and insufficient corneal tissue to support the new corneal tissue of the graft. Well-directed use of radium may extend the possibility of corneal grafting by making scarred corneas not fit for corneal grafting into corneas where the grafting may be feasible. Lane (1931) 'advocates its use in the treatment of corneal ulcers and claims that it stimulates healing and lessens scar formation through its action on the new-formed connective tissue cells, which are more sensitive than the corneal cells'. Kilgore continuing, 'Radium was recommended as a means of inhibiting the formation of fibrous and vascular tissue by Lane (1931) and Hilgartner and Hilgartner (1933), both in 1931. Iliff uses contact therapy on the invading vessels at the limbus, four to five gram seconds of Beta and Gamma radiation if they are large, and a spray therapy if the vessels are fine and superficial. This consists of passing the application back and forth over the area, giving ten to twelve gram seconds at one treatment repeated within a week. The newly peeled cornea is not exposed to radiation'.

One day a youth of 17 years appeared with a one-eyed corneal opacity ideal for a graft. Though there were a few small vessels going into the scar, I could not imagine finding a scar with fewer or smaller vessels. For three weeks we waited for a donor eye. The youth slipped

away without even the iridectomy that would have helped him a little.

This spring a painful aphakic blind eye with a reasonably good cornea for grafting presented itself in the possession of a fairly well-to-do woman who demanded relief from the pain in that eye. We put off enucleation, and for a week we looked at every person with opacity as a possibility for receiving a graft from the cornea of this eye to be removed. Finally, the woman would wait no longer and with regret we took the eye out and put it into the refrigerator hoping that the next forty-eight hours would bring in a recipient eye. But after forty-eight hours, the eye was turned over to the pathologist. We did not want to wait the full seventy-two hours, some say it is possible to wait, before using the cornea, but even seventy-two hours brought no recipient eye.

On the train to Kodaikanal just a few days ago I met a man from the police force who had read about the corneal grafting in other countries and asked whether I was doing the operation or not. 'It is wonderful, wonderful!' he said, 'It captures the imagination'. And it does. 'Where can I get donors?' I asked. 'So few people with blind eyes, eyes that are useless and even dangerous to leave in, are willing to be donors. They defeat every effort of reason or persuasion'. 'Perhaps eyes of those executed in prisons could be used,' suggested the police official. 'But', he went on, 'usually the relatives take the body'. And that seemingly put an end to that possibility.

I have returned from America with a 5-mm. and a 6-mm. trephines for the cornea graft operation. The parallel knives of Castroviejo are less used than previously, being replaced by the less technically difficult trephines. In skilled hands, on suitable eyes, given suitable grafts, the percentage of useful takes is fairly high. We are ready to use the method to restore sight, we hope soon.

In recent years an eye bank has been developed in several places. This is an organization which canvasses the public and finds donor eyes to give to those doctors who are doing the corneal grafting operation. A good many people have written into their wills a clause which states that when they die their eyes may be used for the corneal grafting procedure.

Can we have an Eye Bank for Sight Restoration such as the one established in New York City? At first only twenty ophthalmologists acted as advisers and interpreters on the programme. Now two hundred and thirty-seven doctors are serving throughout the nation. Instead of the twenty-two hospitals participating there are now seventy-eight hospitals taking a part in the programme. Quoting further from an Editorial on the Eye Bank (1946) 'Transportation for incoming and outgoing eye material has been made available through the co-operation of the American Red Cross and various

airlines. In addition to supplying corneas for surgical procedures, the eye bank has carried on a widespread programme of education both of the public and of physicians through the press, magazines, the radio and the distribution of literature'. Concluding the Editorial states: 'Challenging research problems which have been attacked include studies of corneal preservation, technique of transplanting the vitreous humour and investigation of the metabolic and histologic properties of the eye. An information kit of educational material may be obtained by writing to the Eye Bank for Sight Restoration, Inc., 210 East 64th Street, New York. 21.

If all men and women, officials and public, knew the need, eyes could be made available in India. Some persons would, as in other countries, put a clause in their wills that after death their eyes are to be used to give sight. The press can help greatly in this matter but particularly an organization modelled on the Eye Bank for Sight Restoration, backed up by The All-India Ophthalmological Society and the Indian Red Cross Society.

Experienced Indian eye surgeons particularly younger men who have shown outstanding ability should be given scholarships to take special courses in the eye surgery of corneal grafting in places where this operation is a common procedure.

All ophthalmologists should report their cases, successful and unsuccessful, in medical meetings and medical journals. Statements referring to successes should be guarded, knowing that an immediate success may not be a success, after a month or a year. If the information as to the source of material for grafting could be pooled the profession would be guided as to the best methods of obtaining suitable eyes.

Conclusion.—In India, especially in the interior, it is difficult to find ideal recipient or donor eyes for transplanting corneas. It is very difficult to find both recipient and donor eyes at the same time.

Further efforts should be made by all eye surgeons to do the corneal grafting operation as often as practicable. Experienced surgeons should be given scholarships for study of the techniques of corneal grafting.

The All-India Ophthalmological Society and the Indian Red Cross Society should develop, with some clinic or clinics where successful corneal grafting is being done, an organization such as the Eye Bank for Sight Restoration. A philanthropic person, or organization, could scarcely find a cause more fruitful in giving happiness.

If donor eyes are found and furnished, surgeons can go ahead with the finding of recipient patients. Surely, this important method of restoring sight should have full development in India with its hundreds of thousands of blind from opacities of the cornea.

L.T.M. EXAMINATION, 1947

The following candidates are declared to have passed the L.T.M. Examination held on the 6th October, 1947, and subsequent days:—

Passed

(Arranged in alphabetical order)

- Parimal Kumar Chanda, L.M.F. (Bengal), Private Practitioner.
 Hari Pada Chowdhuri, L.M.F. (Bengal), Private Practitioner.
 Brojendra Kumar Das Gupta, L.M.F. (Bengal), Assistant Medical Officer, Central Hospital, Borjuli Tea Estate, Assam.
 Mulshanker Motiram Dave, L.C.P. & S. (Bom.), Assistant Medical Officer, Lunawada State Dispensary, Bombay.
 Anil Krishna De, L.M.F. (Bengal), Private Practitioner.
 Jitendra Nath Ghosh, L.M.F. (Bengal), Private Practitioner.
 Robindra Kumar Ghosh, L.M.F. (Bengal), Private Practitioner.
 Chandi Charan Goswami, L.M.F. (Bengal), Private Practitioner.
 Jiban Ranjan Lahiri, L.M.F. (Bengal), Assistant Medical Officer, Borengajuli Tea Estate, Assam.
 Amal Kumar Mitra, L.M.F. (Bengal), Private Practitioner.
 Sukumar Mitra, L.M.F. (Bengal), Private Practitioner.
 Vinayak Vishwanath Paranjpe, L.M.F. (C.P.), S.M.S., Government of Bombay.
 Rasamoy Paul, L.M.F. (Bengal), House Surgeon, Bankura Medical School Hospital.
 Harirao Vishnupant Pophale, M.B., B.S. (Hyderabad), Private Practitioner.
 Katangur Prabhakar Reddy, M.B., B.S. (Hyderabad), Private Practitioner.
 Jyoti Bhusan Roy, L.M.F. (Bengal), Private Practitioner.
 Hirendra Kumar Saha Chowdhury, L.M.F. (Bengal), Private Practitioner.
 Naresh Chandra Sen, L.M.F. (Bengal), Private Practitioner.
 Jnanananda Sinha, L.M.F. (Bengal), Private Practitioner.
 Rash Mohon Talukder, L.M.F. (Bengal), Private Practitioner.

MEDICAL INSTITUTIONS IN U.K. CROWDED ADVICE TO INDIAN STUDENTS

(Being a press note issued by the Ministry of Health, Govt. of India, dated 17-11-47)

It has been brought to the notice of Government of India that many Indian medical students and doctors have proceeded to the United Kingdom for studies without first assuring themselves of admission to British hospitals and colleges. They expected to obtain admission in those institutions, but have not been able to do so, because at present U.K. hospitals and colleges are crowded with British war-returned personnel.

In view of the very limited number of vacancies available in such institutions persons intending to take up medical studies, whether post-graduate or otherwise, are advised not to leave India until they have obtained admission to the institution where they intend to prosecute their studies.

QUARANTINE RESTRICTIONS

(Being a press note dated 29-11-47 issued by the Director-General of Health Services, Govt. of India)

INFORMATION has been received by the Director-General of Health Services that the health authorities in Malayan Union have imposed quarantine restrictions on account of cholera against passengers from India.

In order to avoid being placed in quarantine on entry into Malayan Union, passengers leaving India for that country by sea and air are strongly advised to be in possession of cholera inoculation certificates showing that inoculation has been performed not less than six days and not more than six months prior to arrival in Malayan Union. The certificates should be in the international form.

EFFECT OF DDT ON PLANT LIFE

(Issued by the Press Information Bureau, Govt. of India, on 3-12-47)

In reply to a written question in the Constituent Assembly (Legislative) to-day, the Hon'ble Rajkumari Amrit Kaur, Health Minister, Government of India, said that there was no record of damage to foliage caused by DDT unless used dissolved in kerosene. She added: 'Dusts containing synthetic insecticides like DDT are sometimes used for plant protection. A great deal of experimental work is necessary to determine the extent of damage, if any, to plant life through adverse effects on pollination'.

RESEARCH WORK BY MEDICAL LICENTIATES

APPLICATIONS are cordially invited from Licentiate Doctors to undertake and conduct some research work in medicine, surgery and allied sciences likely to be useful from a treatment point of view. The applicant should kindly state (1) the problem of his research, (2) the location of his research with the facilities he has, (3) the period he might require to complete the research, and (4) the amount he might spend on it till its completion. The applicants are earnestly solicited to note that it should be purely a labour of love for the cause of Science and with a view to raise the Licentiate class in estimation of others.

P. H. SANT,

Secretary,

Scientific Committee, All-India Medical
Licentiates' Association, Bilaspur, C. P.

WORLD MEDICAL ASSOCIATION

(Abstracted from a note on the subject by Dr. P. B. Mukerji, President, Indian Medical Association, published in the *Jour. Ind. Med. Assoc.*, and from the editorial in the *B.M.J.*, 27th September, 1947, p. 498)

THE first initiative towards a world medical association was taken in 1946 when, under the joint auspices of the Association Professionnelle Internationale des Medecins and the British Medical Association, 33 medical associations in 31 countries sent their representatives to a 3-day conference held at the British Medical Association House in London, opening on 25th September. This conference, which was attended by over 40 full delegates and 32 observers, decided that there should be international liaison in the field of medicine and that an international organization should be brought into being to lend full support to the practitioners all over the world against the subtle and insidious forces which were menacing the age-old traditions and freedoms of the profession. Before breaking

up, this conference set up a provisional committee of nine members to work out a draft constitution and by-laws of the proposed association and to place same before a similar conference of representatives of national medical associations to be held at Paris in 1947 for consideration and adoption as the instrument governing its activities.

The second conference which held its sittings at Paris in the Domus Meshia, the Headquarters of the Confederation des Syndicats Medicaux Francais, from 17th to 20th September, 1947, was inaugurated by the French Minister of Health, who welcomed the delegates to the French capital and was attended by representatives from 48 national medical organizations. Throughout the proceedings the Confederation des Syndicats Medicaux Francais acted as a most generous host.

At the first part of the meeting, the delegates adopted the Draft Constitution and By-laws which were submitted by the Organizing Committee of nine, after suitable modification of some of the articles. The objects of the W.M.A. are contained in the following articles:—

- (1) To promote closer ties among the national medical organizations and among the doctors of the world by personal contact and all other means available.
- (2) To maintain the honour and protect the interests of the medical profession.
- (3) To study and report on the professional problems which confront the medical profession in the different countries.
- (4) To organize an exchange of information on matters of interest to the medical profession.
- (5) To establish relations with, and to present the views of the medical profession to the World Health Organization, the U.N.E.S.C.O. and other appropriate bodies.
- (6) To assist all peoples of the world to attain the highest possible level of health.
- (7) To promote world peace.

Membership of the organization is governed by Article 5 which was accepted in the following form:—

- (1) Those medical associations which sent delegates or observers to the International Medical Conference in London in September 1946; and
- (2) Any other national or territorial medical association which is fully representative of the medical profession in its country or territory or of the members of the medical profession of a recognized ethnic group in its country or territory.

The General Assembly which would be responsible for the general control and direction of the policy and affairs of the association would consist of delegates from the member-associations, each such association being entitled to appoint two delegates and to enjoy two votes, one for each delegate and two for one delegate, if the second was unable to be present. 'A delegate' it was decided 'shall be a person who is medically qualified and a member of the association he represents, and he shall be ordinarily resident in the territory of that association'. The Council which would carry into execution the resolutions passed by the General Assembly and administer the affairs of the association in accordance with the articles and by-laws, would be composed of the President, the President-elect, the Treasurer and ten members of the General Assembly elected at its annual meetings in the manner and for the period prescribed in the by-laws. It was decided that the English, the French and the Spanish would be the official languages of the Association and that a journal or a bulletin may be published periodically as decided upon by the Council. It is gratifying that India has obtained a seat in the Council, Dr. S. C. Sen, the Honorary General Secretary of the Indian Medical Association, who was one of the delegates, secured the third highest vote.

At the first meeting of the World Medical Association proper, which occupied the second half of the Proceedings, Dr. Charles Hill was appointed Acting Honorary

Secretary, Professor Marquis, Director of the School of Medicine at Rennes, was elected the first President and Dr. Routley the Chairman of the Council. The Treasurer, Dr. Leuch of Switzerland, in presenting his report pointed out that the funds from the subscriptions of the various national member-associations were inadequate for the tasks of the W.M.A. and reported to the meeting the generous offer made by the American delegates of \$50,000 a year for five years. To this gift certain conditions were attached, and because of these conditions feelings ran high. Briefly, they were that the money should be used for (i) the salaries of the Secretary and other officials of the clerical staff, (ii) the rent and rates of the headquarters office, and (iii) the cost of publication of the W.M.A.'s official bulletin or journal; also that the headquarters of the W.M.A. should be in North America, the exact location to be determined by Council and that the Council be instructed to work out a scheme of associate membership. Dr. L. H. Bauer, one of the delegates from the U.S.A., gave to the meeting a clear exposition of the circumstances of the gift. The money had been offered by friends of the A.M.A., principally industrialists, anxious to promote the interests of the W.M.A. The disbursement of the money would be under the control of a committee in the U.S.A. composed of five doctors and four laymen. If the business donors could be admitted under a scheme of associate membership, Dr. Bauer said, they should have the right to attend meetings but not, of course, the right to vote. The first speech of opposition to this proposal was made by Dr. P. B. Mukerji, President of the Indian Medical Association. He expressed his appreciation of the generosity of those who had made such a large sum of money available to the W.M.A. but doubted whether it should be accepted under such terms. He felt that the W.M.A. should work out its own salvation even if it meant that much of the work would have to continue to be done on a voluntary basis. The debate on this controversial subject continued on Friday. Irrespective of the conditions of the gift, it was decided that the headquarters of the Secretariat should be in North America. On the following day the General Assembly voted in favour of accepting the handsome gift of \$50,000 a year for five years. It is perhaps a commentary on the unsettled economy of the world that the W.M.A. which represents some 500,000 doctors could not raise sufficient funds to carry on its own work unaided.

After the business part of the meeting was over, the General Assembly took up for discussion two motions by Denmark and Great Britain and a document prepared by the Council of the British Medical Association entitled 'War Crimes and Medicine'. Prof. Charles Richet, a French medical victim who had spent some time in a German concentration camp, related his own experiences and was followed by one of the Greek delegates who described the brutalities committed in his country during the last war by members of the profession, acting under orders of the Nazi High Command. The Assembly listened in sympathy to these. It was finally agreed that German delegates should not be admitted to the W.M.A. until organized medicine in Germany condemned the past criminal acts of German doctors.

The following matters were also referred to the Council for appropriate action or investigation and report :—

- (i) The general arrangements for the organization and publication of a bulletin or journal.
- (ii) The preparation of a report on the enquiry into the present position of the medical profession in relation to the state.
- (iii) The motions of Luxembourg, supported by Australia, recommending the preparation of a comparative statement of standards of training for the medical profession and conditions of registration, and of a comparative statement on the qualifications of specialists.

(iv) The following motions by India : (a) That the Council be requested to study and report on the question of the advertisement of cures and medicines in the lay press, and (b) that the Council be requested to study and report on the question of unqualified and unauthorized medical practice.

(v) The preparation of standing orders to govern the procedure of meetings of the General Assembly.

(vi) The appointment of auditors.

The General Assembly decided to hold its 1948 meeting at Prague, the exact date to be fixed by the Council, and elected Dr. J. Stuckli (Czechoslovakia) as President for the year 1947-48.

The W.M.A. has set its hand to a great task, and if it is to achieve its highly important objects, it will have to secure the good will of the various national medical associations in all parts of the world. Much, of course, will depend upon the hard work, tact, and ability of the permanent Secretary, who is yet to be chosen.

PROCEEDINGS OF THE 2ND MEETING OF THE SURGICAL SOCIETY OF THE MEDICAL COLLEGE HOSPITALS, CALCUTTA

THE 2nd meeting of the Society was held on 11th October, 1947, at the Medical College, Calcutta, under the presidency of Dr. P. Chatterji, Prof. of Surgery. Dr. A. K. Basu read a paper on 'Care of spinal injury patients with paraplegia—A survey and report on 10 cases'. Dr. Basu mentioned the appalling mortality of this type of case—11 out of 15 cases treated in the Medical College Group of Hospitals during 1945-46 died and contrasted this result with that obtaining at the Ministry of Pensions Spinal Injury Centre at Stoke Mandeville, England. In his series of 10 cases, 5 patients died and only 2 could be got up on wheel chairs. He discussed the several problems facing a surgeon in charge of these cases. He differed from the current teaching of attempted hyperextension in spinal paraplegia except in G.S.W.s of the spine. In his opinion there is scarcely ever any indication for laminectomy or plaster fixation in spinal paraplegics. He advocated immediate suprapubic cystostomy and mentioned that the external cystostomy opening should be high up, small and the track oblique in order that leakage be reduced to a minimum. For cystitis and phosphatic incrustation of the bladder it was his practice to maintain acid reaction of urine and to wash out the bladder with 1 per cent acetic acid. Routine bladder irrigation was not employed. Small breakages of skin or superficial excoriations cannot always be prevented but with adequate and conscientious care from the nursing staff and with a leak-proof urinary fistula, it is possible to avoid large and penetrating sores. Recently skin grafting has been used to cover large granulating areas.

Maintenance of adequate nutrition was important and administration of high protein diet supplemented by prepared aminoacids when necessary was advocated. The physiotherapeutic part of the treatment involves prevention of contracture and deformity by use of light aluminium splints, passive movement of paralysed limbs and joints, massage and electrotherapy. Re-settlement of the paraplegics is a problem in which the state should help by instituting occupational therapy centres and special homes where the paraplegics, who are unfit to go back home, can be lodged.

In conclusion Dr. Basu reiterated his plea for a rational and humane approach to these unfortunate cases. He said that 'at least a partial solution of this problem lies in the centralization of such cases under one interested person, who will view their many problems with care and sympathy, who will direct, organize and stimulate and who by his own example—as well of those under him—will inspire the paraplegics, in spite of their disability, to be self-reliant and honourable members of society'.

A discussion ensued in which Dr. A. K. Roy asked whether hyperextension of these cases is ever indicated or necessary and mentioned a method introduced by an Edinburgh surgeon in which a long sand bag covered by bolster is laid transversely under the mattress and named by him 'Hyperextension mattress'. He also enquired whether suprapubic cystostomy was to be advocated in all cases with paraplegia or whether catheterization may be recommended for the first 2 or 3 days to see if spinal condition will show some improvement. Dr. U. C. Chakrabarty mentioned that in his experience it is almost impossible to get a leak-proof cystostomy. The President narrated his experiences of this type of case. He said that after doing 11 laminectomies in this type of cases, he was dissatisfied with the results and has given up this operation in spinal paraplegia. He agreed with Dr. Basu that violent methods of hyperextension are to be condemned and that immediate suprapubic cystostomy is the best. He enquired from Dr. Basu as to the most suitable time when these patients should be got up and he ended by reinforcing the plea for centralization of these cases.

Dr. Basu in reply reiterated his objection to violent methods of hyperextension and questioned whether the type of 'hyperextension mattress' that Dr. Roy mentioned would be of much use or would improve the nursing problem. In his opinion the high, narrow and oblique suprapubic track he described produces the minimum of leakage. About the time of getting these patients up, he said that the vertebral fracture dislocation must consolidate before one can recommend these patients to sit up and this usually takes 3 months. But after that time every effort must be made and every encouragement given to sit these patients up and to get them out of bed in wheel chairs.

At the end of the meeting a successful case of multiple tendon transplantation for complete musculo-spiral palsy was demonstrated by Dr. Basu.

INTERNATIONAL CONGRESS OF SURGEONS

40 COUNTRIES REPRESENTED AT LONDON MEETING

By G. V. T. CHURCH

(Reproduced from Release No. F953, dated 23rd September, 1947, issued by the British Information Services, New Delhi)

The largest gathering of surgeons seen for a quarter of a century has just concluded its deliberations in London. It was the 12th Congress of the International Society of Surgery, which opened on 15th September, and was attended by representatives from more than 40 countries.

Opening the Congress, Sir Alfred Webb-Johnson, President of the Royal College of Surgeons, said: 'By virtue of our calling we are patriots of humanity and know no frontiers. We are also ambassadors of our own countries and as such can help to promote peace, concord and understanding between nations'.

The Congress provided an opportunity for surgeons to pool their knowledge and to review the recent achievements of medical science. Overseas delegates were also provided with facilities to visit the London hospitals and to study their organization.

Physicians in Conference

Earlier in the month, London was also the scene of another conference of medical experts—the six-day International Congress of Physicians. This meeting was attended by no fewer than 1,300 delegates, representing 29 countries. Among those who went from India were Major Shone, I.M.S., Professor of Medicine at Andhra Medical College, Vizagapatam; Dr. S. M. K. Mallick of the University of the Punjab; and Dr. T. K. Babur of the Karachi Medical Association.

An important item on the agenda of the conference was Britain's contribution to the world in the form of penicillin. Its discoverer, Sir Alexander Fleming, opened the discussion. Describing the efforts made to simplify the administering of the drug, Sir Alexander

said that in the ordinary sense it was impossible to give an overdose of penicillin.

Dr. R. V. Christie of St. Bartholomew's Hospital, London, said that penicillin had revolutionized the treatment of bacterial diseases of the valves of the heart, which were almost 100 per cent fatal before the drug was discovered. Infection was now controlled in 93 per cent of the cases.

B.I.S. OFFICE IN CALCUTTA

(Reproduced from the Press Note, dated 22nd September, 1947, issued by the British Information Services, New Delhi)

A BRANCH of the British Information Services, Office of the High Commissioner for the United Kingdom in India, has been opened at 32, Chowringhee, Calcutta.

Mr. Brian Groves has been appointed Regional Information Officer and Mr. B. Dunelm Brown the Trade Information Officer.

A Reading Room which contains British periodicals has been opened in this office. This is open to the public from 9-30 a.m. to 5 p.m. on Mondays to Fridays and from 9-30 a.m. to 1 p.m. on Saturdays.

NURSING IN AUSTRALIA

By MARGARET LAWRENCE

(Reprinted from Release No. P/688. Issued by Australian High Commissioner's Office, New Delhi)

Most Australian nurses seeking work abroad have found that the high standing and standard of Australian nursing qualifies them for work in all parts of the world. The Registration Boards of the Australian States have reciprocal recognition with the General Nursing Councils of the British Isles and other parts of the British Empire where the training course covers at least three years.

The Australian Nursing Federation, which has branches in each State, is affiliated with the International Council of Nurses, and sent delegates to the Council's Congress in Atlantic City in 1947.

There are approximately 33,000 trained nurses working in Australia, of whom at least 28,000 are registered with the Nurses' Board of the six States. Present estimated shortage is 3,500 nurses.

The majority of trained nurses work in hospitals and institutions, but a large number are engaged in private and visiting nursing. Principal avenues for specialization are infant welfare work in such fields as Baby Health Centres, kindergartens and creches followed by public health, mental and industrial nursing. A limited number of nurses work in doctors' surgeries and laboratories, x-ray or radium clinics, or as air hostesses or ships' nurses.

The scattered nature of the population in the inland and the concentration of population in a few coastline cities make it inevitable that there should be vast differences of hospital and nursing conditions.

On the one hand, there are the 'Bush Nurses', who often work alone under conditions that require a great deal of self-reliance and initiative.

On the other hand, there are the great metropolitan hospitals, in which nursing staffs of several hundreds work in well-planned and equipped surroundings. American Army nurses who were stationed at the Royal Melbourne Hospital, which was lent to the U.S. Army from 1942 to 1944, agreed that the hospital and its luxurious nurses' home compared favourably in every respect with the leading hospitals in the States.

Training

Nurses' training is conducted at various approved hospitals in the capital and provincial cities. Only the larger hospitals have preliminary training schools. The training period for a general certificate is four years in New South Wales, Tasmania and Queensland. In the three other States the course was reduced to three years during World War II. On completing the course

and passing her final examinations a nurse becomes entitled to registration with the Nurses' Board in the State where she is trained.

During training the student nurse lives at the hospital and is provided with board and lodging; in most States uniforms are provided free. Laundry is done by the hospital. Hours worked vary between 44 and 48 per week.

Trainee nurses in Australia spend much more time in the wards than they do in U.S.A. and attend fewer lectures. The course of instruction, however, includes lectures in anatomy and physiology, general nursing, medical nursing, surgical nursing, hygiene and public health, materia medica, children's nursing, and invalid cookery.

Approximately 80 per cent of Australian nurses take also the nine months' midwifery course, and approximately 46 per cent take the three months' infant welfare course after completing their general training, though not necessarily immediately afterwards.

The Royal Victorian College of Nursing (the Victorian branch of the Australian Nursing Federation) is the only organization at present conducting post-graduate courses. Their course for Sister Tutors and Nursing Administration has been held in abeyance for the last two years pending government financial aid; the course will take one year (full-time) and will be held under the auspices of the University of Melbourne. The College also conducts a part-time course in industrial nursing, and arranges lectures for a Diploma in Nursing.

In most States courses may be taken for the certificates of the Royal Sanitary Institute, London, which includes health visits, school nursing and sanitary inspection. In New South Wales courses in paediatrics and tropical nursing may be taken.

University Status—Not Yet

In no States is nursing teaching affiliated with the Universities, which have not opened their doors as readily to the technical professions as those of the U.S.A. One of the immediate aims of nursing leaders in Victoria and New South Wales is the establishment of Nursing Colleges affiliated with the Universities and assisted financially by government grants.

Another aim is to increase the number of scholarships for post-graduate work. At present most nurses taking post-graduate courses have to spread them over several years. Scholarships are provided by the Australian Red Cross Society, the Florence Nightingale Memorial Fund and the Centaur Trust (in memory of Australian nurses lost when the hospital ship *Centaur* was torpedoed in 1943). About 20 Australian holders of such scholarships are at present taking post-graduate courses in England, mainly in hospital administration or sister tutor training at the Royal College of Nursing.

Nursing leaders believe that the nursing profession in Australia will not reach its peak of efficiency until uniformity in training, registration, remuneration and working conditions is achieved. At present these matters are controlled by six State governments instead of the Australian Federal Government.

Uniformity Aim

An Australia-wide conference of all nursing bodies will shortly be called by the Federal Minister for Health and Social Services, at which it is hoped that some progress towards uniformity will be made. Decisions of the Conference will not be binding on the States, however. Several leading nurses' organizations, such as the Royal Victorian College of Nursing and the Trained Nurses Guild, have prepared detailed plans for co-ordinating and organizing nursing services on a federal basis. One favoured plan proposes the appointment of a Director of Nursing, directly responsible to the Minister of Health, and a Commission of Nursing to work in conjunction with a Nursing Bureau.

Other vital questions are those of superannuation benefits and compensation for injury and sickness contracted while on duty. At present many of the large

metropolitan hospitals have system of superannuation, but it is by no means general throughout the profession. Public hospitals and many intermediate hospitals nurse their own staff free of charge. Other intermediate hospitals insist that their nurses join the Hospital Benefits Insurance Association, paying 3d. weekly. If the nurse becomes ill, the hospital takes the 2s. 2d. a week insurance money, and nurses her without any further charge.

Award Conditions

Of interest in the vexed problem of professional status was an interim judgment given by a judge of the Commonwealth Court of Conciliation and Arbitration in September 1945 that nursing was not an industry.

Wages, hours and conditions of work in each Australian State are regulated, either by Arbitration Court awards or by Wages Boards consisting of equal numbers of representatives of nurses and of hospital associations under an independent chairman. Conditions do not vary greatly in the different States, and the following determinations of the Hospital Nurses Wages Board in Victoria may be taken as typical.

Hours of work are 44 per week; but 88 hours may be worked in any two consecutive weeks, provided that overtime is paid for all work in excess of 48 hours in any such week. Staff nurses and trainees must receive three weeks' annual leave and all other employees four weeks, both with full pay.

Proportion of nurses to patients must not be less than one nurse to each 10 or fraction of 10 patients (day shift) and one nurse to each 15 or fraction of 15 patients (night shift).

Proportion of trainees to certified nurses must not be more than six trainees to each certificated nurse exclusive of the matron.

Wherever possible, single bedrooms must be provided; in no case shall more than two employees occupy the same bedroom. Separate accommodation must be provided for the night staff.

Rates of Pay

Board and lodging costs the hospital nurse only Rs. 43 monthly, which is deducted from her salary; an allowance is paid to her if she does not live at the hospital. Laundry is done free of charge, and uniforms, or an allowance for uniforms, are provided.

The following salaries (clear of the deduction for board) are the minimum that must be paid to some grades of hospital nurses in Victoria. The awards do not differ greatly in other States.

Trainee nurse, first year	Rs. 107-8-0
Staff nurse, first year	" 225-0-0
Sister, first year	" 270-0-0
Matron of hospital with 100 beds	" 375-0-0

Annual increments for second and third years range between Rs. 10-8 and Rs. 21 monthly. Any nurse who needs more than one certificate in connection with her duties must receive an additional Rs. 10-8 per month for each certificate required.

Private nurses receive Rs. 55 for a six-day working week, with a living out allowance of Rs. 20 to Rs. 24 per week.

Infant Welfare Nursing

There is a separate determination for infant welfare nurses, with additional provisions relating to allowances for travelling expenses. For instance, all out-of-pocket expenses reasonably incurred by an employee whose duties necessitate journeys and visits to various parts of the municipality are paid by the municipal authority concerned.

An outstanding feature of Australian nursing is the special care given to the younger generation, which has resulted in Australia's infant mortality figures being the second lowest in the world. During the five-year period 1935-39, Australia's infant mortality figures were 39 deaths per 1,000 births, as against 56 for U.S.A., 57 for England and Wales, and 70 for Canada.

American Army doctors and nurses stationed in Australia during the war made special visits to Australian mothercraft homes, where they saw what they described as 'miracles' performed in the treatment of babies suffering from feeding troubles.

Main difference between Australian and American infant nursing welfare practice is that Australians are strong advocates of breast-feeding wherever possible.

Unusually interesting and worthwhile work for nurses who like country-life is that of infant welfare nurse in the outback. Baby health nurses do a regular round of small country towns in the inland regions. They may travel in a caravan which is equipped as a Baby Health Clinic and Nurses' Living Quarters, or in a railway carriage, similarly equipped, which is attached to a train and uncoupled at a station then, after a scheduled time, recoupled and taken on to the next station. In other cases the nurse travels in a car, attending to mothers at halls or houses in the towns on her route.

Only a small proportion of infant welfare nurses work in the outback. The majority of work in the full or part-time Baby Health Centres run by suburban municipalities; or they may travel from one country town to another, the Centre at each being open on one or two days in the week only.

PATRIOTS OF HUMANITY

World's Doctors in Conference

By IAN COX

(Reprinted from Release No. F.981, dated 2nd October, 1947. Issued by British Information Services, New Delhi)

SURGEONS, by virtue of their calling, are all 'patriots of humanity and as such know no frontiers'. That was the keynote of Sir Alfred Webb-Johnson's welcome to nearly 500 surgeons from over 40 countries when they visited London for the 12th Conference of the International Society of Surgery. Sir Alfred is President of the Royal College of Surgeons, but had he been addressing the physicians as well, I doubt if he would have altered his words. The physicians had already begun their international conference and 13,000 doctors from all over the world were also in London.

Both conferences have been the first of their kind since the Second World War and of great importance because they provided an opportunity for free international discussion of the advances made in surgery and medicine everywhere during the last 10 years. In the province of surgery, several particular advances have been made within this period, and as soon as they are considered jointly, then open up completely new fields of surgical possibilities. The Conference has demonstrated how this applies, for example, to chest surgery.

Chest surgery

Until recently it was not possible for the chest to be opened successfully during an operation because, as soon as the negative pressure surrounding the lung was destroyed the lung would collapse. The development of intra-tracheal anaesthesia, perfected in Britain, has obviated this and it is now as practicable for a surgeon to open the chest as the abdomen. Basically, the method depends on the insertion of a tube into the trachea, an air-tight joint being provided by a collar round the outside of the tube. The air can then be fed into the lung down the inside of the tube from a bag-like arrangement at the distant end.

While this advance in technique has made the organs within the chest accessible to the surgeon, another development in quite a different field has greatly increased the use to which he can put his skill when once he has made such an access. This relates to the muscular system—the heart in particular—which recent work on an anti-blood clotting substance, called heparin, has rendered quite literally 'open to surgery'. A famous heart surgeon from Stockholm, who spoke at

the Conference, has employed this drug in his pioneer operation upon arteries.

Prior to its use, one of the dangers following an operation was pulmonary embolism caused by a clot of blood eventually coming to rest in the lung. This condition was responsible for fatalities of the order of two in every thousand. Now, by administering heparin to likely cases, the incidence is reduced to a minimum.

Control of blood clotting

This advance in the control of blood clotting, taken with that which rendered the chest accessible to the surgeon, has made possible the treatment of congenital abnormalities of the heart, hitherto eventually fatal to the child. These conditions result in the lack of blood in the lungs and in extreme cases produce what are known as 'Blue Babies'. At the Surgical Congress, it was described how pulmonary stenosis can be overcome by an operation that joins the normal portion of the pulmonary artery to the subclavian artery, thus short-circuiting the right of the heart and bringing increased supply of blood to the lungs.

The physicians also talked about the heart. Professor R. V. Christie of the Medical Research Council, for example, reported that penicillin had revolutionized the treatment of infective endocarditis which was about 100 per cent fatal before the discovery of the drug. Sir Alexander Fleming, the discoverer of the drug, described some of the research now being done to simplify its administration to patients. The main difficulty is that it is rapidly excreted by the kidneys; hence recent work has been aimed at slowing down its absorption.

The method that has the widest use at the moment is based on the incorporation of penicillin in an oil wax mixture which enables patients to maintain 300,000 units at a therapeutic level for as long as 24 hours. Formerly, it used to be given by continuous drip or by injections every three or four hours which was inconvenient both for the patient and the doctor. Excellent results have also been obtained recently with single daily injections of 500,000 units in watery solution and Sir Alexander Fleming considers that this may prove the most popular method of administering the drug.

Other contributions showed that the Medical Research Council is being very active in the investigation of antibiotics. Dr. Darcy Hunt, for example, is working on streptomycin. Of this, he said that early results are definitely encouraging and that the drug, in its pure state, is producing fewer toxic reactions, such as rashes and fevers; but there are still dangers attached to its uses.

AUSTRALIA'S OFFER OF ASSISTANCE

ANTI-CHOLERA VACCINE AND RED CROSS SUPPLIES

(Reprinted from Release No. P/682, dated 11th October, 1947. Issued by Australian High Commissioner's Office, New Delhi)

THAT the Australian Government has offered to supply anti-cholera vaccine free of charge to the Governments of India and Pakistan was confirmed to-day by the Australian High Commissioner (Lieut.-General Sir Iven Mackay).

The quantity mentioned as Australia's gift was 2,000,000 c.c.

Expressing the hope that fears for the spread of cholera would prove unfounded, Sir Iven Mackay said that Australians were deeply sympathetic with the many people in both Dominions suffering hardship and distress as result of the recent disturbances.

The Australian Red Cross also, he added, had communicated with Her Excellency Lady Mountbatten offering assistance, and asking her for guidance as to the type of relief most needed by distressed persons.

Sir Iven Mackay said that the Australian Government had already shown itself eager to arrange for a further increase in the shipment of wheat to India.

Public Health Section

SOME EXPERIENCES IN RURAL MEDICAL PRACTICE*

By V. ANANTACHARIU, L.I.M.
Vijaya Clinic, Nuzvid (S. India)

INDIA is said to contain seven lakhs of villages. Majority of the villagers in them are ill-educated. The villager, when his health deviates from normal, does not immediately apply for scientific consultation, either because such consultation is not always available or because it is not easily procurable for him; and yet the state of things is not allowed to Nature, which if unmeddled with, does correct matters in many respects. Various kinds of crude physical and mental treatments are resorted to. The following are some of the drugs with which the mofussil patient is drugged: (1) mercury in various forms as perchloride of mercury, calomel, crude mercury, *rasakarpoor*, etc., (2) opium, (3) thymol, (4) garlic, (5) *Calatropis indica*, (6) marking nut, (7) rubbing the cornea with copper coins, grass, etc., (8) asafoetida, (9) raw cattle dung as an application for scabies, (10) red hot cautery on various regions of the body of the patient in infantile convulsions. The patient gets in no way better but worse and in the end seeks admission for treatment to some scientific institution (if no further quackery comes in his way).

By the time the rural medical practitioner happens to see a case, very serious and grave complications have arisen. If the damage, to which some of the vital organs of the body are subjected, is not extensive such patients recover gradually but many cases of this nature become inevitably failures however skilfully one may try to restore order in the disturbed physiology of their systems.

The business of the rural medical practitioner has thus become more of prevention of complications than of treating actual diseases, when the village folk come under his observation. Almost all cases which apply to him for advice are to be treated in two ways: (1) antidoting for the various kinds of pills and potions administered during the previous handling of the cases and (2) from the disease point of view, we have a saying 'There is no man or woman who does not know about medicine and music'; the rural masses believe more in the layman's advice than in that of the schooled.

In infantile convulsions, instead of treating the cause of them (e.g. high temperature, intestinal parasite, nervous temperament, etc.), the infant is caught hold of and thrown into the air a

few feet high and again caught; it is brutally burnt with red hot iron on various portions of the body. Another malpractice among some communities is to cauterize the abdominal wall in various directions on the 3rd or 4th day after birth. The plea is that this treatment would improve its digestive function. As we all know the dangers of such hasty cauterizing are: (1) shock, (2) tetanus infection and (3) secondary infection from other organisms. A few escape, fortunately, from these dangers. The child cannot recover from the shock, and if by chance it recovers, the next danger is tetanus infection which brings on death in many cases.

In certain other instances, when a child was having convulsion, the juice of the leaves of *calatropis indica* was put in the nostrils of the baby in such a manner and dosage that the child developed deglutition pneumonia.

Crude mercury (*rasam*, *impure*) heads the list of drugs in the everyday practice of the village quack. Very few of his clientele actually escape poisoning with his dosage. The infant patients and young children under the age of ten years fortunately escape toxic symptoms in spite of the heavy drugging which is often resorted to for nearly 90 per cent of their complaints. But it is the unfortunate adult who cannot escape. The quack uses mercury in venereal diseases, arthritis of various kinds, diarrhoea, dysentery, 90 per cent of mofussil deliveries, fevers of various origin, for vague pains of the body during pregnancy, in cases of antepartum hæmorrhage, in paralysis and paresis of the limbs, etc. The dosage given is usually from $\frac{1}{4}$ to 1 tola in a single dose; or 6 to 12 grains continued for 15 to 20 days. The chain of symptoms of mercurial poisoning manifested by these patients is as follows: stomatitis, foetid smell from the breath, spongy, swollen, red, bleeding gums, and increased salivary secretions; nephritis, presence of albumin, blood and casts in the urine, absence of appetite, with a feeling of weight and discomfort in the stomach; a furred tongue; enlarged tonsils and pharyngeal glands; there is swelling and tenderness of the parotid and submaxillary glands; teeth get loosened; gums recede and become ulcerated; saliva gets thick and viscid; fever and depression set in. If the dose is large the symptoms get aggravated and end in the falling of the teeth; ulceration and abscess of the mouth, necrosis of the jaw bones; great prostration; anæmia; emaciation; repeated hæmorrhage and death.

I would like to quote here the case of a quack who suffered from mercurial paralysis. This quack used to prepare medicines by heating mercurial salts. During the preparation of these medicines, he used to inhale the mercurial vapours. Consequently after a period of some years he had paralysis, which was successfully

* Read at the meeting of the Nuzvid Medical Practitioners' Association, held on 27th July, 1947.

Nov., 1947]

treated by sodium thiosulphate injections and oral administration of purified sulphur.

The second drug in use in the malpraxis is opium (*Ahiphena*) $\frac{1}{2}$ to 2 grains in infants and more in adults. This is given as a routine thing to many mofussil infants for the first three months. The child gets drowsy and does not cry during nights giving relief to the mother; a large number of these children coming under observation for retention of urine, faeces, abdominal distension and coma. We find pin-hole contraction of the pupils.

The third drug in order is thymol. This is given either separately or in combination with *jund*. Dose 15 to 60 grains or more in children for indigestion, fever, cough, diarrhoea, etc. In the labour classes adults use thymol for vague pains all over the body in 15 to 30 grains doses. In cases where the drug is not given in larger doses, there will be some relief of the said symptoms. In the majority of cases, somehow, patients complain of difficult micturition, scanty high coloured urine, with shooting pains in the region of the kidneys. There are a few instances of abortion when pregnant women were given this drug for some pains in the body during the early months of pregnancy; some other patients complained of vertigo after taking this drug.

Garlic (*Allium sativum*) is used not only as a drug but also as an article of food. In deep-seated inflammations such as fibrositis, neuritis, arthritis and pleuritis, its juice is applied externally as a counter-irritant. Internally, it is given in diarrhoea, dysentery, bronchitis, pulmonary tuberculosis, whooping cough and in states of unconsciousness, where the upper respiratory tract is loaded with phlegm, the drug of choice with the unschooled vaidyas is the juice of the garlic in doses of 1 to 2 or 3 oz. It is actually allowed to run into the nostrils and mouth. The properties of the raw juice are: it is a caustic rubefacient, irritating the part whichever it comes into contact with, and actually vesicles would appear; the patient vomits and purges due to gastro-intestinal irritation; the irritation is to such an extent that the patient was passing blood both in the vomit and purging. The garlic is largely used by the womenfolk during puerperium. It is used not only as a drug to act on the uterine muscle, but also as an article of food. A quantity of about 1 to 2 tolas is taken modified in a single diet. A girl (a near blood relation of the writer) was taking this garlic continuously for more than 2 to 3 weeks in very large doses, following probably the saying: 'The garlic does more good to a puerperal woman than what a mother does really to her beloved daughter'. What happened with this particular girl was that she was nursing a baby of seven or eight months. For the well-being of the child the mother was advised to observe diet. The conception of diet in the rustic sense was that the quantity of diet should be nothing but modified garlic. When she

took garlic continuously for some weeks, the baby developed petechial hæmorrhages here and there on the body. These hæmorrhagic spots developed gradually in number and intensity and one day the child was observed to be unable to take milk from the mother's breast. She was unable to swallow even water. There was paralysis first of one side of the face and then of the same side of the body. The child was fairly conscious during the early part of this paralytic stroke but in the later stages, when she got extremely weak due to lack of nourishment, coma supervened and the child died. The cause of death in this particular baby was attributed to hæmorrhage of a fairly large amount in the brain area. The important fact is this that there was wholesale hæmorrhage all over in the body and brain. Among other drugs, which have been largely used for various conditions, are the marking nut, *asafætida* and *chitramoolam* (*Plumbago zeylanica*). Every drug when properly applied has its therapeutic value; but when the therapeutic dose is exceeded, it acts as a poison and brings trouble.

One more interesting instance of the ignorance of the uneducated masses is the following: 'During the anxious period of illness the doctor is invited respectfully and treated in the best manner possible. Everything of the patient is almost offered if he takes proper care of the patient and treats him. After finishing the job with the doctor, the party give a warning to the medicine-man that there is a dog which has delivered pups in their house and advise him not to visit frequently for fear of being bitten by the dog. He is scolded for the red pills which have caused the patient hiccough and also for the black pills which have caused vomiting. The party wishes that the medicines were buried in earth and challenges the ability of the doctor. "After all the patient," it is said, "got well after prayers to the family deities (*potharazu* and *polaramma*) and the offer of a goat and a saree for each. All right, then, what is it you want for your remuneration; you can have a measure of grain".'

The Indian Medical Gazette

Fifty Years Ago

CAN TYPHOID FEVER BE ABORTED?

THE reply in the affirmative to this question has raised a somewhat acrimonious and unnecessary wordy war among medical men in the United States. We are not usually taught that this disease can be cut short; in fact, our chief reliance is upon maintaining the patient's strength and upon good nursing. An American physician, however, with characteristic boldness, has replied with no uncertain sound that by his method of treatment this disease can surely be aborted and robbed of its chief terrors. From

time to time cases of typhoid fever, which had been cut short in the second or third week, have been reported, and it has not always been possible to beg the question by assuming an incorrect diagnosis. It would, however, be very difficult to make such an easy assumption in view of the long list of cases recorded by Dr. J. E. Woodbridge of Cleveland, Ohio, at the late meeting of the American Association; nor is it possible to assume that the 193 physicians, whose cases are quoted and tabulated by Dr. Woodbridge, are deliberately making false statements, therefore we are bound to pay attention to their truly remarkable results. It appears that some years ago Dr. Woodbridge introduced a new method of intestinal antiseptics for the treatment of typhoid fever, and we have now before us the detailed results of an extensive trial. We have not been able to accurately find out the exact formula, nor do we know the composition of the antiseptic tablets used. We gather, however, that they contain guaiacol, thymol, and formaldehyde. The method appears to be at once eliminative and antiseptic.

Within recent years we have heard much of the antiseptic treatment of typhoid fever. There is scarcely a known antiseptic agent which has not been tried, from corrosive sublimate to betanaphthol, each in its turn earning a short-lived reputation only to end in disappointment. Why the particular combination suggested by the American physician should be so successful we are unable to say, but that it is so clear when we read of 7,827 cases with a death-rate of only 1.9 per cent (*under two per cent*). Moreover, the average duration of illness in 4,935 cases was only 12 days. Truly this is abortive treatment *par excellence*. Of the cases which recovered 101 had intestinal hæmorrhage, and 95 relapses are recorded. According to our author 'the severity of the disease is greatly ameliorated, the symptoms minified (*sic*), all grave complications averted and dangerous sequelæ prevented'. 'The tongue', he goes on to say, 'is quickly rendered moist, tympanites quickly relieved, the excrements (*sic*) lose their offensive odour, delirium is rare, and the "typhoid state" unknown'. With such a record well may Dr. Woodbridge exclaim that 'these results have never before been obtained, in hospital or private practice, in so large a number of cases and by so many physicians'. To anticipate the obvious criticism* that the American type of the disease is a mild one or has changed, Dr. Woodbridge quotes some recent statistics of the disease in several large hospitals in the States, which show that in the closing years of the century typhoid fever has lost none of the virulence that distinguished it forty years ago. To emphasize the

extraordinary nature of his results he quotes the death-rate within the past ten years of several well-known hospitals, *e.g.* St. Bartholomew's 10 per cent, Boston Hospital 13 per cent, St. Louis' City Hospital 20 per cent, while Murchison placed it at 17.4. The most favourable death-rate we have before heard of is that of Brisbane Hospital where the strict cold-bath treatment gave a mortality of only 7 per cent. All of these compare badly with Dr. Woodbridge's 'under two per cent'.

To us in India, where enteric fever is an ever-present evil, it will be very satisfactory should these remarkable results be confirmed and repeated by physicians here and in other countries. This method of treatment is sure to be tried, and we shall be glad to receive reports about it; for the present we suppress a natural scepticism and only allow ourselves to say it is almost 'too good to be true'.

THE SCIENTIFIC STUDY OF PREVENTIVE MEDICINE IN INDIA

To the indomitable energy and genius of a single man, who had neither influence nor large means, modern biologists owe the establishment of the magnificent Zoological Station at Naples, an institution which has become world famous amongst the scientific men of all nations.

It is not much more than thirty years ago that naturalists were wont to study marine fauna as dried or preserved specimens stored in museums, in which state they bore but a remote resemblance to the living animals. Small wonder is it that classification was in a chaotic condition, and that so little was known about the development and organs of a large portion of the Invertebrate Kingdom.

In 1870, a private *docent* of Jena, Dr. Anton Dohrn, was inspired with the original idea of founding a marine station for biological studies, an institution wherein the fauna of the sea could be observed in their free-swimming condition. Instinctively he chose one of the most beautiful spots on earth on the shores of the Mediterranean. After encountering almost insuperable difficulties, after meeting with many rebuffs from the Italian and German governments, after spending the whole of his fortune, he finally triumphed at the end of five years' struggle and succeeded in establishing, on a secure basis, an international temple of science. It is one of the sights of Naples, and it combines laboratories, aquaria, and such accessories of a marine station as steamers and fishing boats for dredging and trawling purposes. Here students of all nationalities are assembled, and many of the European States contribute to the maintenance of the institution, receiving in exchange the right to keep one or more investigators at the laboratory. The German government alone pays £4,000 per annum.

If Dohrn could effect such a result in a subject like zoology, and if another enthusiastic

* The accuracy of the diagnosis in the reported cases has been challenged, but we may note that the cases treated by this method in the Bellevue Hospital, New York, answered to the serum reaction test of the Eberth bacillus.

THE USES OF VITAMIN E

While the main use of vitamin E up to the present has been the treatment of cases of habitual abortion and sterility of dietary origin (with success in about 70% of cases when whole oil—as in Fertitol—was given) wheat germ oil is being increasingly used for cases of primary muscular dystrophy, amyotrophic lateral sclerosis, anterior poliomyelitis and in rarer cases such as amyotonia congenita.

There are some indications that other factors in Bemax, probably part of the B complex, render the action of vitamin E more effective and it may, therefore, be desirable to reinforce the action of Fertitol in this way.

FERTITOL

Wheat Germ Oil Capsules

A highly active natural and stable source of vitamin E. Each 5 minim capsule is standardized to contain 3 mg. α -tocopherol.

Further particulars concerning Fertitol and Complevite from Martin & Harris Ltd., Mercantile Building, Lall Bazar, Calcutta. Products of Vitamins Limited, London, England.

Complevite

COMPLETE

in the most important vitamins and minerals

BALANCED

to meet known deficiencies in the average diet

CONVENIENT

dosage, in tablet form

ECONOMICAL

— a single supplement for manifold deficiencies

The graph below shows the multiple nature of Complevite tablets and also demonstrates the extent to which Complevite ensures optimal nutrition.

*The iron in Complevite exceeds the calculated deficiency expressly to combat the nutritional anaemia so common in children and in women of child-bearing age.

SEVERE BURN

(Area 162 sq. inches)

A treatment using tulle gras, pressure dressings and plaster fixation

Fig. 1

Fig. 2

CASE HISTORY—The patient, a young man, was admitted to hospital, having been burnt by an electric blanket. The raw area measured 162 square inches. Excision of the burnt area was performed on the same day. Tulle gras (Jelonet) was applied. Fixation by Gypsona plaster of Paris bandages applied over the whole area, abdomen and thigh. The patient was given a blood transfusion. Seven days later, the affected part was covered with thin razor grafts from both thighs and a pressure dressing of Elastocrepe applied. Fixation was again secured with Gypsona plaster of Paris. The patient was discharged to duty 7 weeks later.

The details and illustrations above are of an actual case. T. J. Smith and Nephew Ltd., Hull, England, manufacturers of Elastoplast, Elastocrepe and Jelonet, are privileged to publish this typical instance of the use of their products with success in the belief that such records will be of interest.

Fig. 3

TRANQUILLITY

A calm outlook and freedom from worry and nervous tension are rare in these days. The intense application to war work and consequent mental and physical strain are revealed in widespread headaches and insomnia.

Veganin may well be used to soothe the overwrought nerves, relieve pain and induce sleep. It is a synergistic combination of acetylsalicylic acid, phenacetin and codeine, and is widely known as a dependable and highly effective analgesic, sedative and antipyretic. Veganin is neither toxic nor habit forming.

scientific genius was able to inaugurate the *Institut Pasteur* to deal with bacteriology and antitoxins, surely it were possible for a great and powerful government, like that of India, to found an Imperial Institute for Preventive Medicine on sound and comprehensive principles.

To clear the way, in case of any misapprehension, let us first consider what preventive medicine is *not*. It is not merely a matter of conservancy, sanitation and vaccination, though unfortunately that is a commonly accepted definition of it current in India. Neither is it wholly and solely a matter of bacteriology, or of antitoxins and serum-therapy. It is not simply a combination of chemistry and hygiene or of chemistry and bacteriology, though one might be led to infer that such is the case if we were to judge from the nature and designations of certain appointments in India.

The subject of preventive medicine has a far wider scope, and includes every subject that conduces to the health and comfort of civilized communities. It is concerned with chemistry and physics, with physiology, pathology and bacteriology, with hygiene in its narrow sense of water-supply, drainage and ventilation, with food and dietaries, clothing and buildings, trades and occupations, with epidemiology and medicine, not to mention also meteorology, climatology and geology, and in fact, everything that bears directly or indirectly on the preservation of health and the prevention of disease amongst mankind. But the attention and energy of investigators should not be confined only to problems bearing on the aetiology and spread of disease. One of the main objects of such a Central Institute should be to conduct observations and experiments along practical lines, tending towards economy in imperial, provincial and local expenditure. Knowledge is power, and in no subject is that proverb more true than in its application to the health and prosperity of a nation.

C'est le premier pas qui coute, and this should be kept in mind in the initiation of a Central or Imperial Institute for research. Each of the presidency cities should have its laboratories for teaching purposes—chemical, physiological, pathological and bacteriological, also laboratories for provincial and municipal work—hygienic, medico-legal, exercise, etc. But over and above, and quite separate from this, the Imperial or Central Institute should deal with the larger and more intricate problems that cannot be solved by merely applying to India the results obtained by observers in Europe. Each province should contribute an annual sum, raised by the Local Government and by means of private donations, towards the maintenance of this Central Institute. In exchange each province should be allowed to send one or more medical officers, specially qualified to work at particular subjects, under the guidance and direction of a permanent director and his assistant.

The question of expense, and how to meet it, is an all-important one in these hard times. In all probabilities this could be overcome by Local Governments transferring certain second class stations, now held by members of the Indian Medical Service, to the uncovenanted branch of the Civil Medical Department, and to senior Civil or Military Assistant Surgeons. Such a procedure would be in accordance with the avowed principle of attempting to improve the prospects in these services, and at the same time the pay saved by the change would go towards the maintenance of the I.M.S. officers who would be transferred to special duty at the institute, such transfers not involving any material increase in the *cadre* of this service.

Current Topics, Etc.

Reactions to a Bismuth Compound

By R. N. BARNETT

(Abstracted from the *Journal of the American Medical Association*, 6th September, 1947, Vol. 135, p. 28)

A GIRL, aged 27 months, had an uneventful adenoidectomy. Two weeks later she received four of the children's size suppositories for control of gingivitis. In four days coma and convulsions developed, and death followed within seventy-two hours. At autopsy, cerebral oedema, a swollen fatty liver and an acute duodenal ulcer were present.

An asthmatic boy, aged 6 years, received one suppository containing the bismuth salt each day for three weeks. No suppositories were given for four days, but he then received four suppositories in forty-eight hours for a pharyngitis. On the fifth day the pharyngitis had subsided, food was withheld and a tonsillectomy performed with the patient under ether anaesthesia. Coma supervened within twenty-four hours, and death followed within thirty-six hours. At autopsy, there was cerebral oedema and a fatty liver. The fasting state plus anaesthesia provided an ideal substrate for the action of any hepatotoxin.

A boy, 2 years of age, was given two 'analbis' suppositories for otitis media and pharyngitis. About eighteen hours after the second suppository he went into severe collapse, followed the next day by fever and lethargy. He recovered after supportive measures and BAL therapy. The total dosage of BAL per kilogram of body weight is one of the largest ever given. This drug was administered at the suggestion of Dr. W. T. Salter, professor of pharmacology at the Yale University School of Medicine, in the belief that the unknown toxic agent might be a heavy metal. Whether its use was of any value is a matter of conjecture.

A girl, aged 2½ years, had been well until 18th December, 1946, when there developed a cough, an elevation of temperature to 102°F., and an apparent infection of the upper part of the respiratory tract. She vomited twice. On examination, she was moderately dehydrated; the pharynx was red and swollen; the liver was not palpable. She was given rectal fluids, acetylsalicylic acid and three suppositories containing the bismuth salt of diallylacetic acid in the course of about twenty-four hours. By 20th December, she appeared well. At 3 a.m., 21st December, she awoke suddenly and vomited. Later that day she was admitted to Babies Hospital because of drowsiness. She was semi-comatose on admission; the abdomen was rounded and soft, the liver large and somewhat tender. She was treated with clyses and a transfusion, but on 22nd December she became cyanotic, with slow Cheyne-Stokes respirations, and died.

The chief post-mortem observations were a large liver weighing 720 gm., which was mottled bright red and yellow, mild ascites (100 c.c.) and œdema of the peritoneal fat and connective tissue, decided œdema of the gastric mucosa and extreme cerebral œdema. There was no icterus. On microscopic examination, the liver showed acute early necrosis and the renal tubules contained much fat. There was a mild interstitial pneumonia, and examination of other organs revealed little that was unusual. There was no excess of bismuth in the liver.

Suppositories bearing the same lot number as those given to patients 1, 2 and 3 were analysed. The bismuth content was less than that declared (0.0150 gm. against 0.0225 gm.). No heavy metals other than bismuth were found. The only substance found besides bismuth was a fatty acid in quantities too small for analysis. This is presumably what is identified in the literature supplied by the company as heptadienecarboxylic acid. More accurately this is said to be diallylacetic acid.

This is closely related to several allyl compounds of known high toxicity, as allyl amine and allyl alcohol and allyl formate, which is hepatotoxic in rats.

It is not believed that bismuth is the agent responsible for the toxic action of these suppositories for several reasons. It was present in only small amounts in the organs on which analyses were performed. There were no inclusion bodies in the renal tubular epithelium, nor was there any evident nephritis. Finally, there is no convincing evidence that bismuth has ever caused hepatic damage of the type here described.

The assumption that the heptadienecarboxylic acid or a contaminant thereof may be a hitherto undescribed hepatotoxin seems plausible.

Four cases are described with autopsy observation in 3 of which profound collapse, fever, central nervous system symptoms and in 3 cases death followed the administration of 'analbis' suppositories containing the bismuth salt of hepta-

dienecarboxylic acid (diallylacetic acid) for the treatment of infections of the upper part of the respiratory tract in children.

The Eligibility of Syphilitic Persons for Life Insurance

By J. E. MOORE

and

I. L. SCHAMBERG

(Abstracted from the *Journal of the American Medical Association*, 30th August, 1947, Vol. 134, p. 1532)

THREE alternative policies as to syphilis in applicants would appear to be open:—

1. To disregard altogether the factor of syphilis, on the grounds that (a) less than 10 per cent of applicants (percentage varying on the basis of race, sex, age, socio-economic status and geographic location) are infected at the time of application, (b) in those who show clinical or laboratory evidence of the disease at the time of application, or who admit a history of infection or of treatment for it, the overall increased mortality hazard may be disregarded, since (c) in those without clinical or laboratory evidence of infection, or who deny its previous existence, a substantial number are nevertheless already actually infected but are medically unrecognized as having the disease; some are deliberately concealing the fact or will become infected after insurance is granted, thereby increasing the hazard in the supposed non-syphilitic group to a point approaching that in the syphilitic group.

2. To require, as at present, the routine questioning of all applicants as to the existence of syphilis and in addition to insist on a routine blood serologic test for syphilis of all applicants.

3. To continue, as at present, to decide individually the question of insurability of all persons in whom syphilis is recognized by clinical or laboratory evidence or by history and to ignore the factor of syphilis in all others, with full knowledge that the latter group will nevertheless contain a substantial proportion of infected persons.

Each of these alternatives is open to several objections. The first would unquestionably impose a slight but definite increase in the overall actuarial risk, by the inclusion of persons with definitely or probably fatal forms of the disease.

The second, requiring routine serologic testing of all applicants, would add materially to the cost of examination and, especially in the case of the Veterans Administration, would impose the difficult, and in some cases nearly impossible, task of differentiating biologic false positive serologic tests from those actually due to syphilis.

Because of these objections to the first two alternatives, the third (in spite of its obvious medical and actuarial drawbacks and the

premium which it places on concealment of disease on the part of applicants) will probably continue in force.

Whether either the second or third alternative is chosen—whether a deliberate search for syphilis is made by means of routine serologic testing of all applicants or whether the problem is dealt with largely by chance, as at present—what shall be done with the applicant in whom syphilis is detected?

Here certain principles appear clear:—

1. No applicant with untreated syphilis in any stage should be granted insurance if, as with commercial companies, the applicant must demonstrate good health.

2. If treatment has been given, it should have been adequate. In this connection, the term adequate is used to describe the amount and character of treatment which is sufficient to cure the majority of patients in a particular phase of syphilitic infection. It is recognized that many individual patients may have been cured with less than this average amount, while others may not have achieved cure with much more. If an applicant has received less than the average adequate amount, and even though he may appear cured as a result thereof, he should be required to complete the average amount of treatment before insurance will be granted. The standard of adequacy is a constantly changing one, and too rigid requirements should not be laid down.

3. In certain phases of syphilitic infection, though not in all, a period of observation following treatment should be required, in order to demonstrate the probability of cure.

4. In all patients with syphilis the cerebrospinal fluid, tested in a reliable laboratory, should have been shown to be within normal limits as to cell count, quantitative protein determination, complement-fixation test and colloidal test, these tests having been made two years or more after infection.

5. The physical status should be normal, without clinical evidence of cardiovascular syphilis or neurosyphilis. Scars of healed gummatous lesions or stigmas of congenital syphilis should not, however, preclude insurance.

Prevention of Reaction to BAL

By M. TYE.

and

J. M. SIEGEL

(Abstracted from the *Journal of the American Medical Association*, 23rd August, 1947, Vol. 134, p. 1477)

IN the treatment of poisoning due to heavy metal with BAL (dimercaprol, or 2, 3-dimercaptopropanol) undesirable side-effects have been previously noted. These reactions consist chiefly of some of the following symptoms: nausea, vomiting, headache, burning sensation

of gums, nose and eyes, profuse lacrimation and salivation, abdominal cramps, flushing of face, tingling of extremities, burning of skin, feeling of constriction of the chest and restlessness. At times these complaints are so severe as to necessitate discontinuance of treatment.

In view of the close resemblance of the severe symptoms to those seen in cases of serum sensitivity reactions 0.6 c.c. of a 1:1,000 solution of epinephrine hydrochloride was given intramuscularly. He obtained rapid and complete relief.

Influenced by this response the writers gave the patient 25 mg. of ephedrine sulphate by mouth one-half hour before the next injections of BAL in an attempt to prevent a recurrence of the reaction. None of the toxic symptoms were noted after any of the ten subsequent injections of graded doses of 2 to 4.5 c.c. of a 10 per cent solution of BAL preceded by an oral dose of ephedrine sulphate.

A second case reaffirmed the foregoing observation. A Negro with a generalized dermatitis due to a heavy metal was started on BAL therapy after being prepared with ephedrine sulphate, 25 mg., given orally a half-hour before each injection. No toxic symptoms were noted. After the sixth injection (dose 4.5 c.c.) had been given the 25 mg. ephedrine sulphate was omitted prior to the seventh dose. Within a few minutes the patient noted severe lacrimation, headache, a feeling of constriction in the chest and a burning sensation of the skin of the trunk. The following injections of BAL were preceded by 50 mg. of ephedrine sulphate a half-hour before their administration, and none of the previous unpleasant symptoms were experienced.

Preparation of the patient with ephedrine sulphate shortly before the injection of BAL may lessen the intensity or prevent entirely the side-effects of this valuable remedy.

Reiter's Syndrome

(Abstracted from the *British Medical Journal*, 12th April, 1947, Vol. I, p. 495)

THE syndrome consisting of polyarthritis, urethritis, and conjunctivitis, originally described by Reiter in 1916, is perhaps not yet entitled to be known as Reiter's disease, since its aetiology remains obscure and it is consequently not known to be a single entity. Several correspondents have discussed its possible relationship to bacillary dysentery. The association between these two conditions seems to be far from constant and the evidence as a whole does not support the belief that Reiter's syndrome has any consistent connection with intestinal disease. The resemblance to gonorrhoea is striking only in the distribution of the lesions; all tests for gonococcal infection give negative results, and neither sulphonamides nor penicillin are curative. The disease runs a long febrile course, its

different manifestations often appearing successively and the arthritis migrating from one joint to another. It is apparently confined to young adult males and is not considered to be venereal in origin. No explanation of the age and sex distribution can be offered.

In the absence of any demonstrable causative bacterium it has been supposed that the disease is due to a virus and inclusion bodies have been demonstrated in material from the urethra and conjunctiva. Also incriminated are the so-called 'pleuropneumonia-like' organisms, which have so long been denied the dignity of proper nomenclature. Although responsible for two specific animal diseases—bovine pleuropneumonia and contagious agalactia of sheep—these organisms have not been fully identified as the cause of any human disease, though they exist in the human body. Their extreme pleomorphism and the special techniques required for their study are obstacles to ready recognition, and perhaps much remains to be discovered about their activities in relation to human pathology. Another line of argument is therapeutic: pleuropneumonia-like organisms are sensitive to gold salts, and patients were accordingly treated with myocrisin. This appears to have had a very satisfactory effect, the lesions resolving and the sedimentation rate falling steadily. This is no proof of a particular aetiology, since many drugs are active against more than one type of micro-organism. On the other hand, it is the result to be expected in accordance with the hypothesis, and in the interests both of further investigation and of successful therapy the effect of gold should certainly be observed in future cases.

Treatment of Early Syphilis with Penicillin

By T. H. STERNBERG

and

W. LEIFER

(Abstracted from the *Journal of the American Medical Association*, 4th January, 1947, Vol. 133, p. 1)

An analysis has been made by the authors of the army records of 1,400 men with early syphilis treated with 2,400,000 units of penicillin in aqueous solution or isotonic solution of sodium chloride prior to 1st February, 1945.

There were no severe toxic reactions, and all patients completed the prescribed schedule of treatment.

Approximately 84 per cent of the patients were observed for over nine months following treatment.

Satisfactory progress was obtained in 94.3 per cent of 600 cases of sero-negative primary syphilis, in 89.9 per cent of 564 cases of sero-positive primary syphilis and in 83.0 per cent of 236 cases of secondary syphilis.

The cerebrospinal fluid was examined following treatment in 719 patients; it was normal in 714 and abnormal in 5 (0.69 per cent).

The high overall satisfactory progress rate of 90.6 per cent, admittedly tentative because of inadequate follow-up, was attributed to the considerable proportion of cases of the disease in the primary stage (83.1 per cent) and to the fact that the patients were probably treated with penicillins of satisfactory potency.

The rate of failure was approximately 5 per cent in the 790 white patients and 15 per cent in the 610 Negro patients, and the implications of this disparity in respect to reinfection were discussed.

Penicillin in the Treatment of Neuro-syphilis

By A. S. ROSE

and

H. C. SOLOMON

(Abstracted from the *Journal of the American Medical Association*, 4th January, 1947, Vol. 133, p. 5)

Two hundred and thirty-six patients with neuro-syphilis were treated with penicillin between 1st February, 1944 and 1st April, 1946. Of these, 210 are now being followed. The clinical results in the first 100 cases followed one year or more are presented. The results of examination of the spinal fluid of all patients on whom an examination was obtained at least three months after treatment, as well as the 100 cases followed a year, are tabulated.

Clinical results

The evaluation of clinical results of treatment in a disease so complex as late symptomatic neuro-syphilis is extremely difficult. Psychiatric symptoms may be affected, as in the non-syphilitic patient, by changes in the environment, by alterations in the general physical status or by the administration of active treatment. Furthermore, patients may show improvement in some symptoms and progression in others. New symptoms such as convulsions may appear while all other symptoms improve. To obviate as many of these difficulties as possible, the writers present the clinical results only in cases followed at least one year, and we classify the status of the patients as 'improved', 'no change' and 'worse'.

The majority of patients were given a short course of fever therapy in combination with penicillin. The fever therapy consists of four to six paroxysms of malarial fever with temperatures above 104°F. or a total of twenty hours of temperature above 105°F. No other antisiphilitic treatment was given. If more treatment was needed, administration of penicillin was repeated.

Twelve of the patients with dementia paralytica were treated with penicillin alone. Nine

(75 per cent) of these 12 patients required retreatment with penicillin. The small number of patients in this group makes it impossible to draw any conclusion other than that 3,000,000 units of penicillin is insufficient treatment for dementia paralytica.

Each patient was given 3,000,000 units of penicillin intramuscularly as a course of treatment. Intervals of injection and the number of units per injection were varied according to plan.

Clinical results of the 100 patients followed one year or more show 62 improved, 35 with no change and 3 worse. Thirty-eight patients were retreated with penicillin.

Following treatment the cell count and total protein contents of the spinal fluid return toward normal in from three to six months and six to nine months respectively. The strength of the Wassermann titre decreases more slowly. Of the 100 patients followed a year or more, 11 have a negative Wassermann reaction.

In one patient dying of dementia paralytica it was felt that penicillin given during an acute, extremely overactive psychosis may have contributed to the death. At least no quietening effect was obtained, and it is possible that penicillin intensified the symptoms. In no other case did it appear that treatment contributed to the fatal outcome.

Because the majority of patients in this study received a short course of fever therapy as well as penicillin, the question is raised as to whether the changes observed are due to fever therapy. A survey of results of examination of spinal fluid in the 19 patients treated with penicillin alone reveals similar and comparable changes to the larger group, although the shift in the titration of Wassermann reactions was less striking. This, together with published data from other clinics, demonstrates that penicillin alone will effect a change in the spinal fluid. Since the amount of fever therapy administered to these patients is considerably below that which experience has proved necessary for the best treatment of this disease, we believe that the results to be obtained at the end of several years will give evidence of the usefulness of penicillin.

The need for retreatment in a little more than one-third of the cases followed one year or more indicates that 3,000,000 units of penicillin combined with a short course of fever therapy is not optimum treatment for late symptomatic neuro-syphilis.

Early Congenital Syphilis

By R. V. PLATOU *et al.*

(Abstracted from the *Journal of the American Medical Association*, 4th January, 1947, Vol. 133, p. 10)

AMONG 252 infants with congenital syphilis, a single course of penicillin administered over a period of seven and one-half to fifteen days has yielded satisfactory results in 73 per cent,

unsatisfactory in 9.1 per cent, and in 17.9 per cent results are still classed as uncertain. Empirically judged severity of syphilis or cerebrospinal abnormalities had little prognostic meaning; the latter improved remarkably after treatment. Dosage schedules employing more than 40,000 units of the drug per kilogram of body weight yielded better results than those employing lesser amounts. There is some evidence to suggest that larger dosage schedules administered over a longer period of time may be more effective. Dramatic clearing of active manifestations of infection during or soon after treatment is the rule. Clinical relapses have been infrequent, with only 6 encountered at intervals of three to eleven months after treatment. As time passes, the number of cases with unsatisfactory or uncertain results diminishes, while there is a proportionate increase in that of symptomatic and serologic cures.

Changes to seronegativity are not unusual a year or more after the completion of treatment, though most babies become seronegative between the fourth and twelfth months following therapy.

Judged by outcome, all planned treatment schedules employing sodium penicillin alone have been remarkably effective. Their efficacy, rapidity and safety in this 'exquisitely chronic' disease have amply demonstrated that this drug is the best single agent yet employed for the treatment of congenital syphilis.

Penicillin therapy has not altered the familiar contention that treatment of the baby is far more important than treatment of its syphilis. Hazards inherent in socio-economic environments responsible for a high incidence of this disease undoubtedly account for the high fatality rates seen under any form of treatment. Although syphilis or its direct sequelae must be regarded as potent contributory factors, deaths are almost always adequately explainable on non-syphilitic bases.

Until the true make-up of commercial penicillin has been clarified or until crystalline fractions are evaluated, the writers offer the following broad suggestions for therapy:

1. Young syphilitic infants should receive a total dosage of at least 100,000 units per kilogram of body weight.

2. This amount should be divided into approximately one hundred and twenty equal intramuscular injections given over a period of twelve to fifteen days.

3. These injections should be given at intervals of no longer than three hours around the clock.

Serological Tests for Syphilis

(Abstracted from a letter from A. C. T. Vaughan published in the *Lancet*, no. XXIV of Vol. I, 1947, p. 923)

In their interesting recent paper in *Lancet*, 3rd May, 1947, p. 588, on the Results of Parallel Kahn and Wassermann Tests in Relation to

Penicillin Therapy of Syphilis, J. F. Heggie and his colleagues demonstrated, in those patients whose serological state was examined at short intervals, that the Wassermann reaction reverted to negative before the Kahn.

A possible reason for this 'disproportionate rate of reversal' is that the conditions of the standard Harrison-Wyler-Wassermann which they used do not permit the detection of small amounts of syphilitic 'antibody'. Both complement-fixation and precipitation tests for syphilis are based on the same fundamental principle—the specific combination of the lipoidal haptené ('antigen') with syphilitic 'antibody'. In the former use is made of the well-known property, particularly marked during the early stages of formation, of specific aggregates to fix complement; while in the latter the conditions of the reaction are so adjusted that aggregation proceeds to visible precipitation.

Complement is fixed most avidly in the zone of slight antibody excess; so, in order to obtain maximal sensitivity from the Wassermann reaction when examining sera of low reactivity (e.g. patients near the completion of their treatment), it is necessary, among other things, to use a more dilute 'antigen' than that used in the standard Wassermann. This is essentially the basis of Richardson's modification of the Harrison-Wyler technique, which the writer has found to be most satisfactory in that, among other advantages, the increased sensitivity is not obtained at the price of specificity.

Some results from treated syphilitics whose sera were examined by the Richardson modified test as well as by the standard Wassermann and standard Kahn are set out in tables I and II.

It is evident from table I that the modified test is much more sensitive than the standard Wassermann, being in fact comparable to the standard Kahn.

From table II it may be seen that not only is there an increase in the number of reactive sera detected when the modified Wassermann test is used but also in the number of agreements with the Kahn test. Further, in the cases treated with arsenic and bismuth, the number of sera which gave a positive Kahn reaction but a negative modified Wassermann was balanced by a similar number in which the reverse held. (The results from the smaller number of meprobamate-treated cases show a similar trend.)

The reasons for these divergences are not always clear but may include the following:—

1. Slight day-by-day variation in the sensitivity of the tests are inevitable in a complex biological reaction, such as the Wassermann, when carried out under routine conditions, and differences in the fixability of different samples of complement are a potent cause of such variation.

2. Subjective errors which are due to the difficulty of maintaining over a period of time a constant assessment of the strength of minimal reactions (both the Kahn and the Wassermann

show a more or less continuous change in intensity from positive to negative).

3. Neither test is strictly quantitative.

It would, therefore, appear an advantage to carry out a sensitive complement-fixation test in addition to a satisfactory precipitation technique such as the standard Kahn, not only for their differing intrinsic ranges of sensitivity but also to compensate for any possible daily variation.

Behcet's Syndrome

(Abstracted from a letter from Nikos Lorandos published in the *British Medical Journal*, 21st June, 1947, p. 901)

THE writer (Nikos Lorandos of Athens) expresses his views of Dr. E. W. Prosser Thomas's article on Behcet's syndrome as well as on thrombophlebitis. In the *Proceedings of the Medical Society of Athens* (1930, p. 586) Dr. B. Adamantiades presented the first known case of recurrent iritis with hypopyon, insisting at the same time on the small ulcerations of the mouth and genitalia. All these three elements were characterized by recurrences, appearing either at the same time or at independent periods. Later (*Annales d'Oculistique*, 1931, 168, 271) followed the same description of this syndrome in French. In 1931, Dr. Daskalopoulos (*Proceedings of the Greek Medical Society*, Athens, p. 717) describes a record case. There follows the description of Whitwell (1934), and later again in 1937 Behcet, of Constantinople, describes the syndrome in the *Dermatologische Wochenschrift* (105, 1152), in German.

The same author (Dr. Adamantiades), in a careful study of two other cases which came under his notice, found that a fourth element is quite common and describes in detail the thrombophlebitis either of the central vein of the retina or of the legs (Greek Ophthalmic Society, 7th June, 1945, and *Annales d'Oculistique*, 1946, 179, 143). This element was also observed by Urbanek, J. (*Zt. f. Augenh.*, 1929, 69, 174), Blobner, F. (*Zt. f. Augenh.*, 1937, 91, 129), Delord, E. (*Annales d'Oculistique*, 1941; 177, 366), and Tebeyan and Kalfayan (*Annales d'Oculistique*, 1945, 178, 335), either on the legs or in the retina. The writer is pleased to see that this thrombophlebitis was also observed by Dr. Prosser Thomas.

Dr. Adamantiades describes this syndrome as the complex syndrome of recurrent iritis with hypopyon, which according to the rules of nomenclature is the name and term accepted by Greek medical literature. The writer adds that this syndrome is comparable to the disease known as 'periodic ophthalmia (moon-blindness) of horses' according to the same author. The writer also wants to add that Dr. Thomas's contribution to the subject is much welcomed in Greek medical circles in Athens.

Stevens-Johnson Syndrome affecting Genitals:**A Case Report**

By D. R. LAURENCE

(Abstracted from the *Lancet*, 21st June, 1947, Vol. I, p. 888)

A SOLDIER, aged 21, was admitted on 28th March, 1947, complaining of sore throat and cough with watery sputum for 6 days. For a month he had had a mild dry eczematous dermatitis of both forearms, but during the previous 2 to 3 days a different rash had developed, consisting in small circular scaly erythematous patches which coalesced in places. These were numerous on the forearms and there were a few on the trunk. On the day after admission a severe stomatitis, conjunctivitis, and halanitis developed. The mouth was covered with a peeling greyish membrane, and the pharynx was red and injected. Three swabs from the mouth showed no Vincent's organisms, and from the throat *Streptococcus viridans* was grown. The conjunctivitis was very severe; swabs showed numerous pus cells, but no organisms were isolated. The glans penis was red, and the skin was weeping and peeling. A white blood-cell count at this stage showed 19,500 leucocytes of which 90 per cent were polymorphs, 8 per cent lymphocytes, and 2 per cent monocytes. Sputum examination showed numerous pus cells, and no one organism was predominant on culture.

The patient was very ill and toxic. He could only swallow fluids, and even this was difficult. On examination of the chest moist râles were heard all over both sides. The temperature was swinging between 101°F. and 103°F. On the second day the skin lesions became bullous with purplish edges, and a diagnosis of erythema multiforme was made. The temperature subsided almost to normal by the 7th day, although the mouth and eyes were still severely affected. The bronchitis was still severe, a pint of frothy mucopurulent sputum being produced each day. The skin lesions had increased in number and were chiefly on the back and arms. The lips were grossly swollen and cracked, and the patient could hardly speak.

By the 26th day he was almost well. The conjunctivitis was improving and all that remained of the skin lesions were brown pigmented patches. A stricture of the foreskin had developed as a result of the inflammation.

Swabs taken from the bullous skin lesions gave no organisms on culture; nor did swabs from the penis. It was not possible to decide whether there was a pure urethritis owing to the severe inflammation and swelling of the glans prepuce.

The patient recovered and when last seen six weeks after discharge from hospital he was well, except for the occurrence for the first time of psoriasis on his arms and trunk. The pigmentation of the skin remained. Penicillin was

administered during the early stages of the disease, but did not seem to influence its course.

**Frequency of Syphilis and Some of its
Clinical Aspects in a General
Hospital Service in Algiers**

By F. G. MARILL

(From the *Bulletin de la Societe de Pathologie Exotique*, Vol. 39, p. 178, as abstracted in the *Bulletin of Hygiene*, January 1947, Vol. 22, p. 28)

THIS author draws attention to the fact that little is known about the incidence of syphilis in Algeria; he therefore analysed case records of 1,836 general hospital admissions over the period from 1919 to 1937 and gives the results of 1,297; of these 750 were Europeans, 62 Jews, and 485 natives, the respective numbers proved to have syphilis being: Europeans 155 (20.66 per cent), Jews 11 (17.75 per cent), and natives 120 (24.74 per cent); in addition 84 Europeans, 8 Jews and 99 natives suffering from other diseases had positive serum reactions.

As regards neurosyphilis, there were 40 cases (22 of G. P. I.) among Europeans, that is one in 187 of all cases and one in six of those with syphilis, and among natives 21 cases (7 of G. P. I.), that is one in 23 of all cases and one in 10 of those with syphilis.

There were 18 cases of aortitis or aneurysm among Europeans and 9 among natives; 3 of gumma in Europeans and 14 in natives; and 3 of bone lesions in Europeans and 15 in natives.

In a discussion which followed, Montel (from Saigon) pointed out that the foregoing confirmed his belief that syphilis is the same disease everywhere and the parenchymatous neurosyphilis is far commoner in coloured races than has hitherto been supposed.

**The Treatment of Gonorrhœa with
Streptomycin**
By B. D. CHINN *et al.*(From the *American Journal of Syphilis, Gonorrhœa and Venereal Diseases*, May, 1947, Vol. 31, p. 268, as abstracted in the *International Medical Digest*, August, 1947, Vol. 51, p. 99)

'If therapeutic resistance to penicillin should develop in gonorrhœa, as occurred in the case of the sulphonamides, it would be encouraging to know in advance of the availability of another drug for treatment. Accordingly, as a preliminary study, four men with acute gonorrhœal urethritis, confirmed by smear and culture, were each given 0.1 gm. of streptomycin sulfate dissolved in 3 c.c. of physiologic salt solution at hourly intervals for 5 doses. All were observed daily for three days' post-treatment and at the

seventh and tenth days. . . . Three consecutive negative cultures within 10 days after therapy and the absence of or marked improvement in clinical findings were considered evidence of cure'.

'All four cases responded promptly within 24 to 48 hours by a reduction or cessation of the urethral discharge. Cultures, following prostatic massage, were made at each examination and in all instances were found to be negative.'

'A larger series of cases was then treated in order to determine the optimum dosage. Treatment with a single dose of 0.5 gm. of streptomycin was first attempted and it was found that consistent cures could be obtained in this way'. Treatment was instituted with 0.5 gm. and lesser amounts of streptomycin in water solution as a single injection into the gluteal muscle.

All cases treated with a single injection of 0.3 gm. or more were cured. 'Twenty patients in a group of 22 cases treated with 0.2 gm. were cured, and only two of five cases treated with a single injection of 0.1 gm. were cured'.

'The failures were re-treated successfully by the following means: two of the failures with 0.1 gm. were cured by re-treatment with 300,000 units of penicillin in peanut oil and beeswax, and another of these failures was cured with 0.2 gm. of streptomycin. The two failures with 0.2 gm. were cured by re-treatment with 0.2 gm. of streptomycin'.

'Toxic reactions were relatively mild. Some patients complained of pain for several hours at the site of injection. No skin reactions were noted in any case. In two cases typical Herxheimer reactions occurred and in these the blood serologic tests for syphilis were subsequently found to be positive'.

Studies on Chancroid. III. Ducrey Skin Reactions in Negro Hospital Patients

By A. HEYMAN,

and

P. B. BEESON

(Abstracted from the *Journal of Venereal Disease Information*, April 1946, Vol. 27, p. 104)

DUCREY skin tests were done on 473 Negro hospital patients. It was found that 29.5 per cent of adults showed positive skin reactions, while none of 87 children reacted positively. Positive skin reactions began to appear in individuals between the ages of 15 and 24 years. The incidence then rose in succeeding decades, but declined slightly in patients older than 55 years. Positive skin tests occurred at an earlier age in female than in male patients and were more common in syphilitic than in non-syphilitic individuals. The considerable number of positive reactions found in individuals belonging to the older age groups indicates that the skin reactivity remains for many years after its

development. The presence of positive skin reactions in more than one-fourth of the Negro population in this vicinity limits the diagnostic usefulness of this test to a considerable degree.

No attempt was made to obtain a history of chancroid or to demonstrate existing infection among the subjects tested.

The foregoing evidence that the age incidence of development of positive Ducrey skin reactions corresponds with the period of greatest sexual activity suggests that the reaction is a specific one. On the other hand, the number of persons giving positive reactions is far higher than could be accounted for by the incidence of recognized chancroid in the same population. It is possible, however, that subclinical chancroid infections are relatively common, as in the case with many other infectious diseases. It is also possible that positive skin reactions may result from the presence of Ducrey bacilli on normal genitals.

Reiter's Disease

By P. N. BARDHAN

(Abstracted from the *British Medical Journal*, 5th July, 1947, Vol. II, p. 32)

THE author draws attention to his four cases, none of which had any relationship with bacillary dysentery. Further, in India, bacillary dysentery cases are seen literally by thousands, and yet there are no authentic records of Reiter's disease. Had the two conditions been aetiologicaly related there would surely have been more cases of Reiter's disease in this country.

The categorical statement made that '... there is no relation to sexual intercourse' is not wholly correct. Kristjansen described his case in detail in 1930 where the infection was traced to a girl of 16 who for two years had had a yellow vaginal discharge. This girl had also infected another man at about the same time, and the second victim developed only an uncomplicated urethritis lasting three months. In neither man was the gonococcus or any other organism found. The girl herself was examined and found to have had only an inflamed vagina, but gonococci were not demonstrated in her either. The sexual relationship in these two cases is clear. One of the four cases also developed the condition after extramarital coitus.

Neutrophil leucocytosis has been reported in all the cases, but one had an eosinophilia of 4 to 7 per cent in a total leucocyte count of 11,000 to 13,000. This may mean that allergy is a factor in the disease. This case went through the gamut of bilateral conjunctivitis and polyarthritis, and the eosinophilia persisted over the earlier part of the illness. The patient did not have any parasitic infection or infestation. The possibility of allergy being aetiologicaly responsible is strengthened by the observation of Forbes that his case was associated with dental

sepsis. Junghans tells about a case in conjunction with a furuncle in the upper lip, while Fruehwald described two cases, in one of which the first sign was urethritis and in the other, joint pain in the left foot. The example of erythema nodosum being the result of a variety of infective processes may be mentioned as a possible parallel to the incidence of Reiter's disease following upon non-specific infections.

In none of the four cases observed was the complement-fixation test for gonococci done, but gonococci were not found in any of the exudates by the usual staining methods. The tests were repeated many times and under varying clinical conditions.

The Herxheimer Reactions of Relatively Small Doses of Penicillin

By S. OLANSKY

(Abstracted from *Bulletin of Hygiene*, Vol. 22, No 6, June 1947, p. 400)

Six cases are presented in which severe Herxheimer reactions followed the injection of 1,000 units of penicillin. Therefore penicillin, even in small doses, should not be administered to patients with late or complicated syphilis as such reactions may be disastrous until a course of bismuth has been given.

A. B. R. C.

Penicillin in the Treatment of Syphilis in Children

By JOSEPH YAMPOLSKY, M.D.,

and

ALBERT HEYMAN, M.D.

(Abstracted from the *Journal of the American Medical Association*, 19th October, 1946, p. 368)

CONGENITAL syphilis is often severer than the acquired infection. Doses of penicillin comparable to those effective in adults are not entirely satisfactory in the treatment of the infantile infection, and further investigation of this problem is necessary.

The result of penicillin treatment of syphilis in children varies considerably and depends on the type and duration of the infection.

Sixty-one children with various manifestations of syphilitic infection were treated with penicillin. The drug appears to be an effective agent in the treatment of infantile congenital syphilis, and satisfactory results were obtained in 23 of 32 children treated for this condition.

Seven of the children have been followed for four to eight months, while 22 children have been observed for twelve to twenty months. The remaining 3 patients died soon after treatment.

These 23 children now present a normal response to the serologic test or have a steadily decreasing titre. All of them are clinically well, have normal spinal fluids and exhibit no clinical symptoms of the disease. Four children have persistently positive Kahn tests sixteen months after treatment. These patients were older than 4 months at the onset of treatment, and their sero-resistance is believed to be the result of late diagnosis and treatment.

The writers do not believe that the 3 fatalities in this series are related to penicillin therapy. Two of the deaths apparently resulted from an overwhelming syphilitic infection in premature and malnourished infants, while the third fatality remains unexplained.

The results obtained in this study indicate that penicillin is an effective agent in the treatment of infantile congenital syphilis. Although the optimum dosage of penicillin cannot be determined in such a small series of cases, the writers believe that a total dose of penicillin of 100,000 units per kilogram of body weight is effective in the treatment of the majority of these cases.

The serologic test for syphilis often became normal in three to six months, but patients with originally high titres sometimes required nine to fourteen months for a complete serologic reversal to occur.

Herxheimer reactions occurred in approximately one-half of the cases. These consisted of sharp elevations of temperature, which did not appear to be injurious to the child. These reactions occurred despite the administration of the drug in gradually increasing doses. No other reactions were observed.

Nine patients with interstitial keratitis were also treated with penicillin.

Each patient was given approximately 50,000 units of penicillin per kilogram of body weight, intramuscularly, in equally divided doses every three hours for seven and one-half days.

The serologic titre of most of these patients fell slightly, but no reversals of the serologic test have thus far been observed. In only one of these patients did penicillin therapy achieve excellent results, with the return of near-normal vision. All the others continue to show moderate to severe visual impairment. Although penicillin solution was instilled locally in several patients, this procedure did not seem to improve the results of treatment.

The results obtained in the treatment of interstitial keratitis indicate that this condition is refractory to parenteral penicillin therapy. The poor response of this manifestation to all forms of antisiphilitic therapy has long been observed. Recent work has indicated that the refractoriness of interstitial keratitis to treatment is due to the lack of vascularity of the cornea and the low concentration of the antispirechætal agent in the cornea. Although satisfactory concentrations of penicillin in the ocular tissues are said to occur after the local instillation of penicillin,

this form of therapy did not improve the results in their cases.

No response was obtained in any of the patients with Clutton's joints who were treated with parenteral penicillin. This type of arthritis is also refractory to routine anti-syphilitic treatment.

Acquired syphilis in children seemed to respond readily to doses of penicillin comparable to those used in adults, i.e. 40,000 units per kilogram of body weight.

Six patients with late congenital asymptomatic neurosyphilis were also treated with penicillin. Most of these patients had received adequate arsenic and bismuth therapy previously with no apparent effect on the spinal fluid observations. The age of these patients at the onset of treatment ranged from 10 to 25 years. The spinal fluid in the majority of these patients had group III findings, showed a strongly positive Wassermann test with an elevation in the cell count and the protein level, and the mastic curve reaction.

These patients received a total dosage of 40,000 units of penicillin per kilogram of body weight in seven and one-half days.

Four patients have obtained a satisfactory spinal fluid response and the mastic curve, protein level and cell count are normal one year after treatment. The spinal fluid response to the Wassermann test in each of these patients is still positive, but there has been a reduction in titre.

The changes in the spinal fluid in late congenital asymptomatic neurosyphilis were in general satisfactory and comparable to those obtained with fever therapy.

Two patients with juvenile paresis were treated with penicillin alone. Neither of these children displayed much clinical change, but the spinal fluid indicated some improvement.

Two children with recent progressive eighth nerve deafness were also given penicillin, and doses of 100,000 units per kilogram of body weight were used. No change was observed in the severer case of deafness three months after the completion of therapy. In the milder case, however, some improvement in hearing has occurred.

L'Étiologie de la Repression de L'Inceste (The Etiology of the Repression of Incest)

By MARC LANVAL, D.S.S. (Pp. 416). Brussels
(Abstracted from a review by V. R. Khanolkar,
M.D., in *Marriage Hygiene*, Vol. 1, No. 1,
August 1947, p. 34)

The thesis developed by Lanval is suggestive and may be briefly stated.

1. Human instincts are essential components of man's intimate make-up. There is therefore

a constant urge in him to satisfy them. The sex instinct is probably the most insistent, and the urge for its satisfaction is often tyrannical. Man is lazy and improvident by nature, he shuns effort as much as possible and seeks the easier way out of his difficulties. As sex instinct is probably present from the moment of birth, the infant and the child encounter the first objects of their desire and jealousy in their immediate surroundings. With the awakening of the sex desire at puberty, the adolescent is tempted to seek someone to share his erotic games in his family group. This is the easy way out for his longings as it facilitates the search, the approach and conquest of a participant. Incest holds out easy possibilities for the gratification of an urge and humanity carries in its soul an undeclared partiality for a simpler procedure.

2. Sex instinct demands vigorous excitation for its full satisfaction. Such excitation could only be provoked by an unfamiliarity with the person desired. The members of a family or a group living or working together are often incapable of such stimulation by reason of their proximity and banality. This leads to an indifference between different members of the group so far as sex relationship is concerned and if any individual pursues his courtship towards an unwilling partner, the act is considered obscene and evokes violent repulsion in most instances.

These two opposite tendencies of sex attraction and repulsion explain the dimorphic response in a family group to the fulfilment of a primitive instinct. The laws regulating marriages in a community and the concessions and dispensations earned from time to time represent a compromise between these tendencies and the relative dominance of one or the other under the particular circumstances.

3. Human communities constantly endeavour to maintain peace and harmony among its members by restricting the liberty of the individual in several acts which affect the society. They try to ensure a continuity of the group by inculcating notions of respect for authority and to preserve unity in the group by fostering a loyalty to it. The sex instincts of the individual are similarly restrained to avoid the jealousies and the disruptive effects of incest in the group. Repressions are techniques direct and indirect, sacred and profane, to enforce certain restrictions as there is a constant and subconscious urge to break through them. The number, the extent and the rigidity of these restrictions are primarily dependent on the sense of solidarity in the family or the community and the strength of family ties between the individual members.

4. The restrictions and prohibitions regulating marriage and the repression of incest are a social technique to preserve the prestige of authority and are a pledge for its continuity.

Studies on Lymphogranuloma Venereum Complement-Fixing Antigens

By MAURICE R. HILLEMANN

and

CLARA NIGG

(Abstracted from the *Journal of Immunology*,
Vol. 53, June 1946, p. 201)

THE demonstration of a certain community of antigen has served as a basis for including a number of viruses in one group referred to as the psittacosis-lymphogranuloma venereum group. Among the viruses included in this group are those of psittacosis, ornithosis, lymphogranuloma venereum (LV), mouse pneumonitis, meningopneumonitis, feline pneumonitis, and human pneumonitis, and Illinois.

The purpose of this paper is to describe an ether soluble fraction whose reactivity in complement-fixation tests apparently was identical to that of the initial infected yolk sac suspension.

In view of the protein-polysaccharide-lipid complex characteristic of certain fractions of gram-negative bacteria (24-26) it seemed possible that the lymphogranuloma venereum complement-fixing antigen might also contain such a complex.

Samples of freshly prepared LV suspension, each of which contained 20 per cent yolk sac with or without urea and/or phenol, were extracted with anæsthetic ether after 3 weeks of refrigeration.

Six volumes of anæsthetic ether were added to each suspension which was shaken briefly and placed in the refrigerator overnight after which the supernatant ether was removed. A second extraction was made in the same manner. The two ether extracts were pooled and concentrated to twice the volume of the original suspension, resulting in a volume equivalent to 10 per cent yolk sac suspension. The pooled extracts were stored in the refrigerator.

For use, 2.0 ml. of extract were concentrated by evaporation in the 56°C. water bath to about 0.2 ml. which left sufficient ether to keep the lipids in solution. Two ml. of saline were then added to the concentrated volume. By shaking the saline suspension in the water bath at 56°C. the ether was evaporated to a volume at which it would theoretically be completely soluble in the amount of the saline solution used. Satisfactory saline suspensions could never be prepared from ether extracts which had been evaporated to dryness. Analogous fractions were prepared from normal yolk sac suspension. All antigens were kept sterile throughout their preparation.

It will be seen from the results presented in table I that not only was the complement-fixing activity quite completely extracted from untreated and urea-treated parent suspensions, but the titre of the ether extracts was 1 : 800 as compared to 1 : 200 of the respective parent

suspensions, representing a fourfold enhancement. Analogous fractions prepared from normal yolk sac suspensions showed no complement-fixing activity.

It should be noted that the suspensions used in the experiments described in this paper had been aged for three weeks which seems to be necessary to effect the complete extraction of the complement-fixing activity with ether.

Even strongly anticomplementary suspensions yielded ether extract antigens which were not at all anticomplementary. The ether extract of the phenolized suspension was not more active than the parent suspension. Preliminary treatment with phenol prevented enhancement of the ether extract.

A zone phenomenon was noted with the 1 : 100 dilution of the ether extracts. This zoning effect was occasionally noted in titrations of LV sera and antigens.

The ether extract antigen was investigated by comparing this antigen with phenolized antigen in tests with sera from human beings infected with psittacosis, ornithosis and LV and with one serum from a Wassermann-negative laboratory worker.

Table II shows that the ether extract and phenolized antigens were fixed to about the same degree with psittacosis and ornithosis serums as well as with LV serum but not with normal sera. No fixation occurred in tests with the corresponding normal control antigens. These results show that although ether extraction effects a considerable purification, this antigen nevertheless retains its group reactive character.

Several factors appeared to determine the degree of enhancement of the ether soluble fraction. Ageing of the suspension was of first importance. Maximal dispersion of extract antigen in saline solution also appeared to determine the degree of demonstrable enhancement.

Although the chemical nature of the extract antigen is not known, it seems to be similar in some respects to the glucolipids obtained from bacterial cells. A carbohydrate nature was previously suggested in view of the fact that antigens in the form of whole yolk sac suspensions are stable to boiling and even autoclaving under certain conditions. While the solubility of the antigen in ether might suggest a lipoidal nature, the authors recognize the possibility that the antigen may be more apparent than real. Possibly the antigen is carried into the ether because of its union with certain yolk lipids. Whether the complement-fixing antigen would be soluble in ether if the virus were grown in the absence of yolk lipids is under investigation.

The extract antigens are superior to crude suspensions in several respects: (a) They are much less turbid. (b) They have never been anticomplementary. (c) Satisfactory ether extract antigens may be obtained from highly anticomplementary suspensions.

Maximal enhancement in the ether extract depended on (a) preliminary ageing of the yolk sac suspensions, (b) degree of dispersion of the extract in saline solution, and (c) absence of phenol.

Lymphogranulomatous Strictures of the Rectum

(Reprinted from *Medical Newsletter* No. M349, dated February 1947, prepared by the American Medical Association)

STRICTURES of the rectum due to lymphogranuloma venereum are a serious threat to life in some instances. Negro women are chiefly affected. Some conditions are mild and seem to cure themselves. Other conditions progress in spite of all known methods of treatment. It is the authors' opinion that these variations in clinical behaviour result from the fact that there are different strains of the virus and that the virus produces a reaction according to the host. The early diagnosis and treatment in all cases is important.

In the pre-stricture stage sulphonamide compounds seem to have some value, but there is a question as to whether sulphonamide drugs can prevent permanently an extension of the processes in some cases. It is likewise true that in some of the instances in which sulphonamide drugs seem to have been of value the evidence is not conclusive as yet that these patients might not have done as well without the sulphonamide compounds as far as checking the activity of the virus is concerned. Sulphonamide drugs do help in clearing up the secondary superimposed infections that are present in these cases and thus improve the condition of the patient clinically. Penicillin has proved valueless in our hands.

Once a fibrous stricture has occurred, drugs are of value only by elimination of the toxic effect of secondary bacterial invasion due to the fact that the blood supply to and through the dense scar tissue is so lessened that no adequate therapeutic concentration of the drug is possible. Some conditions do not progress rapidly and are not serious, while other conditions do progress rapidly in spite of all forms of treatments, with the exception of early excision. Colostomy helps many patients (1) by lessening secondary infection and (2) by overcoming the toxic effects of chronic obstruction of the bowel.

Surgical treatment alone is of value once a fibrous stricture of any considerable extent is developed. Warthen's obliteration of the cul-de-sac operation offers the possibility of lessening the complications that are inherent in colostomies, namely, anterior grade and retrograde herniation. It cannot, however, prevent stenosis of the colostomy opening, which occurs in many instances. Pauchet's excision operation or a modification thereof at this time offers the best method of cure for strictures low in rectum. This does not exclude the sacroperineal excision

operation of Hartmann. These operations are of such magnitude that they should be performed only by experienced surgeons.

When the disease involves the entire rectum or is high in the rectum, involving the recto-sigmoid area, abdominoperineal extirpation is indicated if the patient's clinical condition does not improve after colostomy. In the rare cases in which the descending colon is involved, a permanent artificial anus in the transverse colon should be made. Carcinoma occurs as a superimposed factor in a sufficiently large number of cases to be of clinical significance.

(Wright, Louis T., et al.: Lymphogranulomatous Strictures of the Rectum, *Am. J. Surg.*, 53, 499, November 1946.)

Medicolegal

A MISPLACED LABEL

DEATH FROM BARBITONE POISONING

(Abstracted from the *Pharmaceutical Journal*, Vol. 158, 29th March, 1947, p. 199)

An inquest was held at Birmingham on a 48-year-old man who had died from barbitone poisoning, due to an error on the part of the chemist, who had affixed the wrong label to the box. A verdict of accidental death was recorded.

The doctor said that he prescribed 36½ gm. tablets of M&B 760, four to be taken at once and two every four hours afterwards, and 24 barbitone tablets, to be taken two each evening to assist sleep. He found that the directions on the boxes had been transposed, and it appeared that the chemist had labelled the boxes wrongly. The wife had been inadvertently giving her husband the barbitone tablets instead of the M&B, and in all he had had sixteen tablets of barbitone.

The Coroner said it was quite clear that Holloway had made a mistake, and he admitted it. There was a human element in everything, and there was no gross or culpable negligence on Holloway's part, or any intention of doing anyone any harm. He was doing his best to do his job, but he had made a fatal mistake. The system he had used was not foolproof, and it seemed that in dealing with dangerous drugs they should be dealt with separately. As far as the court was concerned there was no suggestion of criminal negligence.

A. B. R. C.

A LONG GESTATION PERIOD

(From the *British Medical Journal*, ii, 5th July, 1947, p. 36)

ENGLISH law dislikes rigid rules of evidence binding the court to presumptions of fact. For instance, whereas the law of several foreign countries lays down limits for the possible period of gestation, our law knows no such limits and our courts have consistently refused to fix one. In the case of *Clark v. Clark* the President, Lord Merriman, refused to hold that a child was illegitimate which survived after an apparent pregnancy of 174 days. At the other end of the scale the court held in *Gaskill v. Gaskill* that 331 days was not too long a pregnancy to admit as possible. Even this record was broken in the recent case of *Wood v. Wood*.

A wife summoned her husband before the justices for desertion. The husband's defence was that he was

Effective and Low Dosage Sulphonamide Therapy

with

IRGAFEN

(N,3,4-Dimethylbenzoyl Sulphanilamide)

A well tolerated chemotherapeutic agent with definite action.
Total dosage 30-50% lower than that of other sulphonamides.

Indications :

Pneumonia, meningitis, B. coli infections, strepto- and staphylococcal infections, dysenteric enterocolitis, etc.

Tablets — Ampoules

Asthenia

The incidence of asthenia and malnutrition demands a preparation of proved tonic powers which is admirably provided in Waterbury's Compound. The intake of this preparation, which contains as its components products obtained by the enzymatic action of pancreatic ferments on cod liver oil, livers and spleens, malt extract and hypophosphites, results in the stimulation of physical vigour and disappearance of the signs of inanition. Waterbury's Compound is agreeable to the palate and is suitable for administration to patients of all ages.

W

ATERBURY'S

COMPOUND

Intestinal Toxæmia with Hypertension Gastric Fermentation and Distension

Charkaolin is a highly efficient, gas-absorbing and toxin-adsorbing agent, in which two medicaments with complementary actions are associated. It combines a highly-activated vegetable charcoal and Osmo Kaolin, an exceptionally colloidal form of Kaolin prepared by a special process of electro-osmosis.

The therapeutic applications of Charkaolin include flatulence, diarrhoea, colitis, and dysentery. It has been found useful in some cases of high blood-pressure associated with intestinal toxæmia. Charkaolin has proved highly successful in removing gas from the intestines before intravenous urography and before cholecystography.

CHARKAOLIN

In bottles containing approximately 6 ozs.

ALLEN & HANBURY'S LTD. • CLIVE BUILDINGS • CALCUTTA

HÆMOSAN

with Liver and Vitamins

In the treatment of anaemia

Haemosan tablets contain freely ionisable Iron, in the form of Exsiccated Ferrous Sulphate, in combination with Liver Extract supplemented by Vitamins B and C together with traces of Copper and Manganese in the form of Sulphates.

This combination is recognised as the most effective for the administration of Iron and it produces optimum haemoglobin response with minimum dosage. The Copper and Manganese assist the Ferrous Iron in the formation of haemoglobin by their catalytic action.

Vitamin C greatly enhances the therapeutic

properties of Liver Extract and they have both been incorporated in these tablets in order to give the maximum effect.

Haemosan with Liver Extract and Vitamins can confidently be recommended and prescribed in any condition in which a deficiency of haemoglobin exists.

As the tablets are Enteric coated, the Ferrous Sulphate remains quite unaffected by atmospheric oxidation.

not bound to continue to live with his wife because she had committed adultery. Evidence was given of the last date on which the couple actually cohabited, and of the birth of a child, fully grown and somewhat over the average weight, 346 days afterwards. The husband called no evidence of any association between the wife and other men, but maintained solely in view of the length of the gestation that the child could not be his. The magistrate, rightly considering that the allegation of adultery is serious and must be strictly proved, refused to assume adultery on the gestation period alone, but accepted the evidence of the wife denying it.

The president of the Divorce Court, hearing the husband's appeal, agreed that there must come a point at which any judge must take judicial knowledge of the fact that the period is altogether outside what is possible, and also that one case or another must be on the wrong side of any line that can possibly be drawn. He absolutely declined however, on the information before the court, to say that it was bound to hold that 346 days was on the wrong side of any line that could possibly be drawn and that the wife had committed adultery. The court also held that, although the husband believed that the wife had committed adultery and that he was not the father of her child, he had nevertheless deserted her, because his belief was not induced by such an act on her part as would lead a reasonable person to believe that she was guilty of adultery. It therefore upheld the order of the justices requiring the husband to maintain the wife.

Reviews

ESSENTIALS OF MEDICINE.—By Charles Phillips Emerson, Jr., A.B., M.D., and J. E. Taylor, R.N., B.S., M.Ed. Fifteenth Edition. 1946. J. B. Lippincott Company, Philadelphia and London. Pp. xxii plus 688, with 201 illustrations in black and white and 4 coloured plates. Price, 21s.

This book was first written forty years ago with the object of giving medical students and nurses a general idea of diseases, their treatment and nursing care before they proceeded to more advanced studies. It was not meant as a textbook on medicine but written expressly for beginners so that they may gain as their first impression a clear mental picture of the subject. Judging from the number of editions that have since appeared at regular intervals, it must be fulfilling its purpose well indeed. The present edition has been extensively revised and includes many advances in medicine that have taken place in recent years, e.g. modern methods of chemotherapy, the use of blood and blood substitutes and treatment of various deficiency syndromes. Nursing receives a good deal of attention, and though a description of its technical details is not within the scope of the book, the essential elements have been described in connection with the diseases discussed. The last chapter is a new one and summarizes, in outline form, basic facts concerning therapy, prevention and nursing care of the important diseases. The text has been reset in double column and there are many illustrations. The book presents its material with simplicity and clarity and deserves to be better known in India.

R. N. C.

CHEMICAL METHODS IN CLINICAL MEDICINE: THEIR APPLICATION AND INTERPRETATION WITH TECHNIQUES OF SIMPLE TESTS.—By G. A. Harrison, B.A., M.D., B.Ch. (Cantab.), M.R.C.S. (Eng.), L.R.C.P. (Lond.), F.R.I.C. Third Edition. 1947. J. and A. Churchill Limited, London. Pp. x plus 630, with 5 colour plates and 120 illustrations. Price, 40s.

The main object of the book is to promote the development of a more intimate relationship between

chemistry, physiology and medicine and the perusal of the book will convince the reader that the labours of the author have been well spent in that direction.

The book has been thoroughly revised and the revision of some parts such as the section on cystinuria, clearance tests and liver efficiency tests appears to be very extensive indeed. Many new items have also been included in the present edition but the size of the book has not been much altered evidently due to drastic editing.

The first chapter would prove to be very useful from the point of view of diagrams and detailed notes about apparatus and special instruments such as colorimeters, comparators, microscope, spectroscope, etc.

A new and a very useful chapter (chapter XXVIII) has been added on pigmentation and is illustrated by coloured plates. An entirely new section on sulphonamide and its derivatives describing tests which would help to adjust the dose of the drug in order to maintain an effective concentration in the blood plasma has been added. A useful modification of Yvon's hypobromide method for estimation of blood urea has been described by the author where he has substituted a syringe for the rubber bulb, which appears to be an improvement in that it is easier and safer to handle. Similar additions are found in the sections on aetiology of calculosis, analysis of post-mortem blood and cerebrospinal fluids, copper sulphate, S. G. method of proteins, etc.

J. P. B.

THE M.B., B.S. FINALS. A COLLECTION OF THE PAPERS SET AT THE LONDON M.B., B.S. EXAMINATION FOR THE YEARS 1932-1945, CLASSIFIED AND ARRANGED IN SUITABLE SUB-DIVISIONS.—By F. Mitchell-Heggs, T.D., M.B., B.S. (Lond.), F.R.C.S. (Edn.), Major, R.A.M.C. Third Edition. 1947. J. and A. Churchill Limited, London. Pp. xvi plus 99. Price, 8s. 6d.

This is a collection of the papers set at the London M.B., B.S. examination for the years 1932-1945, classified and arranged in suitable sub-divisions. It also includes extracts from Regulations relating to degrees in medicine and surgery of the University of London. The volume will be of service to those working for the final medical examination.

R. N. C.

THE DOCTOR AND THE DIFFICULT ADULT.—By William Moodie, M.D., F.R.C.P., D.P.M. 1947. Cassell and Company, Limited, London. Pp. vii plus 286. Price, 15s.

This book is intended for the ordinary doctor who wishes to acquire a general knowledge on modern psychiatry but who has neither the time nor the inclination to read the more elaborate textbooks on the subject. At the outset the author defines the scope and limitations of psychotherapy and then proceeds to describe in non-technical language and with many illustrative cases the common mental disorders, e.g. dementia præcox, schizophrenia, anxiety neurosis, obsessional states, hysteria, neurasthenia, epilepsy and mental defect. Then follows a chapter on the planning of interviews between the psychiatrist and his patient on which so much depends towards the progress of the case. Treatment in itself is divided into two parts, general, including medical, surgical and shock therapy and narco-analysis, and psychological, in which sufficient details are given of the principles and management of the patient. The last chapter is on the 'healthy person', i.e. on mental health, a subject which has attracted a good deal of attention in recent years and in which the author makes some common-sense observations. The book is obviously based on his own clinical experience, and being free from jargon and theoretical discussions, it is quite suitable to general practitioners.

R. N. C.

A TEXTBOOK OF BACTERIOLOGY.—By R. W. Fairbrother, M.D., D.Sc. (Man.), F.R.C.P. (Lond.). Fifth Edition. 1946. William Heinemann (Medical Books) Limited, London. Pp. viii plus 480. Illustrated. Price, 17s. 6d.

In the new edition this textbook has been thoroughly revised. The many important developments in bacteriology made during recent years have been incorporated and obsolete material removed. Each chapter is complete and written in a simple lucid language which makes for easy reading and is eminently suitable for the medical student. This textbook is recommended as one of the best amongst the large number available on the subject.

C. L. P.

GENERAL BACTERIOLOGY: LABORATORY MANUAL.—By L. S. McCune. 1946. W. B. Saunders Company, Philadelphia and London. Pp. ix plus 106. Illustrated. Price, 6s. 6d.

This manual is designed as a work book of laboratory exercises for classes in bacteriology. The sixty-one exercises illustrate the fundamental principles of practical bacteriology. Each exercise is on a uniform plan—following a brief description of the purpose of the exercise and the list of the materials required for it the procedure of work is given in detail. Space is provided for further notes and to record the results in well-designed blank forms. At the end of the book are four useful appendices dealing with the microscope, stains and reagents, culture media and notes on general laboratory technique. This manual will be of value not only to the student but also to the teacher who will find in it much that will help him in planning the practical class work of introductory bacteriology.

C. L. P.

HANDBOOK OF PRACTICAL BACTERIOLOGY: A GUIDE TO BACTERIOLOGICAL LABORATORY WORK.—By T. J. Mackie, C.B.E., M.D., D.P.H., and J. E. McCartney, M.D., D.Sc. Seventh Edition. 1945. E. and S. Livingston, Limited, Edinburgh. Pp. viii plus 720. Illustrated. Price, 17s. 6d.; postage, 7d.

Since its first publication in 1925, this popular and trusted book of practical bacteriology through its various editions has been available as an up-to-date book of study and reference. In the present edition are incorporated new contributions to bacteriological knowledge and technique developed during the war. Much of this is contained in the appendix—a feature introduced in the sixth edition—which reviews and stresses the importance of the advances made during recent years.

This new edition fully maintains and enhances the high reputation of its predecessors and can be recommended as one of the best books on practical bacteriology.

C. L. P.

AIDS TO BACTERIOLOGY.—By H. W. Scott-Wilson, B.Sc., B.M., B.Ch. (Oxon.). Seventh Edition. 1946. Baillière, Tindall and Cox, London. Pp. vii plus 300. Price, 6s.

This seventh edition of this number of the Student Aids Series has been revised and by the deletion of old and unimportant material new matter has been introduced without any material change in the size of the book. A great deal of obsolete and unnecessary material still remains and certain important groups of organisms are inadequately described. As an example of obsolete material it is stated in the chapter on cholera that in the bacteriological diagnosis of the disease amongst other tests the pathogenicity of the organism is determined by intraperitoneal inoculation of a guinea-pig which if the organism is *V. cholera* will die in 24 hours (p. 158) and on the next page 'the vibrio is identified with certainty by the agglutinin absorption test and by Pfeiffer's reaction'. The generally accepted definition of the cholera vibrio is nowhere given. The group of organisms of particular

interest in the tropics are as a whole inadequately dealt with. This is a book that cannot be recommended to the medical student of India.

C. L. P.

PRACTICAL HANDBOOK OF THE PATHOLOGY OF THE SKIN.—By J. M. H. Macleod, M.A., M.D., F.R.C.P. (Lond.), and I. Muondo, M.R.C.P. (Lond.), M.B., B.S., B.Sc. (Lond.). Third Edition. 1946. H. K. Lewis and Company, Limited, London. Pp. xix plus 415, with 27 coloured and 125 black and white illustrations. Price, 50s.

This third edition of this valuable and useful book for students of dermatology and pathology has been revised and certain sections amplified. The sub-title—an introduction to the histology, pathology, bacteriology and mycology of the skin with special reference to technique—indicates the scope of this work. It is more than an introduction, it is a complete description. All the important information necessary for the serious student of dermatology is contained in this book. The illustrations of which there are 27 coloured and 125 black and white are excellent and enhance the value of the descriptions. This is a work that will be of great value to all workers in dermatology and pathology.

C. L. P.

MATERIA MEDICA FOR NURSES: A TEXTBOOK OF DRUGS AND THERAPEUTICS.—By W. Gordon Soars, M.D. (Lond.), M.R.C.P. (Lond.). Second Edition. 1947. Edward Arnold and Company, London. Pp. vii plus 246. Price, 5s.

The textbook *Materia Medica for Nurses* should be of great value to all nurses in training. It is written clearly and concisely and includes information about the latest drugs. The chapter on weights and measures and the table of vitamins are particularly useful, but in the new chapter on penicillin there is no mention of its use as a throat spray and inhalation in cases of bronchiectasis. Student nurses studying this book will have a clear understanding of drugs in daily use.

I. S.

ANATOMY AND PHYSIOLOGY FOR NURSES.—By J. L. Hamilton-Patterson. 1946. H. K. Lewis and Company, Limited, London. Pp. vii plus 173, with 102 illustrations. Price, 9s.

ANATOMY AND PHYSIOLOGY FOR NURSES is a well-planned textbook. The diagrams, 102 in all, are exceptionally clear and the appendix giving the meaning of anatomical words is most useful. It is one of the few textbooks of its kind that describe anatomy and physiology as a whole, and not in the old-fashioned way of one system at a time.

I. S.

AIDS TO TROPICAL HYGIENE.—Edited by Nicholls Lucius, C.M.G., M.D., B.C., B.A. (Cantab.). Third Edition. 1946. Baillière, Tindall and Cox, London. Pp. xli plus 217. Illustrated. Price, 6s.

COMMENCING from small beginnings the scope of public health as an organized community effort has progressively expanded almost indefinitely. To encompass such a vast field within less than 220 small sized pages is indeed a great task and this small book accomplishes this task admirably. Obviously it was necessary to omit much desirable matter and specially the details which were of particular interest to early sanitarians and which used to form bulk of old standard books. In making his selection the author has exercised good judgment. It should, however, be understood that these remarks apply in respect of public health in Great Britain, not in our own country. There is indeed considerable amount of basic knowledge which is of interest to public health workers all over the world but as an organized community effort, public health must take different courses in accordance with local requirements. The book should, however, serve as a model for our Indian authors to present factual

data and practices in an authoritative, accurate and concise form, with a discussion of principles.

Abstracts from Reports

ANNUAL REPORT ON THE WORKING OF THE ASSAM MENTAL HOSPITAL, TEZPUR, FOR THE YEAR 1945. BY S. L. BHATIA, C.I.E., M.C., M.D., F.R.C.P., I.M.S., INSPECTOR-GENERAL OF CIVIL HOSPITALS, ASSAM

THE total number of patients treated during this year was 700 (606 males and 94 females) including 558 remaining from the previous year. Of this number 9 were discharged cured, 26 were discharged improved and 31 died. The daily average strength was 588. Schizophrenia including dementia præcox and mental depression insanity were the commonest causes of the disorders. Patients were employed in gardening and miscellaneous jobs. The proposal for appointment of an occupational therapist is under consideration. The institution has a high rate of sickness and mortality. Of the 31 deaths 6 were due to dysentery and 6 to tuberculosis. In the previous two years these two diseases had caused 117 and 55 deaths respectively. Obviously sanitation is in bad state; the water supply is as insufficient as two decades ago, there is no provision for segregating dysentery cases, disinfection is in a very unsatisfactory state, and there is

constant absconding of keepers and sweepers. Other needs of the institution are convalescent home, a recreation hall with library, provision of nurses and sisters, and increase in the superior staff. The Inspector-General of Civil Hospitals concludes, 'This institution, though styled Mental Hospital, is still in mixed state of prison, an asylum and a mental home. In order to modernize it a good deal of improvement is necessary. . . . The attitude of the general public towards lunacy is still very crude and the medical profession for lack of sound training is inclined to look upon psychiatry as a kind of pathological curiosity; so a propaganda programme to educate the public and to cope with the apathy and lack of understanding in the medical profession is the first essential thing'. (And may we suggest that three rupees is too high a price for a report of 16 pages?)

R. N. C.

ANNUAL REPORT OF THE PROVINCIAL BLOOD TRANSFUSION SERVICE (BLOOD BANK), MEDICAL COLLEGE HOSPITAL, CALCUTTA, 1945-46

THIS service was inaugurated in 1924 in the Imperial Serologist's Laboratory, Calcutta, and later expanded and formed, with the collaboration of the Red Cross Society of Bengal, into what constituted the first blood bank in India. In 1941 it was taken over by the Government of India, enlarged for war purposes and housed in the All-India Institute of Hygiene and Public Health, Calcutta, and in 1945 it was handed over to the Government of Bengal for peace-time work. Its report for the year 1945-46 has just been issued.

The Blood Bank which is now situated in the Calcutta Medical College is open daily at certain hours to emergency cases. Blood is supplied to hospital patients (civil and military) either in exchange for blood donated to the bank or on payment of a fee of Rs. 25 to Rs. 40, but during the year a large quantity of blood was supplied free to indigent patients. Stocks of serum have been issued to meet emergent requirements in the more important hospitals. Training in transfusion is given to doctors, the course extending over a full week. A panel of trained doctors is kept from willing private practitioners, and these are recommended when a request is received for transfusion at a private house.

Much propaganda work has been necessary to make the organization a success, and among other measures Red Cross badges and bars indicating the number of bleeding are awarded to donors. A donor becomes eligible for a silver medal after ten donations of blood, and the award is made at a formal ceremony at Government House. The last investiture ceremony was held in January 1946 when 42 donors were presented with silver medals. Here it is worth mentioning the name of Captain M. Sh. C. Hannah who donated blood 50 times since 1942. Another donor transferred from the Bombay register donated 139 times. None of them had any ill effects. During the year 6,835 donors were bled and half of them were military personnel. Other sources were blood bank clinic, special clinics (i.e. special collection centres to suit the convenience of donors), mercantile firms and jail convicts. During the Calcutta disturbances about 400 students donated their blood in response to appeals issued through the press. In addition a panel of donors was maintained for catering to the needs of those who preferred to use blood directly from donors instead of stored blood or blood substitutes. There are about 122 donors on the panel who charge Rs. 50 from the patient for one donation of 300 c.c. of blood.

During the period under review out of 1,614 litres collected 381 litres were issued for whole blood transfusion and 1,233 litres were processed into serum. The demand has been much in excess of the supply, it is now encroaching on the reserve stock. The zeal to donate has slowed down since the termination of the war and of late the bank has been dependent mostly on the military and jails, but here too difficulties are

being experienced. The sale proceeds show that patients are quite willing to pay, but unless the public realize their responsibility, the blood bank cannot maintain its solvency for long.

R. N. C.

SIXTY-FIRST ANNUAL REPORT OF THE NATIONAL ASSOCIATION FOR SUPPLYING MEDICAL AID BY WOMEN TO THE WOMEN OF INDIA FOR THE YEAR 1945 INCLUDING THE THIRTY-SECOND ANNUAL REPORT OF THE WOMEN'S MEDICAL SERVICE FOR INDIA. PRINTED BY THE MANAGER, GOVERNMENT OF INDIA PRESS, NEW DELHI

The report covers the activities of the following units :—

- (a) The original Countess of Dufferin's Fund.
- (b) The Women's Medical Service.
- (c) The Central Office.

The shortage of nurses both trained and under training continued to be acute. The action of the Government of India in sending nurses overseas for post-graduate training in Hospital Administration, Sister Tutor Course and Public Health will to some extent relieve the situation when they return. There are six post-graduate scholarships for these courses, two from the Central Government and four from the Provinces. Thirty-two scholarships have been sanctioned to enable suitable graduates and undergraduates to take four years' training in nursing in the United Kingdom. The introduction of the degree of B.Sc. Nursing by the University of Madras and the inauguration of this course at the Mission Medical College Hospital, Vellore, are a distinct step forward.

The paucity of trained women dispensers and compounders and trainees has also adversely affected the efficiency of our hospitals.

Three women doctors selected for training in Public Health will be sent overseas as soon as travel conditions permit.

THE COUNTESS OF DUFFERIN'S FUND AND THE WOMEN'S MEDICAL SERVICE

Countess of Dufferin's Fund.—Of the recurring income of Rs. 37,241 of the Fund Rs. 6,945 was spent on scholarships and prizes, Rs. 26,801 on grants to Provincial Dufferin Committees and hospitals for improvements. The Gilchrist Trustees, London, have been most generous in continuing their grant of £150 per annum for six scholarships at the Lady Hardinge Medical College.

The Council has 24 scholarships for award to women in the various medical colleges in Delhi, Madras, Bombay, Calcutta, Lahore, Lucknow, Agra, Patna, Cuttack and Vizagapatam. There were 1,273 women undergraduates in these colleges in 1945.

Women's Medical Service.—The work has steadily increased in all the hospitals in spite of trying conditions due to shortage of staff, drugs and finances.

Recruitment continued to be difficult owing to the demands of the army.

CENTRAL OFFICE

The Secretary as inspecting officer for the Women's Medical Service visited during the year all the hospitals under W.M.S. officers including the Lady Hardinge Medical College and Hospital. She also contacted women I.M.S. and I.A.M.C. officers in her capacity as Assistant Director-General, Women's Branch of the I.M.S. It is encouraging to note that in all these hospitals every attempt is being made to improve the out-patient departments and so bring them more into line with the modern conception of such a department, as a consulting, diagnostic and educative centre.

The rest of the report is devoted to accounts of the work done in various branches and hospitals under the fund.

R. N. C.

Correspondence

INFANTILE DIARRHOEA

SIR,—Bearing in mind the dearth of literature on one very important branch of Tropical Medicine, viz. children's disease in tropics, I would request you to try to arrange a series of articles on diarrhoea in infants in India.

My own impression is that hundreds of young infants must die annually from this cause alone in Bengal.

Yours, etc.,

M. MASWOOD KHAN,
MAJOR, M.B., B.S.

CHITTAGONG.

[Papers on the subject will be welcome.—Editor, I.M.G.]

PENICILLIN ADMINISTRATION

SIR,—I have read with interest the questions on 'Storage and Use of Penicillin' preferred by Dr. J. C. Bhattacharjee and the answers from your end published in July 1947 issue of the *Gazette*. I feel a particular concern for the 4th item of the questions and would like to say a few words in so far as my experiences are concerned. I hope you will please give it a publicity in your esteemed journal.

The use of penicillin at three-hourly intervals is not only a problem to the clinician but gravely affects the patient. Comparatively large doses (say 300,000 units in 1 c.c.) can of course be administered by the use of penicillin in wax and oil. It is however doubtful if a single injection of penicillin in wax and oil can be depended upon in the control of acute cases. In fact with the delayed absorption, penicillin in wax and oil can never attain a concentration in acute cases lethal to the penicillin susceptible organisms. I, of course, do not dispute the total unit content per cubic centimetre of wax and oil penicillin and I think 300,000 units in 24 hours is fairly sufficient. As a solution to the disadvantage of three-hourly administration and to suit the convenience of both myself and the patient, I started using about a year ago 100,000 units in watery solution three times a day intramuscularly (early morning, noon and the first part of the night). With the evidence of control of the infective process the three administrations were reduced to two (morning and night) and ultimately to a single morning injection before final withdrawal. I have employed this scheme of treatment in twelve of my cases comprising follicular tonsillitis, lobar pneumonia and a single case of acute gonorrhoea. In the first two groups, ten to twelve hundred thousand units were on an average necessary to effect a cure. In the gonorrhoea case (a male) however a total of 24 hundred thousand units were administered to leave the patient as clinically cured. I have now adopted this method of administration as a routine.

Since adopting the above scheme of penicillin administration I have gone through an abstract of discussions (the *Lancet*, 13th September, 1947, p. 397) on penicillin and streptomycin and I find to my satisfaction that Sir Alexander Fleming advocates the injection of very large doses of a watery solution as an alternative to the penicillin in wax and oil.

Yours faithfully,

A. C. DEY, L.M.F.,
Formerly Senior Resident
Medical Officer, Ashtanga
Ayurveda Hospital, Calcutta.

MEPACRINE PSYCHOSIS

SIR.—It does not seem that a full case has been made against mepacrine by Drs. M. S. H. Mody and Nandi writing about mepacrine psychosis in your issue of May 1947, pages 273-274. It is not said whether their cases were clinical or proven by an examination of the blood-films. It would also be necessary to exclude meningitis by making a lumbar puncture before they can dub mepacrine as the causative agent for the psychosis referred to by them.

It is a well-known fact that mepacrine is a slowly acting parasiticide. The doses recommended by the army for the routine use in malaria is 2 tablets t.d.s. for 3 days and one tablet t.d.s. for 4 days for adults—children receiving proportionate doses. Several lakhs of cases were treated on these lines in the army and no definite case of mepacrine psychosis was reported.

We had a few cases with identical symptoms as described by the writers in our patients while on mepacrine treatment. We found that quinine bishydrochloride gr. v given intravenously once or twice at most cleared the symptoms. We did not stop the oral mepacrine in any case. This would show that 'the psychosis' is a phenomenon of the disease itself and not due to the mepacrine.

Yours, etc.,
V. G. DESAI.

RIOT SURGERY

SIR.—The statement made by Dr. A. K. Basu in his article 'Experience of Riot Surgery' (*I.M.G.*, August 1947, p. 465) that 'shock for some reasons is conspicuously absent in these cases in the first few hours (Som and Mukherjee, 1947). In my experience this is dangerous teaching', is utterly untrue and misleading.

We never said that shock was conspicuously absent in all cases. We said in summary that 'shock in stab wounds was not usually marked'. We also said 'shock was not so marked and constant feature in uncomplicated abdominal cases (unlike what obtains in gun-shot wound of the abdomen)'. We pointed out in table I that out of 25 cases one had severe shock, seven had moderate shock, twelve had mild shock and five had no shock. This was estimated from blood pressure and pulse rate, not from mere guess work. Dr. Basu did not give any statistics of his patients. Moreover, when we discussed shock, we made a comparative statement of stab wound abdomen with that of gun-shot wound abdomen. In gun-shot wound abdomen shock was usually marked. In table III we pointed out that three cases of gun-shot wound abdomen died before operation. The reasons for marked absence of shock were given—like quick transport, absence of laceration of tissues, absence or insignificant gastro-intestinal spillage. Shock was proportional to the amount of hæmorrhage and severity of intra-abdominal visceral damage.

Dr. Basu stressed on resuscitation treatment before operation. We did resuscitation in cases indicated. We said that we used plasma or serum and saline before operation and even we did autotransfusion during operation in suitable cases.

In view of these facts there was no need for Dr. Basu to sit on judgment over other teachers. Incidentally, a casual and uncritical reader can be very 'dangerous' indeed.

Yours, etc.,
ASITA LAL SOM
and

MURARI MOHAN MUKHERJEE.

CAMPBELL MEDICAL SCHOOL
AND HOSPITAL, CALCUTTA.

Service Notes

ÆTIOLOGY OF APPENDICITIS

AN EXPERIMENTAL OBSERVATION

By R. NIGAM, M.D., M.S. (Hons.) (Luck.),
F.R.C.S. (Eng.)

Medical College, Lucknow

[This paper is a brief summary of part of a thesis submitted for the degree of M.D. (Pathology), Lucknow University.]

Introduction

APPENDICITIS is one of the commonest and not infrequently one of the most dangerous of the surgical emergencies and there is a good deal of evidence that mild attacks of inflammation of the appendix occur much more frequently than is generally supposed. Our knowledge of the exact pathology and ætiology of the disease is, however, far from complete.

Although appendicitis had been reported in the eighteenth century it received no proper recognition until 1886, when Fitz of Boston described a long series of cases, distinguished it clearly as the commonest cause of perityphlitis and gave it the name now universally adopted. Within twenty years it had attained the position of being the most common of all acute abdominal illnesses. This rapidly increasing menace in the beginning of the present century naturally drew the attention of both the pathologists and clinicians, and vague and fantastic explanations were given. Most of the evidence was clinical and co-incidental. Racial and climatic factors were blamed. The rôle of meat diet with a reduction of cellulose appeared to be a very plausible explanation to the older pathologists for the greater prevalence of the disease in the West and comparative rarity in the more vegetarian East. In fact the earliest experimental work of Wilkie (1914) on cats gave support to this hypothesis. Constipation has been looked upon with suspicion. The abnormal deformities of the appendix such as kinks and twists appeared to play a significant part in the ætiology. Various intestinal parasites, particularly *Oxyuris vermicularis*, have had many advocates in the genesis of appendicular disease.

Early in the twentieth century, with increasing interest in bacteriology, the infective theory in the causation of appendicitis was brought forward, there being two schools of thought—the hæmatogenous and enterogenous. Rosenow (1915) the pioneer of the hæmatogenous theory put forward the view that acute appendicitis was the result of the selective affinity of certain throat streptococci for the appendix. Poynton and Paine (1911) and Adrian (1901) working on the rabbit came to a similar conclusion.

McMeans (1917) and more recently Williams and McLachlan (1930) however have shown that the concentration of bacterial emulsion necessary to produce lesions in the appendix was far too much to occur naturally in human beings. Patey and Whitby (1933) working on the pathology of cholecystitis found no experimental evidence to support Rosenow's theory of elective localization.

Aschoff (1932) on the other hand, by extensive studies of normal and inflamed human appendices, showed that the appendix has a special bacterial flora, the members of which are responsible for the attack; he suggested that in acute appendicitis there is an enhanced virulence of this normal flora brought about probably by stagnation of fæces within it.

Lansdown and Williams (1915) after a histological survey of inflamed appendices came to the conclusion that it was the lymph follicles in the submucosa which were the primary seat of disease in the appendix, and not the mucous membrane, thus lending support to the hæmatogenous theory. Aschoff, however, will have none of it. He has always held that appendicitis is an enterogenous infection arising on the surface of the mucosa and denies the possibility that the disease may ever be blood-borne.

Wangensteen (1937) and his co-workers have investigated the function of the human organ in appendicostomy cases and have stressed mechanical causes as responsible agents in the genesis of inflammations in the vermiform appendix.

A more recent paper on the ætiology of appendicitis is that of Wells (1937) from the Dunn School of Pathology, Oxford. From his work on animals Wells supports the enterogenous origin of the disease.

The present paper contains the experimental part of a thesis on the pathogenesis of appendicitis which was conducted both on clinical and experimental bases.

Experimental work

Observations were made on fifty adult rabbits. The rabbit is the only easily available laboratory animal which has an appendix at all comparable, both in microscopical structure and naked-eye appearance, with that of man. Also appendicitis occurring spontaneously in rabbits has been reported in the literature (Mori, as quoted by Wells, 1937). These were the main reasons for choice of the rabbit in the present investigation.

Experiments were planned to observe the changes produced in the appendices of rabbits under the following conditions:—

(a) Ligation of the root of the appendix by a silk thread avoiding the blood supply of the viscus.

(b) Ligation of the root of the appendix including the appendicular artery and vein in the ligature.

(c) Ligation of the root of the appendix and obstruction of the venous return by ligature of the appendicular vein.

Fig. 1.—Normal appendix of rabbit *in situ*.
(a) Appendix (3 to 4 inches). (b) Cecum.
(c) Terminal ileum. (d) Colon.

Fig. 2.

viscus, the point of entry being subsequently sutured by catgut.

(f) Traumatization of mucous membrane followed by introduction of a living emulsion of streptococci into the lumen by a needle passed through the tip.

(g) Introduction of a foreign body in the form of glass beads or large fruit seeds into the lumen of the appendix to observe the effect of intraluminal obstruction. These were introduced into the lumen by incising the root of the appendix and suturing the wall subsequent to the introduction by catgut.

(h) Daily intravenous injections of emulsions of virulent streptococci isolated from the throat of patients suffering from acute tonsillitis. These injections were given daily into the marginal ear vein of the rabbit over a period of 3 to 4 weeks, unless the animal died earlier, after which the appendix was removed for histological examination.

The concentration of the bacterial suspension was estimated by the comparative opacity tube method. The doses varied between 200 and 600 millions/c.c.

Hæmolytic streptococci and *Str. viridans* were employed.

(i) Observations as under (h) in animals with appendices which had been traumatized.

Operations exposing the appendix were done with aseptic precautions and under local procaine* infiltration anaesthesia. The abdominal

after the operations surprisingly well and operative mortality was very low. Except for two animals which developed a ventral hernia

weeks to a month the appendix was removed for histological examinations, unless the animal had died already of acute appendicular inflammation

Fig. 4.

Fig. 5.

the others fared very well. Special procedures adopted in some experiments have been men-

and peritonitis. A post-mortem examination was done on the animals which died.

Observations

(a) Complete obstruction of the lumen of the appendix plays the most significant rôle in the causation of acute appendicitis. The obstruction may be either by a simple ligature of the root of the appendix or by a large foreign body introduced into its lumen. All the animals died of acute appendicitis (figures 2, 3, 4 and 5).

Fig. 6.—Partial obstruction of the appendix, no inflammation. (a) Probe shows patency of lumen. (b) Ligature site.

Fig. 7.—Root of appendix (figure 6) viewed end on. (a) Ligatured part. (b) Semilunar patent lumen.

tioned already. The rectal temperature of the animals was recorded and after a period of three

(b) If the obstruction of the lumen was partial, in spite of a similar degree of trauma produced by the ligature, as in animals with complete obstruction of the lumen of the appendix, no inflammation followed (figures 6 and 7).

(c) Almost all the animals with complete ligature or obstruction showed a rising rectal temperature (104 to 105°F.).

Another significant feature observed was that all these animals developed diarrhoea before death.

(d) Trauma to the mucous membrane is not an essential factor in the genesis of acute

(h) Intravenous injections of living emulsions (100 to 600 millions) daily for over 30 days of the same bacteria, in normal rabbits, or those with local trauma to the appendix produce no inflammation in that viscus. The rabbit appears to be immune to these organisms. Except for a rise in temperature no other abnormality was observed.

Fig. 8.

Mucocoele of the appendix ('X'—site of ligature of root and appendicular vein).

Fig. 9.

appendicitis in addition to obstruction. All my experimental animals with ligature (complete obstruction without trauma to mucous membrane) developed acute appendicitis. I am not in agreement with the statement of Wells (1937) that trauma and obstruction produce appendicitis while obstruction alone produces a mucocoele.

(e) A mucocoele or more exactly pyocoele of the appendix developed in those animals only in which there was a ligature of the lumen of the appendix and an associated obstruction of the venous return produced by ligature of the appendicular vein. The element of vascular stasis in the appendix in addition to complete obstruction of the lumen is necessary for the development of a mucocoele (figures 8 and 9).

(f) Abnormal kinks or twists of the appendix cause no inflammation (figure 10).

(g) Trauma to the mucous membrane of the appendix by itself or with intraluminal introduction of living emulsions of *Str. hemolyticus* or *Str. viridans*. (Doses 1,500 to 2,000 millions/c.c. from the throats of patients suffering from acute tonsillitis produce no inflammation in the rabbit's appendix.)

(i) The rabbit's appendix possesses an active peristaltic movement capable of expelling small

Fig. 10.—Kinked appendix.

foreign bodies into the cæcum. All animals in whom the foreign body was large enough to

produce complete obstruction developed acute appendicitis (figure 11).

(j) Histological examination of the rabbit's normal appendix shows that it resembles the human appendix except for the following histological differences (figures 12 and 13, plate XXVIII):—

1. There is no well defined muscularis mucosæ coat.

2. The submucosa consists of a diffuse mass of lymphoid tissue without the formation of isolated lymph follicles as in the human appendix.

3. The muscle coat is a very thin layer.

(k) Histology of diseased rabbit's appendix resembled that of human appendicitis in the following details:—

Fig. 11.—All four glass beads were passed out of the appendix lumen.

1. Necrosis of mucous membrane, atrophy of lymphoid tissue in the submucosa, and formation of a thick inflammatory exudate involving the muscle and serous coats (figures 14, 15, 16 and 17, plate XXVIII).

2. Localized crushed trauma to the appendix produces a histological picture indistinguishable from chronic appendicitis in human beings (figures 18, 19, 20, 21, 22 and 23, plate XXIX).

(l) The bacterial flora of the rabbit's appendix is similar to the flora in the human appendix. The following organisms were found on culture: *Ps. pyocyaneus*, *B. coli*, *B. subtilis*, and *Clastridium* group.

(m) I have come to believe that in the genesis of acute appendicitis obstruction is the all important factor, and that the enterogenous organisms of the appendix are the ones that set up inflammation.

(n) Although the genesis of acute appendicitis is apparent the cause of chronic appendicitis is still obscure.

Discussion

My observations, to some extent similar to those of Wells in support of the enterogenous origin of acute appendicitis as a result of obstruction, are as follows:—

1. I agree with his conclusion that, in the rabbit, injection of living bacteria, damage to the mucosa, partial cutting off of the blood supply, or partial obstruction of the lumen alone have no effect on the appendix.

2. He mentions that obstruction of the lumen of the appendix by a foreign body has no effect on the appendix. This may be true for small foreign bodies about $\frac{1}{4}$ inch in diameter but all the animals in which I introduced larger bodies, i.e., over $\frac{1}{2}$ inch diameter, developed acute appendicitis with a mortality of 100 per cent.

3. Wells refers to the fact that ligature of the appendicular artery and vein and mesoappendix produces gangrene in the rabbit's appendix but this was not observed by me. There is such a profuse anastomosis among the vessels of the ileum, ascending colon and the appendix that the mere ligature of the appendicular vessels and mesoappendix is not sufficient to produce gangrene. The element of vascular occlusion was experimented on to test the ingenious hypothesis put forward by G. Ricker who advocated that appendicitis is primarily due to vascular disturbances of the organ brought about by reflex irritation of their nerves, a process akin to the 'chill' mechanism of respiratory disorders. In severe cases Ricker contended that the vascular disturbance is sufficiently intense to cause necrosis or infarction of the tissues which then become invaded by microbes from the lumen. This hypothesis as quoted by Aschoff (1932) in his book on appendicitis finds no support from my experimental results. Ligature of the vessels also includes the perivascular sympathetic nerve plexuses but in none of the animals was there any pathological response observed in the appendix. Aschoff himself, however, disagrees with such a hypothesis. He denies that a vascular disturbance is the primary lesion. He believes that such changes are secondary to a bacterial invasion of the surface of the mucosa.

4. Wells states that simple ligature of the root of the appendix produces mucocele of the appendix, and acute appendicitis follows only when the mucosa is traumatized either by crushing or scratching with a sharp needle in an appendix whose lumen has been occluded. For acute appendicitis to develop Wells emphasizes two elements, obstruction and break in mucosal barrier. My experimental results however do not agree with Wells' conclusions. I found that simple ligature of the root of the appendix alone caused acute appendicitis in 100 per cent of the animals. The factor of trauma to mucous membrane was unnecessary. I thought that a ligature may by itself damage the mucosa; and so in a set of animals I tied

the ligature very gently, but in these too the result was acute appendicitis and not mucocele.

5. I however found that of those animals whose appendix root had been ligatured, and the appendicular vessels had also been included in the ligature 60 per cent developed a distended appendix (mucocele). The contents were mucoid matter and pus cells (hence strictly speaking pyocele of appendix, a result of acute inflammation). Mucocele in the strict sense was not produced in any of the animals observed by me. Perhaps the ligature had produced obstruction only of the venous return leaving an intact arterial flow with a higher blood pressure and this caused congestion and increased secretion by the mucous glands. In order to prove this in a set of animals I tied the root of the appendix and carefully ligated the appendicular vein leaving the artery untied, and I found that the majority of these animals developed a distended appendix. Hence in my opinion the element of venous obstruction plus complete occlusion of appendix lumen is essential for the development of distended appendix resembling a mucocele. In my experiments I failed to produce giant mucoceles as stated by Wells or mucoceles in the true sense.

6. I agree with Wells that the hæmatogenous hypothesis advocated by Rosenow (1915) and by Poynton and Paine (1911) has no support from the experimental results on rabbit; at least by using doses of bacteria which would certainly be dangerous to the human subject. Extremely concentrated bacterial emulsions were not tried.

7. The hypothesis put forward by Wangenstein (1937) and his co-workers demonstrating the secretory function of the appendix is supported from my experimental results.

8. My experimental findings are in agreement with the enterogenous hypothesis advocated by Aschoff (1933) as far as the ætiology of acute appendicitis is concerned. The actual infection of the mucosa is, Aschoff holds, independent of any trauma; it occurs, for example, distal to and not in the immediate neighbourhood of a focus of obstruction. It seems to be due to an increase of virulence of the bacteria normally present in the lumen. How this increase of virulence is brought about is quite uncertain, but it depends largely on stagnation of contents. It may be pointed out here that Aschoff attributes stasis only as the all important factor and does not think that a break in mucosal barrier as contended by Wells to be necessary in the causation of acute appendicitis.

The ætiology of chronic appendicitis is still obscure. I have been unable to produce this experimentally and the literature on this subject is also very scanty. Whether this is due to enterogenous infection, or of hæmatogenous origin, one cannot say with conviction. It is this aspect of the disease that shakes the

foundations of both the ardent enterogenous and rather out of date hæmatogenous schools.

Summary

1. A brief review of the various hypotheses about the ætiology of appendicitis is given.

2. Experimental observations were made on fifty young adult rabbits. The main experimental findings with illustrations are given.

3. There was no evidence found to support the hæmatogenous origin of acute appendicitis.

4. Acute appendicitis is undoubtedly due to complete obstruction of the lumen of the appendix either by a constricting ligature or large foreign body. Mucosal damage is not a necessary factor.

5. The organisms cultured from diseased appendices of rabbits were similar to those of normal appendices showing that infection is intrinsic in origin.

6. A histological picture identical to chronic appendicitis in the human being was produced by a crushing trauma to the appendix localized only to the site of injury.

7. Unusual bends or twists of the appendix, repeated daily intravenous or intraluminal injections, of living and virulent streptococci, over a duration of a month in some instances, produced no gross or microscopic lesions confined to the appendix. The rabbit appears to be quite immune to hæmolytic streptococci isolated from the throats of patients suffering from an acute streptococcal infection.

8. Although the ætiology of acute appendicitis is proved to be obstruction, the ætiology of chronic appendicitis is still uncertain.

HISTOPATHOLOGICAL CHANGES IN LIVER IN CONGESTIVE HEART FAILURE

(STUDY BY NEEDLE BIOPSY)

By P. N. WAHI, M.D., M.R.C.P.

(Professor of Pathology, Medical College, Agra) and

K. S. MATHUR, M.D., M.R.C.P.

(Physician, Thomason Hospital, Physician In-charge, Heart Clinic, and Lecturer in Cardiology, Medical College, Agra)

THE usual textbook description of the changes produced in the liver in chronic venous congestion, the so-called nutmeg liver, are based on the post-mortem findings which obviously could not depict an early picture. The purpose of the present investigations was to study the histopathological changes produced in the liver in ward patients showing various grades of congestive heart failure.

Mallory (1911) demonstrated focal hæmorrhagic necrosis in many livers with severe passive engorgement. Lambert and Allison (1916) in their review of 112 cases from literature, in which chronic venous congestion of the liver was most marked, described in detail many variants from the usual histological picture. Some of their cases showed fatty changes rendering the centre of the lobule yellow with a surrounding red ring as a result of hyperæmia. Other cases showed regeneration of liver cells in the periphery of the lobules. A few cases were conspicuous by changes in the reticular and collagenous skeleton. Eppinger (1920) found bile thrombi in the bile ducts of some of his cases. Boland and Willius (1938) described three general groups of histopathological changes in cardiac livers.

Katzin, Waller and Blumgart (1939) found that in 286 cases, in which death was due to heart failure, the incidence of hepatic fibrosis was three times as great as in 1,714 control necropsies. The incidence and severity of fibrosis increased with the duration of right heart failure. Garvin

(1943) observed 35 cases of cardiac cirrhosis among 790 autopsied patients in whom heart disease was the chief cause of death; while Koletsky and Branebee (1944) reviewed 4,200 autopsies and found 30 such cases for their study. In both these studies cardiac cirrhosis occurred essentially in patients with rheumatic heart disease. It was less frequent in hypertensive patients and rare in other ætiological forms of heart disease except chronic constrictive pericarditis. Both authors came to the conclusion that repeated episodes of decompensation favour the development of the lesion.

Costero and Moguel (1947) in a paper read before the second Inter-American Congress of Cardiology have described the histological changes in the liver during congestive heart failure passing through the following stages:— (a) congestion of the central venules with intense anoxia of the reticular endothelium forming the wall of sinusoidal blood capillaries; (b) hyperplasia of the reticular endothelium forming the wall of sinusoidal blood capillaries; (c) elaboration of precollagenous fibres by this hyperplastic reticular endothelium; (d) intense compression of the trabeculæ through spontaneous retraction of the recently formed fibres with collapse of the intratrabecular bile capillaries and compression atrophy of the liver cells; (e) fragmentation of the trabeculæ into isolated cells; (f) reabsorption of the isolated atrophic cells.

Needle Biopsy of the Liver

The twelve cases selected for the present study were carefully prepared for the needle biopsy of the liver in view of the profuse bleeding from the site of the puncture in chronic venous congestion reported by Hoffbauer (1947). The bleeding, coagulation and prothrombin times of each patient were determined and Kapilin 5 mg. intramuscular injections were given the previous evening and on the morning of the biopsy as a routine. The danger of the symptoms of acute heart failure supervening after the biopsy was realized during the initial part of the investigations; thereafter it was made a rule not to undertake the biopsy unless the patient was completely digitalized. The details of the preparation of the patient, puncture of the liver and after care have been described by Wahi (1946). Vim Silverman needle was used for liver biopsy.

The details of the histological findings along with very brief case reports are given below:—

Case Reports with Histological Findings of Biopsy Tissue

Case 1.—R. P., 50 years, Hindu female, on admission to hospital complained of cough, duration 5 years; shortness of breath, duration 1 year; and cedema of feet, legs and abdomen, duration 1 month. She was diagnosed 'Chronic bronchitis and emphysema with congestive heart failure'. She gave a history of two previous

attacks of congestive failure. Liver enlarged 3 inches. Hippuric acid 0.45 gm.

Histological examination of the liver tissue obtained by biopsy showed the dilated central veins. The sinusoids around most of these were dilated. Liver cells in between the dilated capillaries were compressed and atrophied. Most of the liver cells especially in the midzonal areas showed an extensive cloudy swelling. At a number of places liver cells showed complete necrosis and replacement fibrosis. Hæmorrhages were present due to overwhelming distension of capillaries with venous blood, their rupture and escape of that blood in the intercapillary spaces formerly occupied by the liver cells. At one place there was extensive deposit of bile pigment.

Case 2.—S., 14 years, Hindu male, was admitted to hospital complaining of breathlessness, puffy face, discomfort in abdomen, loss of appetite, vomiting, exhaustion and heavy head, duration 1 month. He was diagnosed 'Rheumatic mitral stenosis and regurgitation with congestive failure'. No previous history of cardiac failure. Liver enlarged 5 inches. Hippuric acid 0.16 gm.

Histological examination of the biopsy tissue showed the most extensive cloudy swelling and fatty degeneration of the liver cells met with in this series. The capillaries did not show much dilatation (figure 2, plate XXX).

Case 3.—R. S., 17 years, Hindu male, on admission complained of breathlessness and cough, duration 2 months; generalized œdema, pain abdomen and loss of appetite, duration 1 month. He was diagnosed 'Rheumatic mitral stenosis and aortic incompetence with cardiac failure'. No previous history of failure. Liver 5 inches enlarged. Hippuric acid 0.30 gm.

Histological examination showed dilatation of sinusoids, cloudy swelling and at places necrosis of liver cells. Blood pigments were present.

Case 4.—K., 22 years, Hindu female, complained of breathlessness, cough and swelling, duration 5 months. She was diagnosed 'Rheumatic mitral stenosis and aortic incompetence with cardiac failure'. No previous history of heart failure. Liver 6 inches enlarged. Hippuric acid 0.54 gm.

Histological examination showed marked dilatation of sinusoids, hæmorrhages, cloudy swelling of midzonal cells and patches of cellular infiltration cells being mostly lymphocytes and fibrocytes (figure 4, plate XXX).

Case 5.—B., 16 years, Hindu male, on admission complained of breathlessness, cough and œdema, duration 1 month. He was diagnosed 'Rheumatic mitral stenosis and aortic incompetence with cardiac failure'. During the last one year he had three previous attacks of congestive heart failure when he was laid up in bed for about a month each time. Liver just palpable. Hippuric acid 0.44 gm.

Histological examination showed dilatation of sinusoids, atrophy of cells surrounding the

hepatic vein, cloudy swelling and fatty degeneration of midzonal liver cells and patches of necrosis. Deposit of biliary pigment was present.

Case 6.—M., 25 years, Hindu female, on admission complained of breathlessness, cough and œdema, duration 6 months. She was diagnosed 'Rheumatic mitral stenosis and regurgitation with congestive heart failure'. The patient had six pregnancies. The first two were uneventful. During the later part of third, fourth and fifth pregnancies she suffered from mild attacks of cardiac failure but they cleared up soon after childbirth each time. During the sixth pregnancy the symptoms appeared from the fourth month and had continued since even after puerperium. Liver 5 inches enlarged. Hippuric acid 0.12 gm.

Histological examination showed marked dilatation of sinusoids, cloudy swelling and atrophy of liver cells (figure 1, plate XXX). There were patches of fibrosis (figure 6, plate XXXI).

Case 7.—P., 40 years, Hindu male; on admission complained of breathlessness, duration 2 months; fainting attacks, duration 1 month, and swelling feet and abdomen, duration 7 days. He was diagnosed 'Primary benign hypertension and atherosclerotic aortic stenosis and incompetence with cardiac failure'. No previous history of heart failure. Liver 2 inches enlarged. Hippuric acid 0.42 gm.

Histological examination of the biopsy tissue showed marked dilatation of sinusoids with cloudy swelling of liver cells. Hæmorrhages could be seen at places. Patches of cellular infiltration were present (figure 5, plate XXXI).

Case 8.—M., 40 years, Hindu female, on admission complained of breathlessness, palpitation and cough with expectoration, duration 18 months. She was diagnosed 'Rheumatic mitral stenosis with auricular fibrillation and congestive heart failure'. She gave a history of one previous attack of failure. Liver just palpable. Hippuric acid 0.64 gm.

Histological examination revealed marked dilatation of sinusoids and atrophy of liver cells. Liver cells showed cloudy swelling with fatty degeneration at many places. Diffuse biliary pigment was present. Patches of cellular infiltration were seen at several places.

Case 9.—R. L., 52 years, Hindu male, on admission complained of cough with expectoration, duration several years; and breathlessness, palpitation and swelling of feet, duration 2 months. He was diagnosed 'Pulmonary tuberculosis, with marked fibrosis and cavitation with congestive heart failure'. He gave a history of one attack of failure 9 months previous to admission. Liver enlarged 2 inches. Hippuric acid 0.55 gm.

Histological examination showed dilatation of sinusoids, atrophy of liver cells, patches of necrosis; patches of cellular infiltration and fibrosis (figure 7, plate XXXI). In some areas

liver cells were swollen, cytoplasm was granular and nucleus pushed to one side. At other places only skeleton of liver cells remained behind and the field was occupied by dilated sinusoids.

Case 10.—M., 30 years, Mohammedan male, on admission complained of breathlessness, general weakness and lack of appetite, duration 1 year; and oedema over face and feet, duration 6 months. He was diagnosed 'Rheumatic mitral stenosis with cardiac failure'. No previous history of failure. Liver enlarged 3 inches. Hippuric acid 0.52 gm.

Histological examination showed dilatation of sinusoids and extensive cloudy swelling. Cellular infiltration was present. Patches of necrosis and definite fibrosis present (figure 8, plate XXXI).

Case 11.—B., 50 years, Hindu male, on admission complained of cough with expectoration, duration 5 years; breathlessness, oedema and abdominal discomfort, duration 1 month. He was diagnosed 'Chronic bronchitis and emphysema with heart failure'. He had twice during the previous years developed the same group of symptoms. Liver 4 inches enlarged. Hippuric acid 0.32 gm.

Histological examination showed dilatation of sinusoids and cloudy swelling.

Case 12.—P., 44 years, Hindu male, on admission complained of breathlessness and oedema, duration 4 months. He was diagnosed 'Chronic bronchitis and emphysema with cardiac failure'. Apart from cough he had kept fairly well in the past. Liver 3 inches enlarged. Hippuric acid 0.28 gm.

Histological examination of the liver tissue obtained by biopsy showed extensive cloudy swelling (figure 3, plate XXX), patches of necrosis and fibroblastic reaction.

Observations and Comments.

According to the histopathological observations these cases may be grouped into four types:—

Type I.—Dilatation of sinusoids with cloudy swelling of liver cells and hæmorrhages due to rupture of distended capillaries (figure 1). These are the earliest changes in passive congestion of the liver. They are invariably found in all cases either alone or in conjunction with other microscopic changes to be described later. The atrophy of liver cells is found adjacent to the central vein of hepatic lobules while the cloudy swelling is much more marked in the areas close to them. Hæmorrhages found in these cases are due to overwhelming distension of capillaries with venous blood, their rupture and escape of that blood in the intercapillary spaces formerly occupied by the liver cells.

Type II.—Liver cells showing extensive cloudy swelling and fatty degeneration with or without much dilatation of sinusoids (figures 2 and 3). Anoxæmia is so advanced in case 2, which

belonged to this group, that almost all liver cells show the degenerative changes and are cut out of action to a very marked degree.

Type III.—Patchy necrosis of liver cells with or without cellular infiltration (figures 4 and 5). The necrosis is most marked in the central third of the hepatic lobules. Sometimes the necrosis is superimposed on the atrophic cells of the central portion of the lobule. The necrosis is usually patchy. Patches of cellular infiltration, when present, are made up of lymphocytes and fibrocytes chiefly.

Type IV.—Fibrotic changes (figures 6, 7 and 8). Fibrotic changes met with in cases 1, 6, 9 and 10 are all patchy. The fibrosis is usually present in the degenerated areas associated with necrosis. The series is too small to draw conclusions as to the relation of fibrosis to the number of attacks of congestive failure or their ætiology but it is evident that the fibrosis depends on the repeated episodes of cardiac failure with periods of partial and complete restoration of cardiac function.

The four types described above correspond with the three general groups of Boland and Willius (1938) and five groups of Lambert and Allison (1916). Absence of typical cardiac cirrhosis in the present series is due partly to small number of cases and partly to short duration of illness, with not more than four attacks of decompensation before admission. On account of lack of treatment facilities, the hospital class of patients do not survive the first few attacks of decompensation at the most and by then typical cardiac cirrhosis is not developed.

No definite correlation has been established between the histological findings and the values of hippuric acid excretion. The detailed study of the hippuric acid excretion in liver conditions in congestive heart failure will form the basis of another paper.

Summary.

Twelve cases of congestive heart failure have been described on whom the needle biopsy of the livers by Vim Silverman needle was done.

From the histopathological study of the biopsy tissue four types of hepatic changes have been described in congestive heart failure.

Type I.—Dilatation of sinusoids with cloudy swelling of liver cells and hæmorrhages.

Type II.—Liver cells showing extensive cloudy swelling of liver cells and fatty degeneration with or without much dilatation of sinusoids.

Type III.—Patchy necrosis of liver cells with or without cellular infiltration.

Type IV.—Patchy fibrosis.

CLINICAL SIGNIFICANCE OF
HYPOPROTEINÆMIA

By N. C. DATTA

Department of Physiology, Grant Medical College,
Bombay

MEASUREMENTS of plasma proteins were made in the beginning of the nineteenth century. Nevertheless, clinical observations were first stimulated by the work of Salvesen (1929) in Sweden. The significance of these important studies was overlooked for many years. It is only recently that the plasma proteins have achieved considerable clinical significance. Butt and co-workers (1939) have reported important studies on the subject. Myers and Muntwyler (1940) have written a brief summary of the few outstanding contributions which have found practical application in clinical work. Important contributions on the significance of the plasma proteins have been made by Peters (1942) and by Kagan (1943). The most recent discussion on the subject is by Muntwyler and Brooklyn (1945). This review will emphasize the clinical significance of hypoproteinæmia and will merely outline a few theoretical considerations dealing with the occurrence of hypoproteinæmia and its common clinical manifestations.

HYPOPROTEINÆMIA

Its occurrence and clinical manifestations

An abnormal lowering of plasma protein has a wide clinical significance and may occur as a result of (1) malnutrition, (2) excessive loss of nitrogen, (3) loss of plasma proteins, and (4) a defect in protein synthesis.

Malnutrition.—Hypoproteinæmia due to malnutrition is undoubtedly the one most prevalent in India and occurs in those who are unable to eat sufficient protein for economic reasons. It may also be present in those who are unable to assimilate food due to intrinsic gut changes. The albumin fraction is the one significantly involved in malnutrition. Weech (1938) and Elman and co-workers (1942) have shown

very clearly that the fall in plasma albumin begins promptly on withdrawal of protein from the diet. The longer the protein is withdrawn, the more is the hypoproteinæmia.

Excessive loss of nitrogen.—Loss of body weight may not indicate in a quantitative measure the degree of tissue protein loss because the changes in the water content are frequent and introduce a complicating factor. Loss of tissue protein is capable of clinical measurement by the amount of nitrogen excreted in the urine, in as much as all tissue protein, when broken down, results in a terminal excretion of nitrogen largely as urea and ammonia. Normally a few grammes of nitrogen are excreted in the urine each day due to metabolic wear and tear.

Excessive destruction of tissue protein occurs in wasting diseases and also in various infections as is revealed by the loss of nitrogen in the urine. Patients with severe cutaneous burns have also been found to excrete large amounts of nitrogen in the urine. Taylor and co-workers (1943) reported that, of 81 patients with burns, 40 had hypoproteinæmia. The degree of hypoproteinæmia seemed to have a definite correlation with the severity of burns.

Hypoproteinæmia in hyperthyroidism is due to excessive destruction of tissue protein as revealed by the increased loss of nitrogen in the urine.

Excessive loss of plasma protein.—Hypoproteinæmia occurs in renal conditions in which albuminuria is an important factor. Acute hæmorrhage is an excellent example of hypoproteinæmia produced by an extensive loss of plasma protein. Acute protein deficiencies are a feature of extensive burns following the exudation of serum in large traumatic areas. Blister fluid in burns is like plasma and may contain total protein varying from 3.7 to 4.3 g. per 100 c.c. Loss of protein is clearly an important and serious effect of severe cutaneous burns. It seems likely that many if not all the manifestations of severe burns are connected with this loss. The general manifestations of severe burns develop rapidly and if they are combated promptly many lives may be saved.

Defect in protein synthesis.—The intimate association of liver with the maintenance of normal level of plasma proteins is well known. Hypoproteinæmia has been found at one time or another in all patients who had chronic or advanced diseases of the liver. In cirrhosis of the liver with severe diffuse hepatic damage, hypoproteinæmia has been found to be more pronounced and results primarily from the inability of the liver to produce normal serum protein rather than to the external loss of protein in the ascitic fluid. There is a direct correlation between the level of serum albumin and the clinical course. Post and Patek (1942) reported the results of nitrogen balance studies which indicate that the patients with cirrhosis of the liver absorb and retain food protein. The evidence suggests that the mechanism of the synthesis of serum protein is impaired.

In accordance with the basic production mechanism of hypoproteinæmia Davis and Getzoff (1942) classified hypoproteinæmia into three types:—

1. Pre-hepatic hypoproteinæmia, in which there is interference with adequate intake, digestion or absorption of the plasma protein building material, but the ability of the liver to form plasma protein is not affected.

2. Hepatic hypoproteinæmia is primarily due to the inability of the liver itself to form plasma protein in spite of the fact that normal supplies of the protein building material are received from the intestine.

3. Post-hepatic hypoproteinæmia, in which there is adequate formation of plasma proteins by the liver, but an abnormal amount of plasma protein is lost as in severe burns, acute hæmorrhage or suppuration, etc.

CLINICAL MANIFESTATIONS OF HYPOPROTEINÆMIA

Œdema.—The association of hypoproteinæmia with œdema is well known. Nutritional œdema is probably one of the most important of the serious clinical manifestations of hypoproteinæmia. It is, however, important to realize that nutritional œdema is a late manifestation of hypoproteinæmia, for long before frank œdema appears, the adverse effect of hypoproteinæmia and incipient œdema are at work.

Barden, Radvin and Frazier (1937) showed by roentgen studies a marked delay in gastric emptying time in post-operative patients. The gastric emptying time varied inversely with the level of plasma proteins. The marked retardation of intestinal motility observed in dogs in which hypoproteinæmia has been produced has been attributed by Barden and co-workers to the œdema of the small intestine. Thompson, Radvin and Frank (1938) found that the delay in the intestinal motility was corrected following the restoration of the plasma proteins to normal level.

Ascites.—Although the accumulation of ascitic fluid in cirrhosis of the liver is largely due to portal obstruction, hypoalbuminæmia which is so frequent in these patients undoubtedly plays a part. On the other hand, it seems fairly certain that peripheral œdema, when it occurs in patients with cirrhosis, is determined largely by the protein deficiency. Elman and Lischer (1943) consider 'that the added and perhaps precipitating factor of increased portal pressure

explains why the accumulation of fluid in the peritoneal cavity is easier and more persistent than peripheral œdema'.

PLASMA PROTEINS IN NORMAL INDIVIDUALS

Literature contains several values of plasma proteins in normal individuals. These values are not wholly adequate since most of the studies have been made upon small groups of persons whose state of health in many cases is open to question. Besides, there is a great paucity of data with respect to plasma protein values in normal Indians.

This communication presents the summary of results of fractionation of plasma proteins in 70 healthy Indians by the sodium sulphate method of Howe (1921). All subjects with good health records were taken as normal.

Albumin.—The range of albumin was from 4.3 to 5.34, with a mean of 4.90 g. per 100 c.c. which is in good agreement with the mean of 5.06 g. reported by Gutman and co-workers (1941). The albumin values reported in the literature fall within a wider range from 3.66 to 5.7 g. per 100 c.c. In all probability, the concentration of albumin will not normally exceed 5.4 g., whilst values below 4.0 g. per 100 c.c. are definitely subnormal.

Total globulin.—The mean value of 2.59 g. per 100 c.c. for the total globulin is essentially the same as reported by Linder and co-workers (1924) and also by Salvesen (1926). Our mean is distinctly higher than the mean of 2.0 g. per 100 c.c. reported by Gutman. The spread of total globulin was from 2.15 to 2.93 g., with three-quarters of the values falling between 2.2 to 2.6 g. From the trend of our values in health and disease it would appear that all values above 2.8 g. per 100 c.c. are the result of disease process.

Euglobulin.—Only a small fraction of the total globulin is precipitated by 14.5 per cent sodium sulphate solution and is referred to as euglobulin. Our mean of 0.55 g. per 100 c.c. is higher than the mean of 0.39 g. reported by Stacey (1945), and distinctly higher than the mean of 0.2 g. reported by Gutman. In spite of the higher mean, most of the values fell well within the range of 0.18 to 0.6 g. per 100 c.c. reported by those workers.

Pseudoglobulin.—The range of pseudoglobulin was from 1.3 to 2.24 g. per 100 c.c., with a mean

TABLE I
Fractionation of plasma proteins in normal individuals

Average of	Total protein	Albumin	Globulin	Euglobulin	Pseudoglobulin	Fibrinogen
		g. per 100 c.c.				
45 males ..	7.51	4.93	2.58	0.52	1.82	0.25
25 females ..	7.49	4.87	2.60	0.56	1.74	0.26

of 1.79 g. which is in agreement with the mean of 1.8 g. reported by Gutman.

Fibrinogen.—The range of fibrinogen was from 0.12 to 0.48 g. per 100 c.c., with a mean of 0.25 g. which is the same as reported by Ham and Curtis (1938) in a review of plasma fibrinogen in normal persons.

Total protein.—The spread of total protein was from 7.0 to 7.95 g. per 100 c.c. This is in agreement with general experience.

PLASMA PROTEIN VALUES IN INDIVIDUALS APPARENTLY NORMAL

An alteration in the value of plasma protein may be encountered in individuals apparently normal. Both total protein and albumin below normal were found in persons apparently normal

out whether any departure from the normal could be associated with the presence of oedema of pregnancy toxæmias.

The total protein is low in pregnant women. Dieckmann (1941) reported that albumin alone suffers the fall, the globulin remains unchanged. According to him the low protein in pregnancy is due to dilution of blood. This appears incompatible since dilution will affect both the constituents. Our results indicate a definite increase in globulin during pregnancy. Total protein below 7 g., albumin below 4 g. and globulin above 3 g. per 100 c.c. were found in almost all the 40 cases of normal pregnancy. In toxic pregnancy the albumin is considerably lowered, the globulin showing little change from non-toxic group.

	Total protein	Albumin	Globulin	Eu-globulin	Pseudo-globulin	Fibrinogen
Average of 40 cases of normal pregnancy.	6.90	3.70	3.20	0.7-1	1.8-2.5	0.2-0.5

but under weight. It is likely that the protein reserves in these persons remain at a low level without any subjective or objective manifestations and is reflected in an accurate manner in a lowered range of plasma albumin.

Total globulin above normal (above 3 g. per 100 c.c.) was also found in persons susceptible to mild infections such as common cold, sore throat, etc., otherwise normal.

That an abnormality in the values of plasma proteins become apparent long before the disease is clinically perceptible is evident from the result of table II. All the subjects appeared normal when blood was collected for analysis.

PLASMA PROTEIN VALUES IN DISEASES PRESENTING HYPOPROTEINÆMIA

Hypoproteinaemia is undoubtedly due to a lowering of albumin, yet for the sake of study the cases can be classified under two heads :

1. Cases in which hypoproteinaemia is associated with a lowering of albumin, the globulin remaining unchanged.

2. Cases in which hypoproteinaemia is regularly associated with an increase in the value of globulin.

In the first group are included the diseases like anaemia, nutritional oedema, etc., in which chronic protein deficiency plays a part in the

TABLE II

Number	Total protein	Albumin	Globulin	Eu-	Pseudo-	Fibrinogen	REMARKS
				globulin			
				g. per 100 c.c.			
1	8.93	4.45	4.48	1.69	1.91	0.87	Attack of malaria 2 days later. Reported ill a month later. Clinically T.B. kidney. Had an attack of pyelitis.
2	7.26	4.07	3.19	1.07	1.72	0.42	
3	7.58	4.22	3.36	0.92	2.44	Serum	

It is proposed that individuals showing any of the manifestations such as loss of weight, loss of stamina or strength or a decreased resistance to infection should have the blood proteins examined for any possible state of protein deficiency or for the presence of mild or latent infection.

PLASMA PROTEIN VALUES IN PREGNANCY

Determinations of plasma proteins were carried out in the blood of pregnant women to ascertain the normal variations and also to find

production of hypoproteinaemia. In the second group one may include nephritis, tuberculosis, primary and secondary heart failures and also diseases of the liver such as cirrhosis, hepatitis, etc.

HYPOPROTEINÆMIA WITH NORMAL GLOBULIN

Anaemia.—Anaemia is one of the conditions to be anticipated when the protein supply of the body is reduced for one reason or another. The development of anaemia as a consequence of reduction of body protein is readily appreciated

when one considers that hæmoglobin within the cell is 95 per cent protein. 'For every gramme of iron in hæmoglobin there are some 800 grammes of protein'. If the diet is deficient in protein, it is possible that a part of the body protein has to be broken down to supply the necessary protein for the manufacture of hæmoglobin. This may result in a heavy drain on the total protein resources, during which plasma protein may be depleted.

The present report is a summary of the results of fractionation of plasma proteins on 82 cases of anæmia. Sixty-two suffered from uncomplicated anæmia. In the remaining 20 cases, anæmia was associated with certain complications, such as jaundice, ankylostomiasis, splenomegaly, etc. Fifty per cent of the cases had œdema at the time of admission to the hospital and ascites in some of the cases.

The spread of the total protein was from 7.5 to 3.75 g. per 100 c.c. The general distribution of the values was considerably below the normal range. The total protein was normal in 10 and varied from 6 to 7 g. in 26 others. A decrease in the total protein below 6 g. per 100 c.c. was observed in 46 of the 82 cases. The distribution of the values of globulin was in the lower range of normal in most of the cases.

By plotting the albumin values against total protein, a straight line was obtained as shown in figure 1, showing that a strict linear relationship exists between the total protein and

Fig 1

albumin. The equation of the straight line, determined by the customary method of least squares, was found to be as follows :—

$A = 0.886 \times \text{total protein} - 1.76$, where A is the gramme of albumin in gramme per 100 c.c. From this equation it is possible to calculate the value of albumin for a given value of total protein. Hence the value of globulin can also be accurately determined.

There is however no correlation between the total protein and albumin in those cases where certain complications were found to accompany anæmia. A glance at figure 1 is sufficient to demonstrate a sharp contrast between the two

groups. In the complicated group, the values of albumin are much below the regression line.

TABLE III
Observed and calculated values of albumin in nutritional anæmia

Total protein, g. per 100 c.c.	Albumin, g. per 100 c.c.		
	Observed value	Calculated value	Differences
7.12	4.54	4.55	+ 0.01
6.56	4.00	4.04	+ 0.05
6.00	3.54	3.55	+ 0.01
5.50	3.15	3.11	- 0.04
4.75	2.57	2.44	- 0.13
4.06	1.76	1.83	+ 0.07
3.75	1.53	1.56	+ 0.03

Nutritional œdema.—A characteristic œdema appears to be widespread during a war. The last war was no exception. Hypoproteinæmia was a constant finding in all cases of nutritional œdema.

In a study of 30 cases of nutritional œdema, the total protein was found to vary between 5 and 6 g. per 100 c.c. in 12 cases. Eighteen patients had total protein below 5 g. at the time of admission to the hospital. Albumin below 2.5 g. per 100 c.c. was present in 25 of the 30 cases. Fifteen patients had albumin below 2 g. per 100 c.c.

For the same value of total protein, the concentration of albumin in nutritional anæmia appears to be slightly higher than those observed in cases of nutritional œdema without marked anæmia. The correlation equation for the data of this group is therefore :—

$A = 0.762 \times \text{total protein} - 1.39$, where A is the g. of albumin per 100 c.c.

TABLE IV
Observed and calculated values of albumin in nutritional deficiency

Total protein, g. per 100 c.c.	Albumin, g. per 100 c.c.			œdema
	Observed value	Calculated value	Differences	
6.25	3.38	3.35	- 0.03	—
5.98	2.84	3.16	+ 0.32	—
5.48	2.86	2.78	- 0.08	—
5.12	2.62	2.51	- 0.11	+++
4.25	1.77	1.84	+ 0.07	+++++
4.16	1.70	1.77	+ 0.07	+++++
3.68	1.52	1.41	+ 0.11	+++++

Nutritional œdema is a later manifestation of hypoproteinæmia. According to Moore and Van Slyke (1930) œdema usually appears when the total protein falls below 5.5 g. and albumin below 2.5 g. per 100 c.c. The results of nitrogen balance studies indicate that a significant increase of plasma protein was difficult to demonstrate in

these patients following ingestion of high protein diet than simple maintenance of nitrogen equilibrium. A return of plasma protein to normal level followed by an increase in body weight was observed in 3 of our patients kept on high protein diet over considerable periods.

In their response to treatment with protein rich diet, the patients fall into two groups. In one there is fairly rapid and uncomplicated recovery; in the others the progress is slow and laborious. Some of the patients die suddenly and unexpectedly. This group of patients requires further study.

HYPOPROTEINÆMIA ASSOCIATED WITH INCREASED GLOBULIN

Sub-acute nephritis.—The occurrence of hypoproteinaemia in sub-acute nephritis is well known. Hypoproteinaemia in this group is usually associated with increased globulin. The range of globulin was from 3 to 4 g. per 100 c.c. Total protein below 5 g. and albumin below 2 g. per 100 c.c. was found in most of our patients. The low albumin is undoubtedly responsible for the oedema in these patients. When the patients were free from oedema, they still remained abnormal as was evidenced from the reduced albumin which persisted in some of our patients followed for more than 2 years. The loss of nitrogen in the urine does not account for such a low level of albumin so common in this condition. The albumin values can be predicted from the values of total protein by the application of the equation:—

$A = 0.384 \times \text{total protein} - 0.19$, where A is albumin in g. per 100 c.c. The calculated values agree fairly accurately with the observed values as shown in table V.

Acute nephritis.—The values of plasma protein in acute nephritis is significantly different from

TABLE V

Observed and calculated values of albumin in acute and sub-acute nephritis

Total protein	Albumin		Total protein	Albumin	
	Observed	Calculated		Observed	Calculated
g. per 100 c.c.			g. per 100 c.c.		
<i>Acute nephritis</i>			<i>Sub-acute nephritis</i>		
9.97	5.34	5.75	5.06	1.57	1.75
8.81	5.25	4.93	4.94	1.72	1.70
7.37	4.16	3.90	4.81	1.93	1.65
6.89	3.45	3.53	4.44	1.44	1.51
6.06	3.09	2.94	4.21	1.47	1.42
5.90	2.95	2.83	3.30	1.07	1.07

those observed in sub-acute nephritis. Hyperglobulinaemia present in 80 per cent of the cases was due to associated infection. The range of globulin was from 3 to 4.9 g. per 100 c.c. Total

globulin above 5 g. was present in 4 of the 44 cases. The spread of total protein was from 5.43 to 9.97 g. per 100 c.c. The concentration of albumin above 3 g. per 100 c.c. was present in 34 of the 44 cases. The oedema of acute nephritis is not referable to low albumin as is evidenced by the higher level of albumin in these patients.

The albumin values can be predicted from the value of total protein with sufficient accuracy for clinical purpose from the equation:—

$A = 0.726 \times \text{total protein} - 1.47$, where A is the albumin value in g. per 100 c.c.

Hypoproteinaemia in cardiac diseases.—Alterations in the value of plasma proteins in cardiac disease consist in a decrease in albumin associated with an increase in globulin in 75 per cent of the cases. Albumin above 3 g. per 100 c.c. was present in 90 per cent of the cases. The total globulin showed a wide range of variation—from 1.87 to 5.27 g. per 100 c.c. The extent of globulin increase determined whether total protein was normal or below normal. There is no correlation between the total protein and the albumin.

Thomson (1934) suggested that plasma protein deficiency plays an important part in the aetiology of cardiac oedema. Observations on patients with and without oedema do not justify the conclusion that deficiency of protein is a contributory factor in the causation of cardiac oedema. Oedema in cardiac cases appears at a higher level of plasma proteins as is shown by the following cases:—

TABLE VI

Plasma protein in cardiac oedema

Total protein	Albumin	Globulin	REMARKS
g. per 100 c.c.			
7.63	4.71	2.97	Breathlessness and oedema of the feet.
7.43	3.81	3.62	Cardiac failure; oedema.
7.25	3.63	3.62	Ascites and cardiac failure.
7.18	2.99	4.19	Swelling of both legs and cardiac failure.
6.37	3.37	3.50	Breathlessness; swelling of both legs.
6.50	3.00	3.50	Oedema of limbs, fluid in abdomen.

Hypoproteinaemia in cirrhosis of the liver.—Determination of plasma protein during the course of cirrhosis and other type of liver diseases have been made by several investigators. Myers and Keefer (1935) and Tumen and Bockus (1937) reported that hypoalbuminaemia was the most constant alteration of serum protein in all their patients who had chronic or advanced diseases of the liver. The elevation of serum globulin was not as significant as the reduction in serum albumin. Post and Patek (1942)

reported that a reduction of serum albumin is an essential factor in the production of ascites. Recently various authors have demonstrated a rise in serum globulin in some type of hepatic disease, especially cirrhosis.

The result of fractionation of plasma protein in 60 cases of cirrhosis of the liver showed that albumin below 3 g. and varying between 1.4 and 2.49 g. per 100 c.c. was present in 42 of the 60 cases. Our figures with regard to the low albumin in cirrhosis play only a confirmatory rôle. The increase in the concentration of globulin was as constant in this series as the lowering of albumin. The range of total globulin was much wider—from 3 to 8.31 g. per 100 c.c. The values of total protein varied according to the rise in globulin in the range of 5.65 to 19.87 g. per 100 c.c. In spite of low albumin, hypoproteinæmia was present only in 26 of the 60 cases studied.

In contrast to the foregoing data are those of 13 patients who were less severely ill. They were admitted for irregular fever and distension of abdomen and jaundice in some of the cases. Nevertheless, all of them revealed signs of cirrhosis of liver. The values for albumin and globulin varied between 3 and 4 g. in each of these patients. The total protein ranged from 6.56 to 7.62 g. per 100 c.c. The results of fractionation of plasma proteins of these patients are shown in table VI, group B.

TABLE VI

Fractionation of plasma protein in cirrhosis of liver

Total protein	Albumin	Globulin	Euglobulin	Pseudo-globulin	Fibrinogen
g. per 100 c.c.					
<i>Group A—Albumin below 3 g.; globulin varying from 3 to 8.31 g.</i>					
10.81	2.56	8.31	5.16	2.98	0.17
9.61	2.55	7.06	4.89	2.00	0.17
8.70	2.57	6.13	2.88	2.98	0.27
7.81	2.32	5.52	3.12	2.12	0.23
7.37	2.94	4.43	1.41	2.76	0.26
6.43	2.27	4.17	1.25	2.41	0.50
6.00	2.44	3.56	1.57	1.90	0.29
<i>Group B—Both albumin and globulin varied between 3 to 4 g.</i>					
6.56	3.13	3.43	1.63	1.50	0.30
6.93	3.81	3.12	0.68	2.22	0.22
7.12	3.52	3.60	1.22	2.17	0.21
7.62	3.56	4.06	1.38	2.33	0.35

The results of table VI indicate the general trend of values of plasma proteins in cirrhosis of the liver. From these results it is evident that there is no correlation between the total protein and the albumin, since globulin vary so widely. The increase in the value of globulin was almost entirely due to an increase in the

value of euglobulin, the pseudoglobulin showing a less marked but statistically significant increase. The values of total protein were related to the rise in globulin.

A study of these results does not justify any definite conclusion as to what relation the changes in the plasma protein bear to the course of the disease. From the trend of the values it would appear that the albumin tends to decrease as the disease process continues until it reaches a low level in advanced cases. We can give no reason for such a wide variation in the value of globulin. It is, however, likely that malnutrition is responsible for the low albumin in many of the patients without a marked rise in globulin. The increase in the value of euglobulin in all cases of cirrhosis is significant. Our results are in perfect agreement with the suggestion made by Stacey (1945) that euglobulin/albumin ratio may provide more sensitive indices of disordered protein formation in cirrhosis of liver. It is expected that nitrogen balance studies with high protein diet may throw more light on this point.

Conclusion

Determination of plasma proteins is of considerable clinical significance. The importance of plasma protein estimations for clinical purposes lies in the fact that unlike tissue protein they are capable of clinical measurement. Many methods have been employed for the determination of plasma proteins. Doubtless, many discrepancies in the literature are explained by the variations in the method used. The Kjeldahl procedure when carried out accurately is preferable to others in that it leads to fewer discrepancies and the results obtained are highly reproducible.

An accurate estimation of the different components of the plasma proteins is too laborious and time-consuming. From a clinician's point of view it is important to know whether the value of total protein alone is sufficient, if so, in what conditions. It is also important to know the types of cases in which an accurate knowledge of albumin and globulin is informative.

A normal value of plasma protein may be obtained even though the albumin fraction is markedly depleted. This is due to the fact that a diminution of albumin may co-exist with a corresponding increase in the globulin fraction, so that the fall in the albumin fraction is masked unless fractionation is carried out. It is for this group of patients that there is the greatest need for an accurate estimation of the values of albumin and globulin.

The usual practice of expressing the plasma protein values in terms of albumin-globulin ratio without reference to the total protein is of limited value, unless globulin remains unchanged. Interpretation of the results of plasma protein determinations from a clinical point of view is based largely upon the concentration of each

separate fraction with its independent functions and not upon the ratio of the two components.

A large number of patients are now being admitted to the hospital who have general (subcutaneous serous cavity) œdema without evidence of the usual forms of pathology which produce such waterlogging. They do not exhibit any of the clinical symptoms of renal or cardiac involvement or of liver disease. Many of these patients have excessive degree of hypoproteinaemia. The intensity of hypoproteinaemia can be ascertained from the value of total protein. The albumin values can be predicted from the value of total protein by the application of the equation $A = 0.762 \times \text{total protein} - 1.39$.

Dietary deficiency is known to cause macrocytic or nutritional anaemia. The fact that anaemia is present indicates that the preceding nutritional disturbance has existed for a fairly long time. In advanced cases, as much as 20 to 25 per cent of globulin protein may be lost resulting in hypoproteinaemia. The albumin fraction of the plasma protein seems to be the necessary replacement item. An accurate estimate of the albumin fraction may be obtained from the value of total protein by the application of the equation $A = 0.886 \times \text{total protein} - 1.76$, provided other complications do not accompany anaemia.

Protein deficiency occurs in renal conditions in which albuminuria is an important factor. Hypoproteinaemia in these patients is associated with an increase in the value of globulin due to associated infection. The values of albumin can, however, be predicted from the values of total protein by the application of the correlation equation mentioned in the text.

An accurate estimate of the values of albumin and globulin is essential in all patients with elicitable manifestations pointing to tuberculosis, cardiac disease, cirrhosis, myxoedema or a malignant growth and also in all other cases where the clinician suspects that simultaneous occurrence of two different conditions one leading to lowering of albumin and the other to an increase in globulin.

The euglobulin is considerably increased in all patients with cirrhosis of the liver. The increase in euglobulin appears to take place at the expense of the albumin fraction of the plasma proteins. In the hypoproteinaemia accompanying the cirrhosis with ascites, the determinations of euglobulin are valuable as corroborating proofs of the liver cell damage when clinical symptoms definitely point to the liver as the essential seat of the disease. In the investigation of cases of ascites due to chronic malnutrition, the estimation of euglobulin may be also valuable to the clinicians in differentiating cases of purely nutritional deficiency from those where latent liver disease is suspected.

In clinical practice, a single determination of plasma proteins may not prove to be of much value. Repeated determinations often provide valuable information concerning the state of the patient because they reveal the course of

the disease through deterioration or improvement.

CHOLINE DIHYDROGEN CITRATE IN INFANTILE BILIARY CIRRHOSIS

By S. BALASUNDARAM

Director, The Ehrlich Laboratory, Balaji Nagar, Royapettah, Madras

INFANTILE biliary cirrhosis has been accepted as a separate clinical entity for nearly a decade now. The toll of infants taken by this disease in various parts of India should justify a record and classification of deaths due to this disease under a separate head. But the public health authorities throughout India have not been impressed to the extent desirable to make them understand the necessity for such a record.

The result of this position is that an investigator who wants to investigate the aetiology of this disease lacks the preliminary statistics of its incidence and death rate. Each investigator is left to his own resources and capacity to get the necessary data and do the investigations. Work by me in this direction was published in five articles in the *Indian Medical Journal* (*I.M.J.*, Vol. 33, No. 11, November 1939; *I.M.J.*, Vol. 34, No. 2, February 1940; *I.M.J.*, Vol. 34, No. 3, March 1940; *I.M.J.*, Vol. 34, No. 5, May 1940; *I.M.J.*, Vol. 35, No. 12, December 1941). The sum and substance of those articles is that :—

1. The disease is fairly widespread.
2. The incidence is greater in some parts of Madras Presidency, the Central Provinces, the southern portion of Bengal and Bombay Presidency.
3. The male sex shows a greater proclivity to the disease.
4. The children suffering from it are those fed on rich and fatty diet.
5. The habitual administration of castor oil is likely to be responsible in some cases on account of its being a thick fatty oil capable of damaging the liver cells.
6. The children suffering from this disease are predisposed particularly on account of hyperactivity of some of the endocrine glands.

Though these points give us an idea of the predisposing causes of the disease the exciting cause has not been found to be definite. Bacteriological investigations made repeatedly by various observers have brought forth nothing except that in some cases *B. coli* have been found to grow in the cultures of urine of patients suffering from the disease. But the theory of the organisms being responsible for the causation of cirrhosis, etc., is not acceptable to many. In the absence of specific extraneous causes endogenous toxins and non-specific proteins have been thought of. But these again do not account for all the cases. The conclusion, therefore, is that in children predisposed to this disease cirrhosis is easily brought about by any one or a combination of a number of cases.

The pathological findings in the structure of the liver in this disease have been as follows :

1. Varying degrees of necrosis of the liver cells uniformly distributed throughout the organ.
2. An avascular non-inflammatory oedematous connective tissue network enclosing in its meshes small islands of hepatic parenchyma of unequal sizes and in varying degrees of degeneration.
3. An obliterative lesion of the terminal and some of the bigger divisions of the hepatic venous tree without appreciable changes in the portal venous and biliary trees.
4. Areas showing disorganization of the reticulum of the sinusoidal capillary bed mostly around the hepatic venous terminals.

5. An unsuccessful attempt at regeneration of the hepatic parenchyma as evidenced by the small size of the rounded lobules of the liver cells distributed throughout the organ.

The treatment has naturally to remove the cause. Most of the preventable causes can be tackled but the cirrhosis itself has been found to be difficult to counteract.

For diminishing the tendency of the liver to produce the enormous amount of fibrous tissue at the expense of the liver cells, in the absence of any suitable drug, various methods of empirical treatment in the form of administration of vitamins, calcium, iron and such other things have been tried with little or no effect. A few cases which are on the border line of health and disease get well but in typical cases of cirrhosis this sort of empirical treatment is of no avail.

This fact of a lack of a suitable drug to treat the disease made me turn to other countries to find out how they were dealing with cases of this type. A searching enquiry both into the literature and the incidence of this disease in countries like America has shown that though cirrhosis of the adult variety is fairly common, the clinical entity as observed by us in cases of infantile biliary cirrhosis in India is not found there. Nevertheless I thought it would be to our advantage if we can know whether the clinicians there were able to treat successfully at least cases of cirrhosis of the adult type. With this aspect in view, I contacted Eli Lilly and Company who were kind enough to send me samples of choline dihydrogen citrate tablets which were found to be useful in cases of cirrhosis of adults.

I have been administering this drug to all children suspected to be suffering from this disease. Altogether 102 cases were tried. 75 of these were children under 2 years, 16 of them between 2 and 3 years and 11 under 1 year. 62 of them were early cases with only slight enlargement of the liver, and palpable spleen, slight anaemia, phosphates in urine, irritable temper and a slight diminution of weight. All these cases recovered within two weeks of the administration of the drug. Three to four tablets a day were given. Injections of liver extract with vitamin B were given in older children. Liver began to diminish in size. Children began to put on weight. Activity became normal and irritability gave place to cheerfulness. Rice diet has been found to be agreeable to most of the children except a few young ones who were on milk diet. Excess of fat was avoided in all these cases.

13 cases came after ascites had set in; 4 of these only recovered, in whom there was just a small quantity of fluid. The other cases in which ascites was marked ended fatally.

17 cases came with other intercurrent ailments, complicating the cirrhosis. All these cases recovered. In most of the cases ascariasis

infection was present. Malaria, kala-azar, etc., were also noted in some cases.

Three cases came in an advanced state of the disease and all of them ended fatally in spite of treatment.

Thus it will be seen that in a total of 102 cases carefully selected for treatment with choline dihydrogen citrate 79 recovered, though some of them are still taking the drug. It may also be noticed that the drug is of great value in early cases where the damage to the liver cells has not been much and where recovery is easy and possible without much difficulty.

The ease with which the drug can be administered and the absence of ill-effects are the special advantages of the drug. The only trouble met with is occasional diarrhoea. The drug is then stopped. It can be again administered as soon as the intestinal irritability subsides.

OBSERVATIONS ON AN OUTBREAK OF KALA-AZAR IN CALCUTTA

By P. C. SEN GUPTA, M.B. (Cal.)

Officer-in-charge, Kala-azar Research Department,
School of Tropical Medicine, Calcutta

ABOUT a quarter of a century ago, Knowles, Napier and Das Gupta (1923) showed that kala-azar was prevalent in an endemic form in certain areas of Calcutta, inhabited mainly by poorer classes of Anglo-Indians, Indian Christians and Mohammedans. In spite of the fact that large numbers of imported cases resided in other areas of the town very few or no cases of kala-azar occurred amongst the permanent residents of these apparently non-endemic areas. They concluded that the conditions requisite for the transmission of kala-azar from one patient to another were at their best (or worst) as far as Calcutta was concerned in that endemic area of the city. It is interesting to recall that the investigations and experiments carried out mainly by the workers of the School of Tropical Medicine, Calcutta, the Kala-azar Commission of India and other kala-azar research units of the Indian Research Fund Association that followed this observation during the next two decades led first to the incrimination of the sand-fly, *Phlebotomus argentipes*, as the vector of kala-azar, and finally the solution of the kala-azar transmission problem, when Swaminath, Shortt and Anderson (1942) succeeded in transmitting the disease to human volunteers by the bite of the sand-fly.

The data that formed the basis of this pioneer epidemiological investigation were collected by Napier at the kala-azar clinic of the Calcutta School of Tropical Medicine. This clinic was opened at the beginning of 1921 and during the first year the attendance increased month by month and a steady level was reached in a year or two. This was the first out-patients' clinic for

kala-azar in Calcutta at the time of its inception. Though other out-patients' clinics were started in the city during the next few years, the attendance of the patients at this clinic has been quite considerable on account of its popularity and suspected cases of kala-azar from different parts of the city as well as those imported from different parts of Bengal and the neighbouring provinces attend for diagnosis and treatment. The clinical and epidemiological data relating to the indigenous kala-azar cases may thus properly be regarded as pertaining to a representative statistical sample of the kala-azar cases in the city.

During the years following the Bengal famine of 1943, it was found that steadily increasing numbers of cases of kala-azar and those with grave complications were being encountered at the kala-azar clinic of the School of Tropical Medicine, Calcutta. A study of the epidemiological and clinical data collected during the routine investigation of the patients attending the clinic or admitted into the Carmichael Hospital for Tropical Diseases was undertaken. In this paper it is proposed to present the results of this study under three principal headings, (a) the trends of incidence of kala-azar in Calcutta, (b) the distribution of the disease in Calcutta, and (c) the variation in the clinical picture of kala-azar seen during the period following the famine and then to discuss these findings and consider the epidemiological factors concerned with the outbreak of kala-azar in Calcutta.

The trends of incidence of kala-azar in Calcutta

As indicated previously the figures relating to the indigenous kala-azar cases attending the clinic at the School of Tropical Medicine, that form a representative sample of the kala-azar affected population of Calcutta, have been utilized for the study of the trends of incidence of the disease in the city. It has been found out that about half of the total number of kala-azar cases attending the clinic are indigenous cases (see table I and chart 1). From these two, i.e. the chart 1 and the table I, the trends of incidence are readily ascertained.

It will be seen that there was a peak of incidence in the year 1923 and the number of cases remained practically steady for the next two years, and then gradually the number of cases decreased till a more or less steady inter-epidemic level was reached and maintained from 1930 to 1943. The low figure in 1942 was due to partial evacuation of the population on account of the war scare. The next wave of increased incidence commenced with a rise in the number of cases in 1944; by 1945 the rise was well marked and in 1946 a high peak was reached. This rise of the number of cases of kala-azar is even more strikingly shown by the chart showing the number of new cases of kala-azar per month since 1943 (see chart 2). The rise was gradual but steady from 1944 till

TABLE I

GRAPH I.

February 1946, and since then there was a steep rise that reached the peak in July to August 1946. From the 16th August, 1946, the number of cases dropped suddenly on account of the grave disturbances that commenced in the city on that date and most of the patients were unable to attend for treatment. Since that date the attendance was very variable on account of the persistence of the disturbances and figures relating to the attendance of the patients after this date are thus not of any value statistically.

The distribution of kala-azar in Calcutta

Three spot maps of Calcutta (maps 1, 2 and 3) are given below. These show the distribution of the indigenous cases of kala-azar in the city. The map 1 is from Knowles *et al.* (1923) and is included in order to show the distribution in 1922-23. In this and the other maps only those cases of kala-azar have been included as 'indigenous' that were in patients who had lived all along in Calcutta since their birth and those who had been staying in the city for at least 2 years before the onset of the symptoms of kala-azar.

On examination of these maps 1 and 2 it will be found that during 1942-43 the distribution of kala-azar in Calcutta was very similar to that described in 1922-23 by Knowles

Map 1.

Indigenous kala-azar cases.

and his colleagues. The wards described by them as the endemic area of kala-azar were as badly affected as previously. Comparison of the maps 2 and 3 shows that in 1945 and 1946, apart from the fact that there was a large number of cases from the kala-azar endemic area, increasing numbers of cases were seen from other areas of Calcutta particularly from those in the north-eastern and south-western fringe of the town.

The other fact elicited was that in a large proportion of cases the patients came from the bustees of Calcutta. From certain bustees a fair number of cases were encountered every year. Inside the city these bustees can truly be regarded as the home of kala-azar. The other type of kala-azar houses were the old-time buildings, not in good repair, and the servants' quarters and the out-houses and the dwellings of the well-to-do people.

Also an analysis of the records of the indigenous cases showed that in 1946, 209 were in Moslems, 160 in Hindus, 19 Indian Christians,

Map 2.

Kala-azar in Calcutta (indigenous cases).

Map 3.

and 27 Anglo-Indians and one Chinese; of the imported cases the corresponding figures were 139, 250, 6, 4 and 2.

Variations in the clinical features of kala-azar, during the outbreak

It is well known that in India the highest incidence of kala-azar is among the children between the ages of 5 and 15 years. During the period following the famine it was found that quite a large number of adult patients were suffering from kala-azar. The following table gives the age incidence of kala-azar cases seen at the kala-azar clinic during 1946 and that given by Napier (1943) as typical for Asian endemic areas generally. Napier's figures were collected from a rural area near Calcutta.

The table shows that the age groups 5 to 10, 10 to 15, 15 to 20 and 20 to 30 were more or less equally affected by kala-azar in 1946, and even in the age group 30 to 40 the proportion of cases was higher in 1946 than the figures in Napier's table of age incidence. It may be concluded that in 1946, the children and adults were more or less equally affected and even older people were not spared.

The history about the onset and the progress of illness is unreliable in many of the patients attending the kala-azar out-patients' clinic; so it is not proposed to discuss the presence of variations in the course of kala-azar on the data collected at the out-patients' clinic. But the general impression gained was that the patients appeared to be more seriously ill than in the previous years, and the serious complications were more frequent. An analysis of the case notes of the kala-azar patients admitted into the Carmichael Hospital for Tropical Diseases during 1935 to 1939 and 1943 to 1946 is presented below in order to show the occurrence of the serious complications of kala-azar during these periods, the former being an inter-epidemic period and the latter that of an outbreak of kala-azar (see table III).

This table shows that the grave complications were much more frequent both as regards the types of complications and their relative incidence during the period 1943 to 1946 and more so during 1945 and 1946 than during 1935 to 1939. For example, during 1935 to 1939, 233 cases were admitted into the hospital; of these only 4 had cancerum oris (1.7 per cent); and during 1943 to 1946, 420 cases were admitted, of which 30 (7.1 per cent) had this complication. Respiratory and gastro-intestinal complications, generalized oedema, hæmorrhages, jaundice, severe anæmia, pneumococcal meningitis, etc., were not infrequently seen. Agranulocytosis as a grave complication of kala-azar, the first case being reported from India only in 1942, was encountered in no less than 3 cases in 1946 and two more cases were seen during the first six months of 1947.

Discussion

The marked increase of kala-azar, as shown by the graphs and tables above, indicate that there was an outbreak of kala-azar affecting a large number of people, i.e. there was an epidemic of

TABLE II

kala-azar in Calcutta; the peak of the epidemic was apparently reached about the middle of 1946. (The data collected after the 16th August, 1946, was not representative on account of the persistent disturbances in the city). The increase of kala-azar was up to about four times the level during the inter-epidemic period 1930 to 1943.

It is now proposed to consider the general factors affecting the population of Calcutta that formed the background of and probably led to this outbreak of kala-azar.

According to Napier (1943), a concatenation of climatic or other factors, such as widespread distress after an earthquake or an influenza epidemic, determines a general increase and that local conditions and population factor determine the extent and duration of the outbreak; when all the susceptible material, *i.e.* the children born

since the last epidemic wave, is exhausted, the disease dies down.

The epidemiological factors that are now being considered are discussed under the following headings: (a) climatic factors; (b) the effect on the population of general economic distress, famine and war-time conditions; (c) outbreaks of other diseases, particularly malaria just preceding the outbreak of kala-azar; (d) the population factor, *i.e.* the presence of highly susceptible material in the population particularly in the form of children born since the last epidemic wave; and (e) the question of increase of virulence of the parasite, *Leishmania donovani*.

In order to find out if there was any difference in the climatic conditions during an epidemic period, the average maximum and minimum temperature, humidity and rainfall during the periods 1921 to 1925, and 1943 to 1946 and the

inter-epidemic period 1935 to 1939 were studied in detail. No marked difference was apparent or any particular type of departure from the conditions during an inter-epidemic period seen during the epidemic periods. The chart shows the average maximum and minimum temperatures, humidity and total rainfall per month during the three periods and it will illustrate the above findings.

The other fact that appears interesting is that during the months of July, August and September and possibly parts of June and October as well, the climatic conditions are at an optimum level in Calcutta for the development of the leishmania in the sand-fly. It is known that the leishmania grow best in the sand-fly at about 28°C., i.e. about 82.4°F., in the presence of high humidity of over 80 per cent (Smith, *et al.*, 1940; Swaminath *et al.*, 1942). The mean temperature during these months is about 84°F. and the fluctuation above and below the mean about 5°F., and the humidity is above 85 per cent.* It may be mentioned that during these months sand-flies are found in relatively large numbers in the endemic areas of Calcutta (Napier and Smith, 1926).

The effect on the population of general economic distress, famine and war-time conditions

The year 1943 saw serious economic distress and food scarcity followed by a grave famine that affected the whole of Bengal and led to the death of 1.5 to 3.5 million people according to different estimates. The worst period of the famine was during the months of August, September, October and November 1943 and even for months afterwards considerable economic distress persisted. During this period except for the distress caused by the relative scarcity of food, the indigenous population of Calcutta did not undergo the ordeal of the famine to the same extent as the rural population of Bengal. But the population of Calcutta was brought into close contact with the famine-stricken 'destitutes' from the districts of Bengal who came into Calcutta during the famine. Apart from the insanitary conditions that were inevitably associated with this influx of destitutes who died by thousands on the streets and in improvised shelters and relief hospitals of Calcutta from the effects of starvation and the various diseases (for fuller details, see Fitch, 1947), the other factors that came into operation on the population of Calcutta were (a) the introduction of newer strains of disease-producing organisms and (b) overcrowding, particularly in the poorer class localities and the outskirts of the town where destitute camps were located. It is generally believed that the epidemic of malaria of 1943-44 was to a great extent due to the introduction of

new and virulent strains of the parasite by the famine-affected rural population.

During 1942 and the years following Calcutta was a military base, and apart from the influx of the armed forces from the different parts of the world, there was frequent movement of the military personnel and labourers, considerable proportion of which was from non-kala-azar areas and thus quite non-immune to this disease, between Calcutta and the forward areas in Assam and East Bengal which are bad kala-azar areas. Also large numbers of factories were started in and around the city for the supply of war materials and this led to an influx of the rural population into the city in search of employment. The immediate effect of this was overcrowding of the *bustees* to a marked extent (and of the better class residential quarters to a less extent) and the introduction of disease-carrying population into these areas. (From chart 1 and table I it will be seen that there was an increase of both *imported* and indigenous cases of kala-azar during this outbreak.) Sanitation, never satisfactory in the *bustees* and quarters of the poorer classes, was rendered much worse on account of the overcrowding and the conservancy rendered insufficient by war-time conditions and other disturbing factors.

The effects of these factors, *viz* general economic distress, famine and war-time conditions, were chiefly the lowering of resistance to diseases due to under-nourishment, overcrowding in the *bustees* and the dwellings of the poorer classes of the population mainly and the presence of imported and indigenous disease-carrying population in these areas, thus increasing the chances of kala-azar affected and non-infected people living in close proximity and amidst insanitary surroundings rendered worse by war-time conditions and overcrowding. This last-named factor, *viz* insanitary surroundings, really meant accumulation of garbage, excreta of animals in and around the *bustees* and the dwellings of the poor that had fallen into disrepair, thus providing excellent breeding grounds and shelters for the sand-fly, *Phlebotomus argentipes*, the vector of kala-azar in India.

Outbreaks of other diseases, particularly malaria, previous to the epidemic of kala-azar

The famine of 1943 brought in its wake the outbreaks of several diseases in Calcutta. The principal diseases were cholera (1943), small-pox (1944), enteric fevers and malaria (1943-44). That attacks of these diseases can lower the body resistance of the population already devitalized by food scarcity is quite probable, but the importance if any of the above diseases in leading to the outbreak of kala-azar has to be examined in some detail.

Cholera.—The outbreak of cholera began in October 1943 and the worst affected areas were the wards 27, 22, 28, 29 and 9 in 1943 and the

*The mean temperature is probably lower and the daily variations much less, probably not more than 1°F. in the natural shelters of the sand-fly during this period (Napier, 1927).

wards 18, 23, 26 and 32 in 1944. Except for the wards 28, 29 and 18 which were affected by other diseases as well, there was little or no kala-azar in the remaining wards affected by cholera. There was no serious outbreak of cholera in the kala-azar endemic area of Calcutta.

Small-pox.—This disease has little relation with the outbreaks of kala-azar. In Calcutta usually there are epidemics of small-pox every fourth or fifth year and there are frequently two outbreaks, a milder outbreak during a pre-epidemic year followed by a severe epidemic year. These outbreaks have no time relation with kala-azar. The wards 29 and 27 were the worst affected areas in 1943 and from the former ward many cases of kala-azar were seen in 1945-46; this area was however affected by other diseases as well in 1943-44.

Enteric fevers.—The enteric group of fevers is regarded as one of the factors capable of dissemination of leishmanial infection from a quiescent focus of infection in the skin to the visceral reticulo-endothelial tissue, thereby establishing a general visceral infection, i.e. kala-azar. The enteric fevers are endemic in Calcutta and occur all the year round. In 1943 the worst affected areas were the wards 1, 9, 22 and 27 and the wards 3, 22 and 23 in 1944. These wards are not included in the kala-azar endemic area of Calcutta, and very few kala-azar cases were seen in these wards in 1944 to 1946. Though this finding does not in any way disprove the hypothesis about the importance of the enteric fevers in the production of kala-azar, the fact may be mentioned that there was no serious outbreak of enteric fevers in the kala-azar endemic area of Calcutta during the period preceding or coincident with the outbreak of kala-azar in 1944 to 1946.

Malaria.—Like the enteric group of fevers malaria is regarded as an important factor in the causation of a visceral dissemination of leishmanial infection from a quiescent focus in the skin of an individual bitten by an infected sand-fly. Epidemiological and cytological evidence was produced by Napier and his associates in support of this hypothesis.

In Calcutta there was a serious outbreak of malaria that began in September 1943; the peak was reached in October-November of the same year and though the number of cases came down considerably in December and still further in the following months the figures remained at a high level until September 1944, when another serious epidemic of malaria started. The peak of this outbreak was reached in November 1944, and then a sharp decline commenced in December 1944, and the normal level was reached in March 1945 (see chart 2). It will be seen that the increase in the number of kala-azar cases began in 1944, a high level was reached in 1945 and the rise continued to an even higher level in 1946. Though there was an outbreak of malaria preceding the rise of kala-azar in 1944 and 1945, there was no such increase of malaria

in 1945 preceding the further increase of kala-azar in 1946.

During 1943 the worst malaria affected areas in Calcutta were the District III, comprising of

the wards 13 to 21, and the 'added areas' particularly the wards 28 and 29. During 1944, the worst affected areas were the wards 18, 28 and 29. The wards 28 and 29 constitute the

north-eastern fringe of the town. There was also a somewhat milder outbreak of malaria in the ward 24 in the south-western part of the city. From these areas in the north-eastern and south-western fringes of the city that were badly affected by malaria in 1943-44, increasing numbers of cases of kala-azar were seen in 1945-46. The wards 13 to 21 include the kala-azar endemic area of Calcutta from which also

a large number of indigenous cases of kala-azar was seen in 1944 to 1946.

It would thus appear that malaria was probably of importance in the causation of the outbreak of kala-azar in 1944 to 1946. But there appears to be a distinct time lag between the

outbreak of malaria and the onset of the epidemic of kala-azar. Such time lag was experienced by Smith and Ahmed (1941) who investigated the relationship between an outbreak of malaria and that of kala-azar in Bihar (see chart 4). The writer also had similar experience during his investigations of outbreaks of kala-azar in the Chittagong District in 1945 (see chart 5) and at Baniachang in the Sylhet District in 1947. In the latter village the indications were that an outbreak of kala-azar

commenced in 1944 after the grave epidemic of malaria of 1943 that is reported to have caused the death of 25 per cent of the total population of the village; and between January 1945 to February 1947, at least 4.5 per cent of the surviving population of the village showed evidence of well-developed kala-azar.

This time lag is presumably due to two factors: (1) the interval between the carrying of the parasitized histiocytes from the skin to the viscera, as a result of repeated attacks of malarial fever that leads to a well-marked mobilization of the histiocytes, and the onset of the symptoms of kala-azar; and (2) the duration of illness from kala-azar after which the patient comes under observation and is diagnosed as a case of kala-azar on the basis of the aldehyde test in most cases. The incubation period of kala-azar is generally regarded as two to four months though it is well recognized that the extreme limits may be anything from a few weeks to a year and a half; and most patients come for treatment after more than three months' illness, and the maximum after six months of illness from kala-azar (Napier, 1926). This explains the time lag of about 5 (if diagnosed by blood culture or other tests) to 8 months (if diagnosed on the basis of a positive aldehyde test) between the peak of an outbreak of malaria and that of kala-azar at its onset. Once the epidemic has started it progresses to the peak even in the absence of any other disease like malaria (see charts 2, 4 and 5).

The population factor, i.e. the presence of highly susceptible material in the population particularly in the form of children born since the last epidemic wave.

Napier showed that in India the incidence of kala-azar was the highest amongst the children below the age of 15 years and thus they constituted the highly susceptible material for infection. The peak of the last epidemic was in 1923 and Napier calculated that in 1943 the next epidemic wave was overdue by about five years and ascribed this to the treatment campaign against kala-azar (Napier, 1943). But if we examine chart 1, it is seen that the epidemic wave of the twenties terminated about 1929 and the interepidemic period commenced in 1930. If we calculate from the year 1930 the aggregation of the susceptible children below the age of 15, born from 1930 to 1946, is at the maximum from 1944 onwards. Thus in 1944 the soil for an outbreak was ready among the children born since the passing of the last epidemic wave.

In 1944 the susceptible material in the population was probably not made up of children alone. Food scarcity, famine, war-time conditions, and outbreaks of several diseases had in all probability rendered even the adult population relatively more susceptible to kala-azar. That older age groups were more frequently affected by kala-azar in 1946 was probably due to this factor and/or increased virulence of the parasite.

It thus appears that the presence of highly susceptible material in the population is an important predisposing factor in the causation of an outbreak of kala-azar.

Napier had pointed out that the population factor determines the extent and the duration of an outbreak of kala-azar; when all the susceptible material is exhausted the disease dies down. This is quite true for localized communities without much facilities for treatment. But under modern conditions the duration of an epidemic should depend entirely on the intensiveness of the treatment campaign and anti-sand-fly measures.

The question of increase of virulence of the parasite, Leishmania donovani

Though the possibility of increase of virulence of leishmania was suspected by other workers (Shortt *et al.*, 1931), it has not been established that the virulence of leishmania may be increased in an endemic area; but the findings made during this epidemic are in favour of this change having taken place. Actually there does not seem to be any reason why the virulence of leishmania, an infective organism, should not increase after several passages through very susceptible individuals. The evidences are that as a result of the factors the effects of which have been described above, the population of Calcutta was rendered very susceptible in 1943-44 and as a result of passage through this highly susceptible population, the virulence of the leishmania increased and the increase of incidence of 1944 progressed to an epidemic during the next two years. The progressive increase of incidence and of the severity of the disease was noticed from 1944 to 1946, and this fact supports the hypothesis of the increase of virulence of the parasite after passage through highly susceptible population, most of the other epidemiological factors, such as the war-time conditions, famine, epidemics of other diseases, etc., having ceased to operate in 1945-46.

Summary

A study of the trends of incidence, epidemiological and clinical data relating to a representative sample of the indigenous kala-azar affected population of Calcutta, showed that there was an outbreak of kala-azar in the city during the years following the Bengal famine of 1943. The disease was increasingly prevalent not in the endemic area of Calcutta alone, but also in the outskirts of the town that were affected by a serious outbreak of malaria in 1943-44. The peak of this epidemic was apparently reached about the middle of 1946. During this outbreak, the disease was more virulent in type than is usual during the inter-epidemic periods in Bengal; serious complications were more frequent and the older age groups were almost equally affected as the children.

Of the epidemiological factors that were concerned with this outbreak of kala-azar, the

aggregation of highly susceptible material in the population in the form of children below the age of 15 years born since the last epidemic and to some extent of the adult population affected by war-time conditions, famine, and epidemics of various other diseases, was of great importance. The effect of these factors, e.g. war-time conditions, food scarcity, and famine, was mainly to lower the body resistance of the population, increase the chances of close proximity between the infected and the unaffected individuals as a result of overcrowding, and providing excellent breeding grounds and shelter for the vector sand-fly, by the aggravation of the insanitary conditions in and around the dwellings of the poorer classes. The outbreaks of several diseases, viz cholera, small-pox, enteric and malaria, further lowered the body resistance of the people, and the last-named disease probably helped to light up the quiescent leishmanial infection in many individuals at the onset of the epidemic. The indications are that by the passage through this devitalized and highly susceptible population, the virulence of the parasite was enhanced and the epidemic was maintained and progressed to the peak even when most of the other epidemiological factors had ceased to operate.

The writer is thankful to Dr. M. N. Rao, M.B., B.S., M.P.H., D.P.H., of the All-India Institute of Hygiene and Public Health, and the Superintendent of the meteorological department at Alipore, Calcutta, for the data relating to the climatic conditions in Calcutta used in this paper, to Dr. S. C. Seal, M.B., of the All-India Institute of Hygiene and Public Health and the Health Officer, Calcutta Corporation, for the information regarding the outbreaks of diseases in the city and to the officers of the Public Health Department of Chittagong and Assam for the morbidity figures of Chittagong District and Baniachang respectively.

SEROLOGICAL TECHNIQUE (contd.)

By S. D. S. GREVAL

LIEUTENANT-COLONEL, late I.M.S.

(From the Laboratory of the Imperial Serologist and Chemical Examiner to the Government of India, School of Tropical Medicine, Calcutta)

DETAILS OF COMPLEMENT FIXATION IN HYDATID DISEASE

The Technique

The hæmolytic system.—This is taken from the LCF reaction, as in the case of complement fixation for kala-azar and leprosy observing the same rule of preference for the complement.

The antigen.—From carcasses of freshly slaughtered infested sheep fluids from a dozen or so hydatid cysts are collected by aspiration with a syringe in separate bottles. The needle is left *in situ* while the syringe is filled and discharged into a bottle. Finally the needle is made to scrape the cyst wall and the contents aspirated for preparing a slide for microscopic examination. The scoleces must be demonstrated before a fluid is accepted for the test.

To each bottle is added on the spot 0.5 per cent (or a little over, up to 0.6 per cent) of a mixture of equal parts of ether and trikresol. (For small quantities drops from a standard capillary pipette delivering 50 drops to 1 c.c. are used. Each drop equals 0.02 c.c. Such a pipette is made by fitting the point in hole no. 58 of wire gauge of L. S. Starrett Co., U.S.A. The required percentage of trikresol can be added by this pipette to quantities as small as 0.5 c.c., by diluting the antiseptic with more ether). The bottles are shaken vigorously, brought to the laboratory and left in a refrigerator overnight. Next day each fluid is tested for anticomplementary and hæmolytic activity. One volume of it should not interfere with 1 MHD of complement (antigen 1 vol. + saline 1 vol. + complement 1 MHD in 1 vol. . . . incubation . . . + sensitized rbc 1 vol. . . . incubation = almost complete hæmolysis) and 3 volumes should not hæmolyse 1 vol. of sensitized rbc suspension (antigen 3 vol. + sensitized rbc 1 vol. incubation = no hæmolysis). The fluids not conforming to the standard or discolouring the rbc are rejected.

At least 6 selected fluids are pooled to yield a standard antigen which remains stable in a refrigerator at least for a year. For use the bottle is shaken, the coarse particles allowed to settle and the uniformly opalescent fluid removed.

The serum. 1. *Under test.*—It is inactivated and diluted 1 in 10, 1 in 50, 1 in 100 and 1 in 200.

2. *Known positive.*—A positive serum of a known titre diluted 1 in 10 with saline containing 0.25 per cent trikresol is kept in the refrigerator. It keeps well and need not be re-inactivated unless it has turned anti-complementary. As the sera for the test are not received frequently such a serum may at times be not available. Reliance then must be placed on 6 negative controls, 3 LCF positive and 3 negative. Serum from a case of gonorrhœa, if available, is also included.

3. *Known negative.*—For reasons given above many controls may be necessary. The sera need not be re-inactivated if they have been used in other tests the same day. One LCF positive control, from a case known to be free from hydatid diseases, is always included.

Charging of tubes.—Five tubes are required for each case and charged thus:—

A column

All tubes contain complement with 2 MHD contained in 1 volume.

5th row tube with :	Serum 1 in 200, 1 volume. Antigen, 1 volume.
4th row tube with :	Serum 1 in 100, 1 volume. Antigen, 1 volume.
3rd row tube with :	Serum 1 in 50, 1 volume. Antigen, 1 volume.
2nd row tube with :	Serum 1 in 10, 1 volume. Antigen, 1 volume.
1st row tube with :	Serum 1 in 10, 1 volume. Saline (no antigen), 1 volume.

(Antigen and complement are mixed and delivered as a double volume after the serum has been delivered, except, of course, in the 1st row tube which contains no antigen.)

Left at room temperature and incubated as in LCF.

Sensitized rbc, 1 volume, added to all tubes. Incubated $\frac{1}{2}$ hour.

An antigen control is included for the day's work. It consists of (i) antigen 1 vol. + (ii) comp. 1 MHD + (iii) saline 1 vol. It is left at room temperature and in the incubator like the rest of the tube and tested for loss of complement by adding rbc suspension 1 vol. There should be no loss. The rbc should be almost completely hæmolyzed.

Reading of results.—The results are read (i) immediately for \pm and $-$ and (ii) next day for $+$ and T after the tube has stood in the ice-box overnight. A $?$ — is ignored.

Record and report. 1. *When the serum control (1st row tube) is fully hæmolyzed.*—A $+$ is reported as 'Positive in 1 in 200', 'Positive in 1 in 100', 'Positive in 1 in 50' or 'Positive in 1 in 10'. A T or \pm in the 2nd and 3rd tube is recorded as such under each tube but reported as 'Doubtful'.

2. *When the serum control is partially hæmolyzed \pm .*—A $+$ in the 3rd row, 4th row

or 5th row tube is reported as 'Positive in 1 in 50', 'Positive in 1 in 100' or 'Positive in 1 in 200'. For a + in the 2nd row tube only the serum must be diluted and tested until the 1st tube is fully hæmolyzed.

3. When the serum control is not hæmolyzed at all or shows only a trace of hæmolysis (T).—The serum must be diluted and tested until the serum control is fully or partially hæmolyzed.

Observations on the Technique

Limitations of the technique.—Unlike what obtains in syphilis, kala-azar and leprosy, the limit of reaction of the sera from cases of hydatid disease is not known. The antigen has not been standardized by selection with respect to its sensitiveness. That is why degrees have not been assigned to the reaction. By stating the strength of the serum dilution which gives a + reaction, however, a comparison is possible.

Special features of the technique.—There are four such features: (1) The antigen is selected with respect to its hæmolytic and anticomplementary activity, pooled, and preserved. The pooling makes the antigen polyvalent and the preserving relatively constant. (2) The serum is tested routinely in four well-spaced dilutions. (3) The dose of the complement is constant. (4) The complement of a poor quality, as determined in its titration in the LCF for syphilis, is not used. This restriction on the complement ensures obtaining of repeatable results in weak reactions.

REPETITION OF THE REACTION

For technical reasons.—From what has been said concerning the preference for the qualities of the complement, it follows that a doubtful reaction not in accordance with clinical expectation or not giving enough aid in diagnosis should be repeated with a complement of a better quality (if an inferior quality has been used before) in order to obtain more fixation. This is necessary in view of the fact that adjustment like those in the LCF are not made in this reaction.

The repetition is also indicated when the MHD of the complement selected for the LCF has given a fixation rather on the low side in that reaction.

Enough serum should be available for the repetition from the original sample. If a fresh sample be necessary the preparatory measure of taking the blood early in the morning, before any food has been taken, if ignored previously, should be enforced now.

For observing the course of the disease.—Fresh serum will, of course, be necessary for observing, increasing or decreasing fixation, with treatment other than surgical. The author believes that the hydatid disease undergoes spontaneous cure in India.

INCIDENCE OF COCCIDIOSIS IN THE ARAKAN

By N. N. MUKHERJEE
late CAPTAIN, I.A.M.C.

SINCE the discovery of *Isospora hominis* by Kjellberg, Virchow (1860), Railliet and Lucet (1890), Woodcock (1915) and Wenyon (1915), various workers reported about 200 cases from various parts of Europe, Asia, Africa and America. The highest figure of incidence recorded in one zone is 32, which was from Eastern Mediterranean. The following records of cases are available from East Asia according to Wenyon:—

Noc (1920) reported a doubtful case from Saigon.

Brug (1922) reported four cases from Java.

Pons (1925) reported another two cases from Saigon.

Boon van Ostade (1923) reported a case from Malay.

Wassell (1923) reported a case from China.

Knowles (1924) reported five cases from Calcutta.

Das Gupta (1934) encountered one case in Calcutta.

Galliard (1936) found a case of pure infection in Saigon.

Pons, Dufosse and Legar reported a number of cases in Europeans only from Indo-China.

Writer's own observations.—The writer in the Arakan on the Eastern Frontier of South Bengal encountered 14 cases during a period of about 7 months and the findings are condensed in the table appended. During this period, examinations of more than 6,000 specimens of stool were undertaken from over 1,000 cases, both British and Indian soldiers fighting in this area. Twelve cases out of 14 were diagnosed by direct examination of stool slides and the remaining 2 (cases 9 and 11) by Sheather's concentration method (sugar flotation). Duodenal fluids were examined in 2 cases (cases 8 and 12) with negative results. A series of more than 50 cases of diarrhoea showing Charcot-Leyden crystals and fat were examined by Sheather's concentration method without any promising result. Charcot-Leyden crystals, fairly constant in this infection, were absent in 2 cases (cases 5 and 13). Fatty acid crystals and fat globules were present only in 3 cases (1, 3 and 8). Most of the cases except cases 2, 5 and 6 had loose, light coloured stools with undigested food material. All the cases were confined to British troops. Practically all the cases were from units in the same area, and occurred between the months of May and October and the peak of incidence corresponded to the peak of the monsoon.

Summary of findings in 14 cases of Coccidiosis

Case number	Date	Exudate	Associated pathogenic organisms	Duration of infection	Clinical symptoms
1	23-5-44	Nil	<i>Giardia lamblia</i> . <i>Trichomonas hominis</i> .	2 days	Diarrhoea, slight abdominal discomfort, not very ill.
2	9-6-44	Indefinite	Nil	12 days	Acute dysentery, great abdominal discomfort. Very ill. Stay in hospital 38 days.
3	10-7-44	Nil	Nil	1 day	Diarrhoea, bulky and frothy stool, slight abdominal discomfort. Not very ill.
4	2-8-44	Nil	<i>Ascaris</i> ova	2 days	Diarrhoea, slight abdominal discomfort, not very ill.
5	7-8-44	Indefinite	Nil	20 days	Acute dysentery, great abdominal discomfort, very ill, stay in hospital 26 days.
6	16-8-44	Indefinite	<i>Trichomonas hominis</i>	1 day	Mild dysentery, moderate abdominal discomfort. Not very ill. Stay in hospital 8 days.
7	28-8-44	Nil	<i>Ascaris</i> ova	2 days	Diarrhoea, moderate abdominal discomfort. Moderately ill.
8	29-8-44	Nil	<i>Ascaris</i> and ankylostome ova.	8 days	Diarrhoea, bulky, frothy stool. Moderate abdominal discomfort. Moderately ill.
9	1-9-44	Nil	Nil	1 day	Indigestion and very slight abdominal discomfort. Patient did not look ill at all.
10	5-9-44	Nil	<i>Ascaris</i> and ankylostome ova. <i>Trichomonas hominis</i> .	1 day	Diarrhoea, moderate abdominal discomfort. Moderately ill.
11	15-9-44	Nil	<i>E. histolytica</i> (vegetative).	1 day	Chronic diarrhoea, moderate abdominal discomfort. Moderately ill.
12	17-9-44	Nil	Nil	2 days	Diarrhoea, slight abdominal discomfort. Not very ill.
13	16-10-44	Nil	Nil	1 day	Mild diarrhoea. No abdominal discomfort. Patient did not look ill at all. Stay in hospital 2 days.
14	5-12-44	Nil	<i>Ascaris</i> and <i>Trichuris trichura</i> ova. <i>Trichomonas hominis</i> .	21 days	Diarrhoea, moderate abdominal discomfort. Moderately ill. Stay in hospital 21 days.

Conclusion.—

1. Fourteen cases in 7 months appear to be a high incidence in this area as compared with the figures reported from other areas.

2. All cases from the same area are suggestive of endemicity of the infection.

3. Practically all the cases were confined to the British troops which is suggestive of racial susceptibility.

4. Most of the cases occurred during monsoon suggesting a seasonal prevalence.

5. Though usually it is a mild infection without much distress, acute dysentery with prolonged illness is not uncommon.

INTRAPLEURAL PRESSURES IN CONGESTIVE HEART FAILURE

By P. N. LAHA

(Department of Medicine, Medical College, Agra)

THE present work consists of the measurement of intrapleural pressures in patients suffering from various degrees of congestive heart failure and the effect of digitalization on the same. The modified Lillingston and Pearson pneumothorax apparatus was used. The site chosen was the sixth space in the anterior axillary line either on the right or the left side. Diet, administration of digitalis, etc., were standard for each patient.

Results are tabulated below.

Conclusion

In congestive heart failure both the inspiratory and the expiratory intrapleural pressures are diminished in the majority of cases, the normal intrapleural pressures during inspiration

TABLE

Number	Name	Age, race and sex	Degree of heart failure	Intrapleural pressure in cm. water before digitalization			Response to digitalis	Intrapleural pressure in cm. water after digitalization		
					Mean				Mean	
1	B.	40, H.F.	++++	- 6,	+ 4	- 1	Good	- 11,	- 7	- 9
2	G.	26, H.M.	+++	- 7,	- 1	- 4		- 13,	- 5	- 9
3	S.	50, H.M.	+++	- 5,	0	- 2.5	L.B.D.

10	B.	50, H.M.	+++	- 8,	- 5	- 6.5	"	- 12,	- 4	- 8

++++ = Very severe.

+++ = Severe.

++ = Moderate.

+ = Slight.

H.M. = Hindu male.

H.F. = Hindu female.

M.M. = Muslim male.

M.F. = Muslim female.

L.B.D. = Left before digitalization.

Note.—The plus pressures during expiration were checked and confirmed after introducing 50 c.c. of air into the pleural space.

and expiration being —14 to —3 cm. water and —10 to 0 cm. water respectively (Laha, 1946). Clinical improvement after digitalization is associated with increase of these figures and vice versa. This can be explained by the fact that in congestive heart failure the lungs become oedematous which means they are less elastic. After digitalization the pulmonary oedema disappears or becomes less and with it the pressure increases. Correct explanation of the positive expiratory pressure in a few of the cases in the present series does not seem

to be available. The degree of heart failure is reflected in the range of intrapleural pressures.

Acknowledgments

My thanks are due to the Superintendent, Thomason Hospital, Agra, for his kind permission to publish the work. I must thank Dr. B. K. Dube, M.D., Lecturer in Therapeutics, Agra Medical College, for allowing me to study the cases of heart failure under him. I wish to express my appreciation of the services of the house physicians and the nursing staff.

A Mirror of Hospital Practice

RUPTURE OF THE UTERUS

By T. D. RAJOO, L.M.

Civil Surgeon, K. E. M. Hospital, Secunderabad, Deccan

CLIFFORD WHITE says that the rupture of the uterus falls into 3 main groups, occurring: (1) as an end result of obstructed labour, (2) as a result of injudicious operative midwifery, and (3) as a result of the yielding of a scar in the uterus. The first group, he says, arises from neglect of the patient and hence is rarely seen in civilized countries.

During the last 6 months 2 cases of rupture of the uterus due to obstructed labour and mis-handling by barber midwives were admitted into the hospital.

Case reports

Case 1.—A 2nd para, 28 years old, in labour for more than 24 hours, was admitted in a state of shock with anxious expression. Temperature 99.2°F. Pulse 120 p.m. Abdomen distended. Fœtal parts could be felt easily per abdomen and

the vertex at the vagina. The uterus could be palpated distinctly as a separate mass. Rupture of the uterus was diagnosed. After treating the patient for shock, the abdomen was opened with local anæsthesia supplemented with ether and oxygen. The fœtus and placenta with a fair amount of blood were found in the abdominal cavity. Though the head was in the vagina, the fœtus and placenta were removed without any difficulty. The blood in the peritoneal cavity was filtered, citrated and was given intravenously. There was a big complete tear of the uterus extending from the lower uterine segment to the body of the uterus. Sub-total hysterectomy was done. The patient stood the operation well. Before starting the operation the patient was put on 20,000 units penicillin three hourly and in all she had 8 lac units and 40 grammes of sulphadiazine by mouth. She had temperature for some days. The bladder was infected with *Bacillus coli*. She was discharged cured 5 weeks after admission. (1st delivery normal. Child died soon after birth.)

Case 2.—A fourth para, 30 years old, in labour for more than 24 hours was admitted in a state of collapse. Temperature 97.4°F. Pulse 128 p.m. Transverse presentation with hand and cord prolapsed. The other foetal parts could be felt easily per abdomen. A macerated male child weighing 5½ lb. was delivered easily by internal podalic version. Placenta was removed. The patient was put on glucose saline intravenously, 20,000 units penicillin three hourly, coramine and pituitrin four hourly. The following day—24 hours after admission—as her general condition had improved, the abdomen was opened under ether and oxygen. A big complete tear extending from the lower uterine segment to the body of the uterus was seen. Sub-total hysterectomy was done. After few days she developed lobar pneumonia on the right side and the bladder also was infected with *B. coli*. She was discharged cured 6 weeks after admission. The patient had 8 lacs of penicillin and 40 grammes of sulphadiazine. (Three deliveries normal. Two children died after some months.)

Penicillin is a great boon to cases of this type. Before penicillin days, the mortality rate was very high.

I am grateful to Col. M. P. Atkinson, I.M.S., for allowing me to report these two cases.

A CASE OF AMOEBIC PERICARDITIS

By J. M. F. D'MELLO
MAJOR, I.M.S.

Specialist in Pathology and Officer in-charge, Hospital Laboratory, CMH, Secunderabad

Rupture of an amoebic abscess of the liver into the pericardial cavity has been recorded on rare occasions. Two recent cases have been reported in the *Indian Medical Gazette* of July and August 1946, in which a definite pericarditis had been established by finding the *E. histolytica*. A similar case has come under my observation recently. The patient was admitted to hospital on 1st August, 1946, while he was on leave. He complained of diarrhoea and fever. He had been treated for dysentery about two months previously and once in 1940, but stated that he was never quite free from symptoms. He was an emaciated individual of 30 years of age. On examination a hard mass was palpated in the epigastric region extending from the right costal margin across the middle line to the left hypochondriac region. The left edge of this mass was sharp and fairly hard. His temperature on admission was 99°F., pulse rate was 120, and respiration rate was 22. Heart sounds were normal. The normal tympanitic note over Traube's area was absent. The lungs showed no abnormality. Examination of the stools revealed blood and mucus and numerous vegetative *Entamoeba histolytica*. The morning after admission the patient complained of giddiness and of pain in the sternal region, collapsed suddenly and died.

Autopsy findings

The body was that of an emaciated male of about 30 years of age. Rigor mortis was not present.

Neck and thorax

Lungs and pleura.—There was no pleural effusion. The right lung was almost completely adherent to the parietal pleura. Both lungs appeared normal.

Heart.—On opening the pericardial sac a purulent fluid resembling anchovy sauce welled out. About 6 oz. of pus were present. An aperture was found in the inferior surface of the sac and through this aperture the pus was entering. The aperture was 3 mm. in diameter. The epicardium showed small raised inflammatory areas. No definite ulceration was evident. The heart was not opened as it was decided to preserve the specimen *in toto* (see note under 'Liver').

Esophagus and trachea.—No abnormality was noted.

Abdomen.—No free fluid or pus was seen in the peritoneal cavity.

Liver.—This organ was larger than normal and its lower border was about three inches below the costal margin on the right side. The left lobe was found to consist of a large abscess cavity and its upper surface was completely adherent to the diaphragm. The pus had evacuated itself through the perforation into the pericardial sac during manipulation at the autopsy and hence the lower border of the left lobe was not apparent below the costal margin when the abdomen was opened, as the abscess cavity had collapsed. About 1½ pints of pus were collected from the liver abscess. The cut surface of the right lobe showed congestion.

Spleen was normal in size and showed no gross abnormality in its cut surface.

Kidneys.—Both were normal in size. The cut surface was very congested. Their capsules stripped easily.

Stomach.—No abnormality was seen.

Small intestine.—Mucosa appeared congested. No ulceration was seen.

Cæcum.—The whole cæcal wall was much thickened. The mucosa showed numerous deep punched-out ulcers covered over the yellowish sloughs.

Large intestine.—Numerous typical amoebic ulcers were present throughout its length right down to the sigmoid colon.

Other organs showed no gross abnormality.

Morbid histology

Liver.—Sections through the abscess wall showed a thick outer layer of connective tissue and an irregular layer of necrotic liver cells. *Entamoeba histolytica* were seen among the necrotic liver tissue and also in the connective tissue wall.

Cæcum.—A section through an ulcer showed an old amoebic infection. The submucosa was thickened and contained many *E. histolytica*.

Heart.—Muscle fibres adjacent to the epicardium showed cloudy swelling. The epicardium showed fibrinous flakes on its surface. The sub-epicardial area was infiltrated with mononuclear cells and showed a coagulative necrosis. *Entamoeba histolytica* were seen in this layer. A round cell infiltration was also evident in some places in the sub-epicardial layer but was not pronounced.

Commentary.—The cause of death was rupture of an amoebic abscess of the liver into the pericardial cavity. The interesting point is that there had been a leakage of amoebic pus into the pericardium for some days prior to death as was evidenced by the microscopic lesion of the epicardium—in other words an amoebic pericarditis had been established.

Acknowledgment

My thanks are due to the Director of Medical Services, G.H.Q., India, for permitting me to publish this report.

OXYTOCIC ACTION OF NEPTAL

By MAJOR C. V. KRISHNASWAMI, M.B., B.S.,
D.O.M.S. (Lond.), F.R.C.S. (Eng.)

S. H. P. Hospital, Shertally (Travancore)

A WOMAN, age 35, 6th para, 8 months, was admitted for general anasarca. She was intensely anæmic, conjunctiva pale as paper, earthy colour of skin, pitting œdema from face down to dorsum of feet, with some fluid in the abdomen, labia majora were like ovoid blisters and giving rise to great discomfort. There was a blowing murmur in all areas of cardiac region and distress in breathing.

She was given 2 c.c. of neptal intramuscularly at 6 p.m. on the second day of stay in hospital. At 7 p.m. she went into labour and at 10 p.m. was delivered of a male baby, puny and probably about 4 lb. in weight—no weighing machine available. She urinated profusely and by 9 a.m. next morning was so shrivelled up as to be unrecognizable. Mother and baby are well at the time of writing. Treatment for ankylostomiasis is being initiated.

The leaflet in the box of ampoules—the only literature at hand to consult—does not mention any action of this drug on the uterus and that is why this note is sent for publication to invite the attention of the profession to it, and confirm or refute my inference.

Therapeutic Notes

NOTES ON SOME REMEDIES

XV.—DRUGS IN SYPHILIS (contd.)

By R. N. CHAUDHURI, M.B. (Cal.), M.R.C.P. (Edin.),
T.D.D. (Wales), F.S.M.F. (Bengal)

Professor of Tropical Medicine, School of Tropical Medicine, Calcutta

III. Cardiovascular syphilis

SYPHILIS attacks the blood vessels after a long latent period, and then the brunt of the

attack falls on the aorta at its origin. It is a chronic inflammatory process of the vessel wall leading to dilatation and regurgitation or anginal attacks by implicating the mouths of the coronary arteries. In the past too energetic treatment with powerful remedies was the cause of rapid heart failure from the Herxheimer reaction or proved too toxic for the already damaged heart. In other cases it was followed by immediate clinical improvement and then by a downhill course ('therapeutic paradox') caused by rapid resolution of the syphilitic tissue with the resulting scarring and fibrosis of the aorta. Treatment should therefore be cautious, even in uncomplicated aortitis, with the insoluble bismuth and iodides, the doses being gradually increased according to tolerance. After three months of this treatment NAB may be started with a dose of 0.15 gm. gradually increased up to a maximum of 0.3 gm. If no unfavourable reaction occurs the arsenical course is completed with 10 or 12 injections. After an interval the patient requires another similar treatment and thereafter annually a course of bismuth followed by arsenic unless signs of heart failure develop. Provided that the disease is not advanced, its progress may be arrested by the above treatment. In aortic regurgitation it is most important to avoid any reaction. Acetylarsan is a convenient preparation for this condition, but in the U.S.A. bismarsen is more popular. No arsenic should be used in the presence of true angina, dyspnoea or congestive failure and in such cases it is better to use mercury instead. Penicillin is not recommended in cardio-vascular syphilis, as sufficient data are not yet available.

IV. Neuro-syphilis

Broadly speaking, there are two main types of lesions: (1) meningo-vascular, e.g. gummata, meningitis, vascular disease causing thrombosis, and meningo-myelitis, and (2) parenchymatous, in which the main changes are in the nerve cells and fibres and which includes tabes dorsalis and general paralysis of the insane. Neuro-syphilis may be asymptomatic when the only sign is an abnormal spinal fluid. Vascular lesions respond well to energetic treatment which is begun with bismuth (or mercury) and iodides followed after a month by NAB and bismuth for ten weeks. Four such courses are given in a year and thereafter depending on clinical and serological improvement the patient will probably require at least one course a year for several years as a safeguard against recurrence. In acute cases, e.g. severe meningitis, it is important to avoid intensive treatment and not to use arsenicals until the patient is under the influence of bismuth and iodide as this may lead to a reactionary increase of the syphilitic process.

In parenchymatous syphilis, damage to the nervous tissue beyond a certain point cannot be

made good and residual symptoms tend to persist even when the syphilitic process is burnt out. While favourable results may not be expected in more advanced cases, tryparsamide and bismuth may arrest deterioration and contribute to the prolongation of life when treatment is begun sufficiently early and continued over a long period. Courses of tryparsamide 30 gm. and bismuth 2 gm. are given four times in a year and iodides are given in the intervals. In assessing their value in *tabes dorsalis* it must be remembered that the natural progress of this disease is variable and it may undergo spontaneous arrest at any stage. In general paralysis pyrexial therapy is the most efficacious mode of treatment so far available. This may be achieved by infecting the patient with benign tertian malaria and allowing him to have up to 12 rigors before exhibiting quinine or by placing him in an apparatus in which he is electrically heated until a temperature of 104°F. and upwards is reached and maintained for 6 to 8 hours on ten occasions. The treatment is valuable in early cases but should be given only in an institution. After fever therapy the patient must be put on tryparsamide and bismuth.

Penicillin in neuro-syphilis

Experience of penicillin in neuro-syphilis is based mainly on the 'standard' course which consisted in giving altogether 2,400,000 units in 7½ days; it will probably have to be revised in view of the present tendency to use large dosage with or without arsenic and bismuth. Its effectiveness seems to depend on its ability to reach the diseased meninges, blood vessels and parenchyma and though it does not appear in the cerebrospinal fluid in significant quantity it exerts a favourable effect on it with regard to cell and protein contents. The Wassermann reaction of the fluid tends to become negative, but that of the blood remains unchanged especially in the parenchymatous forms. Before starting penicillin it is better to give a few injections of bismuth in view of the known risk of Herxheimer reaction. Best clinical results have been obtained in meningo-vascular syphilis but the late form which occurs long after infection often resists treatment. Both *tabes dorsalis* and general paralysis improve at first but the clinical and serological improvement is not maintained unless the treatment is followed by prolonged arsenic and bismuth in one case and malaria therapy in the other. Promising results have however been described in the U.S.A. following injections of penicillin alone but further time must elapse before these results can be finally assessed.

V. Syphilis in pregnancy

The clinical manifestations are often suppressed when the disease is acquired during pregnancy, no primary stage may be noted and

the secondary lesions are either slight or absent. This latency may persist for many years in spite of treatment.

Treatment should be energetic and repeated at each pregnancy whether the blood test is positive or negative. The drugs are well tolerated and can be administered up to the eighth month of pregnancy, but the doses of NAB and bismuth should be limited to 0.3 and 0.15 gm. respectively. With early and adequate treatment the prognosis is quite good. Penicillin will probably prove to be the drug of choice in this condition. As it passes through the placenta it may help in preventing congenital syphilis.

VI. Congenital syphilis

The infection occurs *in utero* in the latter half of pregnancy. The lesions are most often seen in the first six months but may appear in later childhood. The prognosis is good especially when treatment is begun in the first period, but interstitial keratitis is very resistant and neurological involvement is almost a hopeless condition. Treatment follows the same general line as in adults. As a rule children tolerate the drugs well, but as they are frequently debilitated, the dosage should be calculated according to weight rather than age. For severely affected or premature infants it is better to start with acetarsol by mouth or bismuth by injection. When acetarsol is used it is given daily in gradually increasing doses (from 0.005 to 0.020 gm. per kg. body weight) for ten weeks, and then the course is repeated three times with a four weeks' interval between each course. In less severely affected infants treatment may be commenced with sulpharsphenamine by intramuscular injection in doses of 0.01 gm. per kg. Whenever possible a change should be made over to neoarsphenamine. Bismuth is given either concurrently or alternately in doses of 0.005 mg. per kg. The inunction of mercury is of value, but less effective than bismuth. Iodides are not well tolerated in infancy.

The continuation of the treatment will depend on the local and general condition and a return of the Wassermann reaction to negative, but a minimum of two years' treatment is advised. The patient must be under observation for some years as relapses sometimes occur.

The immediate results of penicillin in congenital syphilis are very gratifying but the best methods of its use have not yet been satisfactorily settled. Reactions are frequent but mild and consist of fever and transient urticaria. The total dosage varies from 16,000 to 32,000 units per kg. body weight, but recently larger doses are being given. To avoid undue reactions some recommend a course of arsenic or bismuth for the first two weeks and then penicillin every three hours for five days.

Indian Medical Gazette

DECEMBER

AIR TRAVEL

Air lines are competing successfully with railways, as far as the higher income level traffic is concerned, in spite of occasional crashes. Such is the need for speed in the post-World War II days. (Incidentally, the expectation of life rose after the World War I and is bound to rise further after all the experiences of medicine, surgery and nutrition gained during the World War II have been incorporated in the daily routine of the citizens: There should be less need for hurry. The love of speed is partly a craze and partly an escape from the post-war discomfort of trains and ships. Be that as it may, air travel has come to stay like cocktails, night clubs and all the evils appertaining thereto. The number of new air fields—completed, under construction or under contemplation since 15th August, 1947—is astounding.)

Concerning the passenger.—Every air-minded passenger is not air worthy. Serious dangers arise from alteration in the atmospheric pressure and reduced oxygen pressure, and minor dangers from unaccustomed movements interfering with the body balance. A heavy aircraft provides a smooth motion and eliminates most of the difficulties of the unaccustomed motion.

The lack of air worthiness, due to the minor dangers, on the whole is lower than that of sea worthiness, if the excitement be excluded. The treatment of air sickness is the same as that of sea sickness. Subjects who are sea sick and car sick (while going uphill) are also air sick in a plane. Babies tolerate flying very well. Their bottle feeds may be prepared beforehand, carried chilled in a thermos flask and warmed in the plane when required.

The serious dangers arise from anoxæmia and pre-existing diseases. The anoxæmia gives rise to the *syncope of high altitude* (Hyman, 1947). Usually above 16,000 feet *altitude sickness*—tachycardia, tachypnoea, headache, lassitude, euphoria, nausea and vomiting—may occur. Syncope may supervene. Untreated syncope can kill. The pre-existing diseases deserve the attention of the family physician. They are: (1) Sinus and ear diseases. The infected sinuses may be emptied during ascent to be closed worse than before, afterwards. There may be a pain over the sinus and in the teeth, *aerodontalgia* (Shillito, 1947). Eustachian tubes may get congested if upper respiratory infection is present. Distortion of the drum of

the ear produces *aero-otitis*. Nasoconstrictor drug before and politization afterwards are useful. Chewing of gum and the associated swallowing movements during the flight are helpful. A person unable to swallow or an unconscious person may have serious damage done to the drum (Fulton, 1946). (2) Cardiac conditions. Ambulatory cases will not be affected much. Cases of angina will be affected by the concomitant hurry and worry of air travel. Patients who are unable to walk with comfort should not travel by air. Even the slight strain of 8,000 feet altitude may kill them. If they must travel oxygen must be provided. (3) Anæmia. Red blood count below 2.5 million is a contraindication. (4) Pulmonary conditions. Cases of asthma may give trouble if an attack occurs in the air. Diffuse fibrosis of lungs is serious only if it produces dyspnoea on slight exertion. Pneumothorax is a definite contraindication. Patients have died from displacement and distortion of the pericardium during ascent, from expansion of the air in the pleural sac. (5) Pregnancy. Until the last month a healthy woman is not affected much. (6) Disease of the nervous system. Mental patients are difficult everywhere. This difficulty is increased in the air. Cases of tabes should not be so carried that the unnatural movement interferes with their re-education in acquiring a sense of balance through vision. For this purpose air travel is to be preferred to a sea voyage because of its shorter duration. For professional aviation tabes is a bar (Ironsides and Batchelor, 1945). (7) Marked abnormalities of blood pressure.

Most of the difficulties of the reduced atmospheric pressure are eliminated in the 'pressurization' of the planes. In this process compressed air is discharged into the cabin to make up for the rarefaction of the air. So far only partial pressurization has been attempted by some air lines. When every plane is fully pressurized no patient will be barred. The Churchill egg illustrated in the daily press (Daily Press, 1948) was a pressurized cabin.

Concerning the staff.—The staff of the air lines are the responsibility of the 'flight surgeon' as the medical officers of the air lines are called (Bauer, 1943). Every employee of an air line is not air worthy. Every pilot, who of course is air worthy, is not capable of flight for more than a certain number of hours in a week. Flights give rise to symptoms which are the concern of aviation neuro-psychiatry. They may be a medico-legal problem at times. Medical men, other than flight surgeons, interested in such problems will find the necessary informations on regulations concerning the physical examination of the pilots, and their equipments and requirements.

In matters of physical fitness, equipment and requirement there is no comparison between the pilots and the passengers.

Concerning epidemiology.—Special precautions are necessary in excluding infected cases in the incubation period. So far yellow fever has been kept out of India by the vigilance of the public health authorities who do not allow any mosquitoes and uninoculated passenger from yellow fever zone to enter. Perhaps other influences are also at work : (1) The diseases may not thrive in India. There are many infectious diseases especially those of the nervous system which do not thrive in India. (2) The disease may be occurring in some other form, e.g. dengue fever. That the health department has succeeded 100 per cent in excluding a disease appears to be too good to be true.

Concerning special additions to the medical curriculum.—The textbooks include an account (Fulton, loc. cit.; Conybeare, 1946). The principles of physics, physiology and morbid anatomy, responsible for the discomforts and the dangers are simple and well known, so far as the passenger and his family physician are concerned. They will be treated like other new items in medicine by teachers in medical schools and colleges, and a place found for them. No specified special addition to the curriculum is necessary.

The 'flight surgeon' will learn his speciality as the military and naval surgeons learn their specialities. No responsibility rests on the medical schools and colleges. The over-burdened medical student's back should be spared the last straw.

These observations would not have been necessary had we not been asked recently to publish special communications stressing the need for additions to the medical curriculum. We have not published them because we do not approve of them. In fact we disapprove of them strongly.

INTERNATIONAL FORMS OF CERTIFICATES FOR VACCINATION AGAINST SMALLPOX AND INOCULATION AGAINST CHOLERA AND YELLOW FEVER

(Issued by the Office of the Director-General of Health Services, New Delhi)

ACCORDING to international requirements, certificates of inoculation and vaccination against cholera, smallpox, typhus and yellow fever must be in the internationally prescribed form. Copies of prescribed forms can be obtained from the nearest Administrative Medical Officer. These forms should be filled in by the passenger's doctor very carefully to see that all items have been accurately completed as any defective or

incomplete answers to the various items may result in the certificates not being recognized by the countries of transit and destination, and the passenger may, in consequence, be placed in quarantine. It is very important, for instance, to put in the 'origin and batch number' of vaccine used and in the case of smallpox vaccination to record the date and the result of inspection of vaccination in one of the terms prescribed at the bottom of the certificate. The prescribed forms also show the minimum and maximum validity periods of such certificates and passengers should ensure that their certificates are within the prescribed time limits.
 2. Considerable difficulty has been experienced recently by Indian passengers going abroad on account of their inoculation and vaccination certificates being

found defective by the countries of destination. It is therefore essential in the interest of the passengers themselves to see that they carry with them certificates on the prescribed forms which have been carefully completed by their doctors.

3. As regards certificates of inoculation against yellow fever, the medical profession and the public are hereby warned that on account of certain technical difficulties in the storage and administration of yellow fever vaccine, this vaccine is not available to the doctors or the public and the certificates cannot be issued in India by anyone except by the following 5 (five) Government centres of inoculation :—

- (1) Haffkine Institute, Bombay.
- (2) All-India Institute of Hygiene and Public Health, Calcutta.
- (3) King Institute of Preventive Medicine, Guindy, Madras.
- (4) Central Research Institute, Kasauli.
- (5) The Provincial Public Health Laboratory, New Delhi.

Vaccinations should be arranged, by appointment, with the nearest of these centres where internationally recognized certificates on the prescribed form will also be issued. The Government of India propose to take legal action against any unauthorized issue of yellow fever certificates. The medical profession are therefore warned not to issue yellow fever vaccination certificates under any circumstances whatsoever and to direct passengers requiring such certificates to one of the above-mentioned centres.

CERTIFICATE OF VACCINATION AGAINST SMALLPOX

THIS IS TO CERTIFY THAT..... (Age.....Sex.....) whose signature appears below has this day been vaccinated by me against smallpox.

Origin and batch number of vaccine.....
Official Stamp

Signature of Vaccinator.....

Official Position.....

Place.....Date.....

Signature of person vaccinated.

Home Address.

Important note.—In the case of primary vaccination the person vaccinated should be warned to report to a medical practitioner between the 8th and 14th day, in order that the result of the vaccination may be recorded on this certificate. In the case of re-vaccination the person should report within 48 hours for first inspection in order that any immune reaction which has developed may be recorded.

THIS IS TO CERTIFY THAT the above vaccination was inspected by me on the date(s) and with the result(s) shown hereunder :—

Date of Inspection.....Result.....

.....

.....

.....

Official Stamp

Signature of Doctor.....

Official Position.....

Place.....Date.....

Use one or other of the following terms in stating the result, viz, 'Reaction of immunity', 'Accelerated reaction (vaccinated)', 'Typical primary vaccinia'.

A certificate of 'No reaction' will not be accepted.

Signature of persons vaccinated.....

(This certificate is not valid for more than 3 years from the date of issue.)

Explanatory note regarding the interpretation of results of vaccination :—

(1) Reaction of immunity—A papule appears on the first day, does not develop into a vesicle and rapidly fades away.

(2) Accelerated reaction (vaccinoid)—A papule appears on the second day, a vesicle on the third day, pustule (if present) on the fourth day, scabbing starts on the fifth day and the scab is off by the eighth day.

(3) Typical primary vaccinia—A papule appears on the fourth day, becomes a vesicle on the fifth day and a pustule on the eighth day. Scabbing starts on the eleventh day, the scab is off between the sixteenth and twenty-first day.

CERTIFICATE OF INOCULATION AGAINST CHOLERA

THIS IS TO CERTIFY THAT..... (Age.....Sex.....) whose signature appears below was on the dates indicated inoculated against cholera.

MATERIAL INOCULATING OFFICER

Date

Origin Batch no. and type Signature Official title

.....
.....
.....

(Signature of person inoculated.)

Official Stamp of Inoculating Officer.

(Home Address).....Date....

(This certificate is not valid for more than 6 months from the date of issue.)

PRIZE OF THE INTERNATIONAL ASSOCIATION FOR PREVENTION OF BLINDNESS

An honorarium of 1,000 dollars to promote research work on ophthalmology is offered through the American Members of the Staff of the International Association for the Prevention of Blindness, the jury to consist of the Executive Committee together with the President and the Officers of the Association.

The award will be made in connection with the XVth Concilium Ophthalmologicum. Papers may be presented by any responsible research worker. The subject is to be *simple non-inflammatory glaucoma* and may include anything definitely relative to the question. The matter must be new and of such value, in the judgment of the jury, as to merit this recognition. Papers may be written in English or French; they should be those heretofore unpublished or those published between this date and 15th October, 1949. They should be in the hands of the Secretary of the International Association for the Prevention of Blindness, 66 Boulevard St. Michel, Paris, through whom they will reach the Members of the Judicial Committee, not later than 15th October, 1949.

The decision of the jury will be final.

MEDICAL STUDENTS TO WORK IN RURAL AREAS

(Abstracted from the editorial, *Medical Digest*, Vol. 15, No. 8, August 1947, p. 194)

THE senate of the Bombay University resolved at its recent meeting that with a view to acquainting the medical students with the problems and conditions of medical relief in rural areas, the Syndicate be requested to consider the desirability of requiring the medical students to work for a specific period, like six months, in rural areas as 'Interns'. An amendment that they should be asked to work as 'Interns' after passing the final examination and prior to receiving the degree was accepted. The mover of the resolution Dr. Mahajani said that he had already done some spadework with regard to the idea expressed in the resolution. A resolution moved by him in the Legislative Council had

been adopted and the Government had assured him of all the necessary facilities for the medical students to work in rural areas.

The idea behind the resolution, the supporters said, that the rural areas from where the poorer class of patients come to the big hospitals in large numbers will give the student a regular insight into social and preventive medicine which to-day is an absolute necessity. The Bombay Medical Council has also recently adopted a similar resolution.

NEED OF INTEGRATION OF PREVENTIVE AND CURATIVE MEASURES

(An abstract of the Convocation Address delivered by Dr. Jivraj N. Mehta, Secretary, Ministry of Health, and Director-General of Health Services, Government of India, at the College of Physicians and Surgeons, Bombay, on the 9th January, 1948)

'The objective of a national health programme should be to provide the individual with adequate curative and preventive medical facilities not in relation to his capacity to pay for such facilities but also in relation to the requirements of his physical and mental condition', observed Dr. Jivraj N. Mehta, Secretary, Ministry of Health and Director-General of Health Services, Government of India, in the course of his convocation address at the College of Physicians and Surgeons, Bombay, on 9th January.

He added: 'In establishing an efficient health organization, preventive and curative measures should be properly integrated and domiciliary and institutional services provided for the people should work in the closest possible co-operation. Our health programme should lay emphasis not only on disease and on methods of dealing with it, but it should also concern itself with the promotion of positive health'.

The implementation of the Bhore Committee's recommendations, Dr. Mehta said, would involve an expenditure of Rs. 1,000 crores in a period of 10 years. Though the financial resources of India at the present moment would not permit this expenditure for some time, we could not sit idly. The altered conditions demanded a reconsideration of the whole situation to enable the carrying out of necessary measures for medical relief and public health to meet conditions brought to the notice of the country in the Bhore Committee's report. Dr. Mehta, therefore, put forward a fourfold health programme which should make provision for (a) training of medical and ancillary personnel; (b) expansion of existing health services; (c) the promotion of medical research; and (d) education of the people to preserve their own health through the practice of personal and communal hygiene.

Training of personnel

Dealing with the training of medical and ancillary personnel, Dr. Mehta said that there was need for laying greater emphasis on the training of non-medical workers. These could, with adequate supervision by doctors, be made to perform a wide variety of curative and preventive duties in a well-organized health programme. Preventive inoculation, sterilization of water supplies, elimination of flies, mosquitoes and other insect pests were all measures which could be undertaken by persons with relatively small periods of training. This was all the more necessary because the cost of their training was relatively less than that required for medical education. With regard to medical education, it was desirable to raise the number of colleges, but the more urgent need was to raise the admissions to individual colleges, which could be done by providing a double shift of classes for laboratory subjects. For the clinical instruction of the additional students, Dr. Mehta suggested the idea of utilizing the existing hospitals in cities, where medical colleges exist, which were not so far utilized at present. Such an arrangement would facilitate quicker outturn of doctors per year at a relatively cheaper cost than by a further increase in the number of medical colleges in the country.

Expansion of health services

In attempting to expand the existing health services, Dr. Mehta observed, one of the steps necessary was the 'consolidating of the Medical and Public Health Departments in the provinces into a single organization so that the fullest possible measure of co-operation between the two branches of health administration may be secured. Without such co-operation it is not possible to develop reasonably good services in many fields, for example, maternity and child welfare work, control of infectious diseases, including tuberculosis and venereal diseases and supervision of health of school children'.

Dr. Mehta suggested for the consideration of the Provincial Governments that an organization be set up to carry expert medical advice to the remoter areas in a district which would be the unit of health administration. A mobile team consisting of a well-qualified physician, a surgeon, a gynaecologist, an obstetrician, an ophthalmologist, an aural surgeon and a clinical pathologist should be organized for service in two adjoining districts in the first instance, its range of jurisdiction being reduced later to a single district. This scheme will have the merit of bringing expert medical relief near the doors of the rural population which forms such an overwhelming part of the inhabitants of the country. Such a mobile team could visit selected centres in the districts where temporary hospitals, say tents provided for the purpose, could be housed, and these mobile hospitals could be shifted from centre to centre in the districts every few weeks, so as to bring specialized medical relief to remote village areas as far as possible.

'In view of acute shortage of steel and cement so essential for construction of permanent hospital structures, we should concentrate on constructing 30-bedded Primary Health Centres or small Dispensary Hospitals, about 2,500 of which would be needed for the whole country to meet the short-term programme recommended by the Bhore Committee, in different parts of the country, and such centres including the houses for the medical, nursing and other staff, should be constructed of sun-dried bricks rendered with mud plaster like the other village buildings in the north of the country; and in the other parts of the country such structures may mainly consist of balties, bamboos and chhattis with tiled or thatched roof. It is readily understandable that we cannot obtain a hygienic finish in such buildings, but where this is required as in the case of operation theatres and treatment rooms, burnt bricks may be utilized and stone pavement for flooring wherever stone may be easily available. Thus, if Primary Health Centres could be constructed out of local materials available in rural areas, and if the assistance of the village people is sought in constructing them, the cost of construction would be considerably reduced and the recommendations of the Bhore Committee for extended medical relief more speedily put into effect than is otherwise possible'. Such structures would last 10 to 15 years by which time Dr. Mehta hoped it might be possible to put the long-term programme of the Bhore Committee recommendations into effect.

Dr. Mehta expressed the opinion that the services of practitioners of indigenous systems of medicine could be utilized for a wide variety of functions, particularly in the preventive field, with adequate training given to them either as part of their curriculum or at a later stage before admission to public service.

Medical research

Dealing with the problem of medical research, Dr. Mehta proposed whether a small cess on drugs and medical appliances entering the country from abroad could not be imposed statutorily in order to provide an annual source of income for the Indian Research Fund Association, the premier organization for the promotion of medical research in the country. He also suggested that apart from the Central Government, Provinces should also contribute their share to the cause of medical research.

Health education

Health education, Dr. Mehta observed, was a subject of great importance. It could not, in his opinion, be divorced from general education, which included the training which the individual began to acquire at home from the early period of his life as well as the training he received at his school and in later life. The health education programme should be so extensive as to influence the individual through every stage of his life. Even so, infancy and childhood were the periods during which the individual's main habits were formed and the health education programme should concentrate on the teaching of the parents, particularly the mother, to impart proper training to their children as well as on the teachers who could influence materially the formation of habits in children at an impressionable age. He felt that health education could produce its most lasting effects if it were grafted on to general education both for children and adults.

SPEEDING UP THE TRAINING OF NURSES

TWO-YEAR COURSE PROPOSED

By RANDOLPH B. JONES

(Issued by British Information Services, Eastern House, Mansingh Road, New Delhi)

To speed up the training of nurses in Britain, a Working Party set up by the Ministry of Health has suggested a two-year course instead of the usual three-year training period. The article below, which outlines the salient features of the scheme, is of special interest to India where the shortage of trained nurses is acute and where plans have already been formulated for the setting up of a General Nursing Council to co-ordinate the activities of the provincial bodies and to prescribe a uniform standard for the profession.

In a report, which was described by Britain's Minister of Health, Mr. Aneurin Bevan, as the 'most stimulating and challenging document yet produced on nursing', a Working Party which had been set up by the Ministry in January 1946, has laid down a number of suggestions for a fundamental reform of the training of nurses in Britain.

As the main recommendations of the report are all long-term measures and ask for considerable changes of organization, the Ministry of Health will consider, of course, the views of the nursing profession before taking any final decisions on them. However, while these long-term reforms are being worked out, the Minister has already set up some plans for immediate action to make the best use of the existing nursing force in Britain.

Student status

One of the principal recommendations of the Working Party is to give all nurses in Britain the full status of students during the period of their training and to relieve them of all domestic duties in hospitals.

The report suggests that under these conditions the nurses' training course might be shortened from three to two years without lowering the standards of British nursing. During this period trainees could be systematically introduced to all spheres of their profession. The curriculum would not only embrace all sides of hospital nursing, but also public health service and the prevention of disease.

To give students the chance of practical experience in all aspects of their profession, it is recommended to form composite training units covering the entire range of nursing, such as hospitals, clinics and public health institutions. This would give them a chance of moving in turn from one aspect to another.

The new two years' course for nurses as set up in this report allows 18 months for the general basic part of the training. After passing a preliminary examination, students should then be able to take part in a six months' concentrated course in a specialized field. At the end of this time they would take their

final examination and be certified provisionally as 'State Registered Nurses'.

To conclude the period of their training the State Registered Nurses, however, would be compelled to have a year's practical experience under supervision before being allowed to practise their profession independently. That way the Working Party hopes to answer criticism that a two-years' course may be insufficient for thorough training. If any nurse should wish to change over into some other branch of her profession she would have to attend another six months' specialized course.

Selection methods

Further courses could be arranged in universities and schooling centres to allow selected nurses to prepare themselves for higher posts in hospitals. A more psychological approach to the selection of candidates for these posts is recommended.

During World War II the Service Departments had worked out a number of psychological selection methods for the forces which proved their worth so conclusively that they are adopted at present for selection in civilian occupations. If adapted and used for nurses they would permit an objective choice to be made among nurses before they begin their training. Such selection methods would also give a clear picture of the abilities of candidates for the higher posts such as ward sisters or matrons.

Close examination has shown that over half the student nurses (54 per cent) left the profession during their training. Many of them appeared unsuited to their work intellectually or temperamentally—they should never have been admitted to the courses. Many girls had chosen the profession out of an inspiration to succour suffering humanity. But instead of tending the sick or helping the oppressed, they found themselves given futile or subordinate tasks which should have been performed by the domestic rather than the nursing staff. Senior nurses should give more consideration to the temperament of their juniors.

The Working Party conclude that the wastage of nurses could be reduced to 15 per cent if modern methods of selection and training were adopted.

Reforms in hospitals

The report recommends a number of reforms in the hospitals such as the introduction of the three-shift system, increased leisure and regular holidays for nurses and improvement of material conditions in living quarters. Part-time nurses should be encouraged, so that married nurses, in spite of their domestic duties, could practise their profession. The increased use of male nurses would help to relieve the present shortage of staff. Candidates for training, who are below the required level of abilities for nurses but otherwise suitable, should be used as nursing orderlies.

A full implementation of all these recommendations would ask for a considerably stronger nursing force than is at present available; 112,000 instead of 88,000 nurses are needed to make the three-shift system and the reform of training possible. In future, once the National Health Service has come into being, Britain might need between 120,000 and 125,000 nurses. The present general labour shortage naturally restricts the recruitment of nurses. A further difficulty lies in finding an adequate number of teachers and instructors for the revised training system.

The Ministry of Health has asked hospital authorities to examine interim measures to reduce wastage, to build up their domestic staffs to relieve nurses of such duties and to make the maximum use of part-time and married nurses. In recent months 12,600 nursing staff have taken up part-time service. As a result, hospitals in different parts of Britain have been able to re-open wards. Three thousand European volunteer workers have increased the domestic staffs in the hospitals.

Such reforms can thus be introduced, but the more fundamental recommendations of the Working Party require an organization which can only be gradually set up.

Public Health Section

ROLE OF *PALKIES* (MOVING RELIGIOUS FAIRS) IN THE EPIDEMIOLOGY OF CHOLERA WITH SPECIAL REFERENCE TO SRI EKNATH MAHARAJ *PALKI*

By S. RAGHAVENDER RAO, L.M. & S. (Hyd.), D.T.M.,
D.P.H., D.Sc. (Cal.)

Bureau of Epidemiology, Public Health Department,
Hyderabad-Deccan

THE important part which religious fairs and festivals play in the spread of cholera has been discussed in all its aspects by the public health authorities from time to time. As a result of this, the preventive measures adopted among the pilgrims such as indirect form of compulsory anti-cholera inoculation by the prohibition of entry of uninoculated persons into festival areas and efficient sanitary arrangements at the festival centres themselves have reduced the incidence of cholera in the country to a large extent.

In this article it is intended to deal with and discuss a type of moving fair which is locally known as a *palki*, literally meaning a palanquin intended for carrying an idol or a deity or an important person in procession, but in this particular case used or intended for carrying the wooden sandals of some well-known saint to a central place of pilgrimage, such as Pandharpur in Bombay Presidency. These *palkies* start from a place which is either the birthplace of a saint or where his ashes lie buried. They sometimes travel a distance of more than three to four hundred miles before they reach Pandharpur and after attending the Ashadi fair there during the month of July, return to their place of origin.

These *palkies* serve also another useful purpose. Several poor pilgrims who are unable to finance a long journey to Pandharpur follow the *palki* on foot in easy stages, and are also fed on their way by the devotees of the saint. In olden days when a long journey was not free from risk to life and property, such travelling in a body (consisting of thousands of pilgrims) avoided this danger. On the other hand till recently these *palkies* were usually a source of cholera at Pandharpur or they were the means of carrying the infection from Pandharpur to hitherto uninfected villages along their return route. In spite of the greater facilities afforded by the railway and motor services, during the present times, many of the pilgrims still find this way of pilgrimage to Pandharpur by following a *palki* a great advantage.

During recent years public health authorities have become alive to this source of spread of cholera epidemics, and arrangements are made

along the routes for thorough disinfection of drinking water supplies and attention to other necessary sanitary measures. Now these measures, combined with compulsory inoculation of pilgrims, do help in preventing the spread of infection. For example, a *palki* had to start with a large number of pilgrims from a place which was already heavily infected with cholera and there was infection in some of villages along the route. Even among the pilgrims a few cases of cholera had taken place but an epidemic outbreak was prevented and none of the hitherto uninfected villages were affected as a result of the procession which covered a distance of more than 300 miles.

Origin of the *palki*

In the history of the Deccan the town of Patan (formerly known as Paithan), the headquarters of the taluka of the same name in the district of Aurangabad, has played a great part. It is mentioned in the old religious books of the Hindus and not a few of the Greek authors have referred to it in their works. However, the present-day importance of this town is due to the fact that it was the birthplace of the great Maratha saint, philosopher and poet, Eknath. Like his parents and grand-parents, Eknath was a great devotee of the presiding deity at Pandharpur. He used to visit the place almost annually. Eknath died in the year A.D. 1599 and his ashes were buried on the banks of the river Godavari on the outskirts of the town Patan.

Since his death it has become customary to take the *padukas* (wooden sandals) in a *palki* every year to Pandharpur during the Ashadi festival. The *palki* starts from Eknath Maharaja's temple at Patan and the tradition states that it takes the same route to Pandharpur as was taken by the saint himself when he was alive.

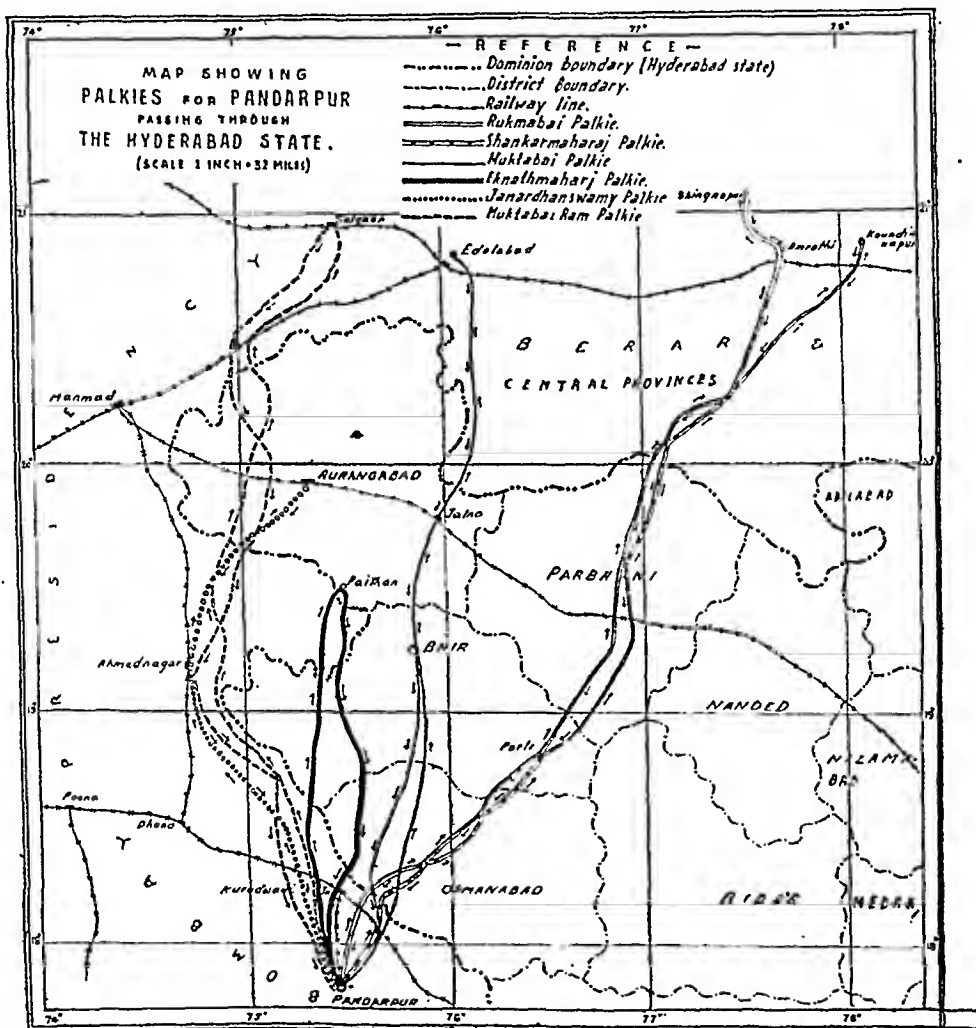

During the year under discussion, the *palki* left Patan on 16th June, 1941, and reached Parenda, the last halting place within H.E.H. the Nizam's Dominions on 28th, a distance of about 150 miles. A further six days' journey brought it to Pandharpur, about 55 miles from Parenda. On its return journey the *palki* left Pandharpur on 8th July and reached its first halting place within the Dominions on the 13th. With a greater speed on its return journey, crossing the river Godavari, it reached Patan on the evening of 20th.

The author was in charge of the medical and sanitary arrangements and followed the *palki* only within the limits of H.E.H. the Nizam's Dominions, in which the major part of both outward and return routes lay.

Medical help

Besides the treatment of cholera cases and the adoption of preventive measures at every halt within the Dominions (and not infrequently at other places when needed), a well-equipped dispensary was always at the disposal of the pilgrims for attention to all ailments. This proved not only very popular but helped to create confidence in the authorities whose advice, particularly with regard to health matters, was willingly followed by the pilgrims. But for this ready co-operation, cholera epidemic would

people who generally do not exceed 50 to 100 in number; get a little better quality of food. In most of the villages it is the custom to prepare bread in separate houses and then to collect them at a central place not far off from where the *palki* stops. All the pilgrims are collected at this place and fed. Where a sweet preparation is provided, it is generally prepared in one place, materials being collected from different houses previously. In a few towns on the way the individual villagers take a number of pilgrims to their houses and feed them. Wherever food

Map showing palkies for Pandarpur passing through the Hyderabad State (scale 1 inch=32 miles).

have most probably created a havoc among the pilgrims and spread to the villages on the route.

Feeding arrangements for the pilgrims en route

The usual custom is that all the pilgrims are fed by the residents of the village where the *palki* stops. As the places of halting are almost fixed, the villagers make arrangements in advance. Most of the pilgrims are usually given jawari or bajri, bread and dal, and where the villagers are more well-to-do, some sweet preparations are also supplied. Brahmins and other higher caste

was prepared in a general kitchen it was supervised and only fresh materials were allowed to be used and apparently healthy persons permitted to prepare them. All the wells in the villages were disinfected by the health inspectors 24 hours in advance besides the previous disinfection by the health staff of the district generally a week earlier. In places where cholera epidemic was feared or where cases were actually occurring, all suspected wells were kept out of bounds to the pilgrims and the water of other wells in the village once again disinfected. No pilgrims were allowed to drink water that was not previously permanganated or treated

with bleaching powder. Wherever possible, eating and drinking in infected villages was avoided entirely.

Cholera infection and the anti-cholera measures adopted

Patan town, from which this *palki* started on 16th June, was already in the grip of a cholera epidemic. From 23rd May, when the first cholera case was reported, up to the time of the author's arrival there (12th June) altogether 49 cases of cholera had occurred with 18 deaths. Cases had also been reported a few days earlier from the villages along the banks of the river upstream. With the help of the local officials, the teachers and students of the local school a watch was kept along the bank of the river to prevent washing of the clothes and at the same time to permanganate all the water that was taken from the river either for drinking or for other domestic purposes. Water along the edge of the river (one yard from the bank) was treated with bleaching powder twice a day for three days in succession, and the results were very encouraging. From the third day onwards no fresh case was reported. In the meantime special attention was paid to the pilgrims, who were pouring in numbers from the surrounding villages with the intention of accompanying the *palki* to Pandharpur on foot. All those who were not inoculated against cholera in one or other inoculating centres specially set up for this purpose, were inoculated. Pamphlets in Marathi, describing briefly the simple anti-cholera measures, were distributed freely. All the places particularly in H.E.H. the Nizam's Dominions, where the *palki* was scheduled to stop either for day meals or for night rest, were attended to by one or other members of the health staff of the district concerned, a week before by disinfecting all sources of drinking water supply. A health sub-inspector was always a day's journey ahead to attend again to the disinfection of the water supplies and to send information of any cholera infection present in the villages *en route*. However, these arrangements were not attended to on the second day for some reason or other at Mungi, a village in Ahmednagar district, on the south bank of the river Godavari. The first case of cholera among the pilgrims was detected at Kundal Pargaon, a place of night halt on the third day of the journey; immediately the health authorities of the district were informed of the incidence and the patient isolated and treated in a shed on the outskirts of the village. Early next morning before the starting of the *palki* on its onward march, all those pilgrims who had escaped inoculation at Patan or who had joined the procession on previous night from the surrounding villages were inoculated.

On the morning of the 20th June, information was received that Dahiwandi (population 125), a village in Bhir district which was on the route, was heavily infected with cholera (30

attacks and 14 deaths). First precaution adopted was that the *palki* was made to go through the outskirts of the villages instead of through it. All food and water distribution to the pilgrims from this village was stopped entirely.

The village Sirur (Ahmednagar district) was the next halt and here also similar measures were adopted by the local authorities.

On 22nd June, 1941, at Patoda, a boy was found to be suffering from cholera. He and the contacts (4 in number) were immediately isolated in a building outside the village but near the civil dispensary, and the medical officer of Patoda was requested to look after them; unfortunately the boy succumbed early next morning. Due to this incident, with the help of the local police and the medical officer, arrangements were made for establishing an inoculating centre outside Patoda village at a place through which the *palki* had to pass. Here the inoculation certificates of all pilgrims were carefully checked and all those who had joined the *palki* on the previous day in the intermediate villages and who were unprotected were given anti-cholera inoculation. By this time the number of the pilgrims was more than 1,500.

On the 23rd another case of cholera among the pilgrims along with 4 contacts was seen and isolated at Gumre-Pargaon. This patient recovered and so also another patient who was detected at Dighul, a British India village.

On the 25th the last case of cholera among the pilgrims was isolated at Deogaon, a village in Osmanabad district. The district health officer was immediately informed of this. From here to Parenda the journey was uneventful. On the morning of the 28th, on the eastern bank of the river Sina, in the presence of the Epidemic Officer of Ahmednagar, a careful scrutiny was made of the pilgrims and all those (only few in number, being the fresh arrivals) who were found without certificates were given anti-cholera inoculations. It was also assured that no cholera or contact case passed into the British territory and among the 1,697 pilgrims that accompanied the *palki* on that particular day. I was informed later by the Epidemic Officer of the Ahmednagar district that no case of cholera was reported among the pilgrims till it reached Pandharpur on 4th July.

On the return journey I met on 13th July at Karmala the pilgrims who were now nearly 1,100 in number. From here they entered the state limits at Halgaon. There was no cholera infection, but dysentery was rampant. All the patients were immediately brought under treatment and special attention was paid to the supervision of their feeding by trying to avoid chillies and hot spices in their food. To the more acute patients milk was provided with the help of the *palki* manager and some of the more charitably disposed villagers. Being previously informed that Southada village on the route was

heavily infected with cholera, I left the *palki* at Halgaon and proceeded straight to this place. Here 57 deaths had occurred during the preceding two or three weeks and at the time of my visit there were two patients with acute cholera symptoms. As the *palki* was programmed to visit the villages next morning at 9 a.m. and pilgrims to receive their morning meals in the village, I tried to persuade the Police Patel (the headman of the village) to avoid preparing food in the individual houses, but to collect the raw materials and to prepare it outside the village at some suitable place and feed the pilgrims there. The health staff promised to undertake the supervision of the preparation of food and the disinfection of all drinking water, so as to avoid all risks of infection. At the instigation of some ignorant leaders, the villagers insisted on preparing food for the use of the pilgrims in their own houses, many of which had still convalescents from the recent cholera epidemic. Under these circumstances the *palki* manager was successfully persuaded to halt outside the village instead of in it and all the pilgrims were persuaded not to partake any food at Southada. Having full confidence in the medical and sanitary arrangements made for them hitherto, they willingly walked to the next village on the route to have their food. In the evening there was halt at Dongarkini, a British India village, in which a suspected case of cholera had been found on the previous day. From here some of the pilgrims went to their respective villages in the neighbourhood, when only about 700 pilgrims were left in the procession.

On the 18th July, 1941, having obtained the information that a British India village, Antarvelli (quite near to the State border), was infected with cholera, I visited it and having really found it so, persuaded the *palki* manager to avoid this village altogether if possible. I believe the local authorities also desired the same and ultimately the procession passed through another village a mile away from the infected one. On the 19th by 5 p.m. it reached Patan with nearly 650 pilgrims, all in good health and, what is more, in cheerful spirits.

Total number of patients (new and old) treated was 821 (see table). Majority of these patients were from the pilgrims, while a few, particularly cholera cases, were also from the infected villages on the route. Both on the outward and return journey the largest number of cases treated were those due to disorders of the digestive system. Malarial attacks were of greater frequency during the return journey and so also dysentery. Cholera was of course more prevalent during the outward journey and entirely absent during the return journey. The two cases, shown in the table during the return journey, were belonged to one of the infected villages. The main predisposing cause for the greater prevalence of the diseases of respiratory and digestive system and specific infections such as dysentery and malaria was obviously the

lowered vitality caused by the long journey on foot and other hardships endured by the pilgrims en route.

TABLE

New and old patients treated during the *palki* tour of Sri Eknath Maharaj of Patan in the year 1941

Diseases treated	Number of patients treated during the outward journey	Number of patients treated during the return journey	Total
Cholera	54	2	56
Malaria	48	90	138
Mumps	1	4	5
Gonorrhoea	1	6	7
Influenza	4	7	11
Dysentery (amoebic-clinical) ..	9	36	45
Pneumonia	4	4
Pyrexia of unknown origin	3	3
Diarrhoea	6	8	14
Diseases of the digestive system ..	82	89	171
Diseases of the respiratory system ..	18	56	74
Diseases due to intestinal parasites ..	13	1	14
Diseases of the nervous system ..	6	3	9
Diseases of generative system ..	3	..	3
Diseases of urinary system ..	2	4	6
Diseases of heart	2	..	2
Diseases of skin	66	52	118
Syphilis	4	3	7
Diseases of liver	4	8	12
Diseases of the ear	6	5	11
Diseases of the eye	4	11	15
Rheumatism	8	4	12
Injuries	26	19	45
Simple inflammation	3	2	5
Abscesses	11	2	13
Ulcers	10	3	13
Other diseases	7	1	8
TOTAL	398	423	821

Discussion

Though the important part played in the epidemiology of cholera by the fairs and festivals with large congregations has been long recognized, yet if epidemics are to be prevented or controlled, it is well to remember that better sanitary arrangements themselves will not afford complete protection or prevent its spread to the neighbouring provinces and states. Pilgrims travelling long distances, particularly those following important *palkies*, such as the one described above, to and from centres of pilgrimage, too often form the means of transmission of infection along their route and under favourable circumstances become the source of

epidemic outbreaks in the districts through which they pass. The villages through which the pilgrims pass have little or no provision of good and protected water supply nor any conservancy arrangements. The lanes and bye-lanes of a village which has been the night halt of a *palki* and its accompanying pilgrims form a repulsive sight next morning on account of indiscriminate use of these places as temporary latrines by the pilgrims. Under these circumstances, no wonder that an infection among the pilgrims is soon likely to be the cause of severe cholera epidemics not only among themselves but also in the areas through which they pass.

For a long time anti-cholera inoculation was followed on a voluntary basis but in many places response from the public and particularly from the pilgrims was not encouraging. The deliberations of the Central Advisory Board of Health at its second meeting held in Madras in 1938 gave an impetus to this question and at present some provinces and states do adopt the indirect compulsory inoculation method with very encouraging results. In Pandharpur in Bombay Presidency and in several important fairs and festivals in Hyderabad State, this method is adopted and it is the experience of the public health authorities in these places that opposition to inoculation is gradually dying out, and cholera inoculation is taken by the general public almost as a routine procedure before going to a place of pilgrimage.

Sanitary arrangements at fairs and festivals generally are the responsibility of the municipalities or district boards concerned, but in any way it is one single administration that has to deal with such matters. The *palkies* under discussion have to pass through more than one administration, as several of these *palkies* have their origin in Central Provinces and Berar and pass through more than two or three districts in the Hyderabad State and then through the districts of Ahmednagar and Sholapur in Bombay Presidency. For good managements and efficient sanitary arrangements, a close co-operation between the public and the health administrations of the different provinces and states concerned is necessary. Such an arrangement exists at least between Hyderabad and Bombay Presidency, and information of any cholera infection is immediately telegraphed to the Directors of Public Health of both Governments as well as to the district health officers of the districts through which the infected *palki* has to pass.

Whenever cholera breaks out in a pilgrimage procession, which is moving on foot at a fast speed and has a long distance to travel, the management of a cholera case becomes a difficult problem. This is particularly so when the route does not lie along the railway or roads but along cart-tracks. The patient, if left behind, will be without proper medical aid and it is also not possible to carry the patients and their contacts along with this large procession without risk to the others. It is always advisable to have one

or two bullock carts to serve as improvised ambulances, so that the patients and their contacts can be immediately isolated and sent to the nearest hospital or dispensary to be properly attended to.

There is no doubt that in this particular *palki*, which started from a place which was having a severe cholera epidemic and with few infected villages along the route, it is this protection of the pilgrims by mass anti-cholera inoculation that prevented a severe outbreak among the pilgrims themselves and also prevented the infection from spreading to hitherto uninfected villages that were on the route and which formed the places of day and night halts for a large number of pilgrims.

Summary and conclusion

1. A type of moving religious fair (*palki*) has been described. These processions passing to and from important places of pilgrimage have been the cause of spread of cholera in the past.

2. These *palkies* travel a long distance, sometimes more than 300 miles and pass through different administrations, making their management particularly very difficult when there is an epidemic of cholera outbreak, unless very close co-operation exists between the public health departments of the different administrations.

3. Sri Eknath Maharaj *palki* in the year 1941 started from Patan, a town heavily infected with cholera, and its route lay through the area in which some villages were already affected.

4. As a result of adoption of compulsory (indirect) inoculation against cholera among the pilgrims, this *palki* did not witness any severe outbreak of cholera among its own followers nor was any of the hitherto uninfected villages on the route affected as a result of the procession.

5. Suggestions have been made to select with care villages that serve as night halts and also for the provision of bullock carts which can be improvised as ambulances to shift the cases to the nearest dispensary or hospital where they can be attended to.

In conclusion, I have to mention that without the active co-operation and help of the district health officers of Aurangabad, Bhair and Osmanabad districts and their staff, it would not have been possible for me to manage the cholera infection successfully.

A PLEA FOR WATER POLLUTION RESEARCH

By T. R. BHASKARAN, D.Sc. (Madras),
S.M. (San. Eng., Harvard), A.R.I.C., A.I.L.S.C.

(Assistant Professor of Sanitary Engineering, All-India
Institute of Hygiene and Public Health, Calcutta)

A LARGE proportion of the population in India still do not have an adequate supply of safe water and mortality due to water-borne epidemics is high. While other countries in the world have expert committees and centralized

research laboratories to administer their needs in regard to providing safe water and abatement of water pollution, we have not even made a beginning in this direction.

India is now on the threshold of a new era and many plans are afoot for her future scientific development. The Board of Scientific and Industrial Research is to expand its activities on a grand scale and many National Research Laboratories are being established. The Bhore Committee has made a very comprehensive plan to take care of the health of the nation. These plans, however, do not envisage immediate creation of any centre for research on water, sewage, industrial wastes and stream pollution. Establishment of Central and Provincial Water Boards have been considered in the Bhore plan but sufficient emphasis has not been placed on research as the mainstay of the Board's activities. There is no nucleus of water pollution research at the centre now. The facilities available in the small number of provincial and state public health laboratories are indeed meagre both in regard to men and equipment and hardly adequate to cope with routine work. Modern trends in public health engineering are unknown in the existing engineering colleges in India and they have very limited facilities for conducting investigations in this field.

Let us examine the status of water pollution research in other countries. Water pollution research is primarily the function of the Federal and State Health Services in the United States of America where most of the recent developments in this field have taken place. In England, it is part of the activities of the Council of Scientific and Industrial Research. Judging from the results achieved the developments in U.S.A. have been more fruitful both in regard to the advancement of knowledge in this field and providing better sanitation.

As early as 1913, an Act of the Congress empowered the United States Public Health Service to extend its activities to investigations of stream pollution and other allied sanitation problems. In July the same year the Service opened a laboratory at Cincinnati (Ohio), which was devoted exclusively to the study of streams used for water supplies in regard to pollution by wastes and their natural and artificial purification. A well-balanced team of experts in Sanitary Engineering, Chemistry, Bacteriology and Biology was stationed in this laboratory. During the last 30 years a large volume of very useful work has been carried out at this station. Apart from solving the immediate problems on hand a great deal of fundamental work on problems of self-purification of streams and lakes, sewage oxidation and water treatment have also been carried out; general laws have been formulated in regard to natural purification under various conditions of pollution load, stream flow and temperature. A variety of sanitation problems have been investigated with most fruitful results and it is hardly possible to

review them here. Suffice it to say, the publications from Cincinnati Laboratory have ranked very high in the world's literature on the subject and many of them are used in the teaching of Public Health Engineering all over the world. Reviewing twenty-five years' activities of the Cincinnati Laboratory the Medical Director of the United States Public Health Service says in 1938 that 'the activities of this laboratory have constituted one of the best investments of not only the Public Health Service but of the Nation'.

Among the State Health Laboratories of America, that have made significant contribution, mention may be made of the Lawrence Experiment Station. This was established as early as 1887 by the Massachusetts State Board of Health in order to carry out an act of the legislature to protect the purity of inland waters. One section of this act authorized the Board 'to conduct experiments, to determine the best practicable methods of purification of drainage and sewage or disposal of the same and to employ such expert assistance as was necessary'. The contributions made by the Lawrence Experiment Station have laid the foundations of some aspects of modern sanitary engineering. Allen Hazen's fundamental investigations on filtration and Sedgwick's work on water microscopy were carried out from this station. Experiments carried out at Lawrence as early as 1912 formed the basis for what is now known as the activated sludge process of sewage treatment. Apart from these, much useful work on trickling filters and treatment of trade wastes have also been carried out in recent years. The achievements of Lawrence and Cincinnati gave the necessary incentive for a nation-wide development in water pollution research in America and to-day every one of the State Health Departments has a team of experts and well-equipped laboratories to investigate their water, sewage and trade waste disposal problems.

In the early days, County and Municipal Drainage Board and their laboratories carried out much useful work on water pollution problems in England. The Royal Commission on Sewage Disposal and more recently the River Boards have made very notable contributions—some of their data and findings are even to-day considered classic in this field of studies. It was not until 1927 that the Water Pollution Research Board was established in England. Its terms of reference were as follows: 'To report to the Privy Council for Scientific and Industrial Research from time to time, schemes for research on pollution of rivers and other sources of water supply by industrial effluents and sewage and on any relevant matters affecting purity of inland waters and to supervise execution of approved investigations'. Simultaneously with the formation of Board an organization for research was also set up as part of the activities of Department of Scientific and Industrial Research. During the last two decades the Board has carried

out many useful investigations on treatment of water; sewage and trade wastes, effects of pollution of surface waters and allied problems. During the last war, when there were great changes in the industries of the country, the Board has tackled successfully in their laboratory many serious problems of pollution of surface water by industrial wastes.

America is more advanced than England in the application of newer knowledge to water treatment, sewage purification and abatement of pollution. English practices have lagged behind theory and old-fashioned treatment plants operated on empirical basis are not uncommon in England to-day. One of the factors responsible for this state of affairs is that organized research was encouraged in America much earlier and on a bigger scale than in England. Water pollution research was linked on to health of the State in America and the Federal and State Health Services were made responsible for it. But, in England, it was left to the encouragement of small municipal and county bodies and to the Council of Scientific and Industrial Research. Industrial research thinks in terms of benefits to industry and the public health viewpoints are therefore of secondary importance to them. More recently, however, there has been a tendency in England too to bring these activities under the administrative control of the Ministry of Health.

Water pollution problems in India are somewhat unique. When people congregate in large numbers in places of pilgrimage for purificatory baths, the water in these localities is grossly polluted and the same water is also devoutly swallowed by everyone. Commission of nuisance in public thoroughfares, village roads and tank bunds is common in many parts of rural India and all these filth find access to the neighbouring tanks and streams which are also used as sources of drinking water. With the impetus for industrialization in the New India many new industries will come into existence very soon. The disposal of industrial wastes, which hitherto was not of much consequence, will have, now, to be studied with due consideration to proper utilization of our waterways.

No work has been carried out in India on the foregoing aspects of water pollution. American and English experiences may not be directly applicable to Indian conditions without actual data. How the natural purification process will operate under conditions of high water temperatures, bulkier Indian sewage and industrial wastes, it will be hard to figure out without actual investigation. Basic data on these and allied problems is a necessary prerequisite for any scientific planning for the protection and proper utilization of our water sources. Anticipatory control measures are often necessary in handling water pollution problems and research in this field cannot await other developments. It is time that a nucleus for water pollution

research is set up at the centre and along lines suggested by the Bhore Committee.

I wish to thank Professor K. Subrahmanyam for his valuable criticism in the preparation of this article.

SCRUB TYPHUS (TSUTSUGAMUSHI DISEASE) IN BOMBAY

By S. R. SAVOOR, M.B., B.S., B.M.S.

Officiating Assistant Director, Department of Virus Diseases, Haffkine Institute, Parel, Bombay

and

P. DAS MENON

Technician

(An Enquiry under the Indian Research Fund Association)

In collaboration with

S. M. MERCHANT, M.B., B.S.

(B. J. Wadia Hospital for Children, Parel, Bombay)

THE occurrence of scrub typhus (Syn.: rural typhus, tsutsugamushi disease) in Bombay is of more than ordinary interest. In the literature all the cases hitherto recorded, in areas principally outside India, had been from clearing areas bordering on the jungle, plantations of sugar, of cocoanut and of oil-palm, open grassy terrain, camping sites, on banks of inundated rivers—in general exclusively from rural as opposed to urban areas, where the cases of typhus, when they occur, are OX19 in type. In the present series, the diagnoses were made in the first instance during the course of routine examination of sera from pyrexial cases for evidence of typhus infection. A review of the clinical course of the disease confirmed the serological diagnosis. The presence of the dermal lesion—the eschar—characteristic of tsutsugamushi disease, noted in two out of the five cases, and the isolation of one strain in the mouse and demonstration of *Rickettsia tsutsugamushi*, and cross-immunity tests with known strains, proved beyond all possible doubt the nature of infection.

The criterion of a positive serological diagnosis was a minimum agglutinating titre of 1/250 against a suspension of OXK killed by alcohol. Eight cases were found in six months between June to December 1945. Three of the eight were residents of the Bombay suburbs; the rest had been permanent residents of Bombay, who had, for a period of not less than four weeks, never been outside city limits. Short notes on four of the latter five, whose case records were available, are given below:—

Case 1.—A boy, aged 9 years, was admitted to the B. J. Wadia Hospital for Children for continuous fever of five days' duration. The parents gave a history of a pimple on the right axillary fold, four days before the onset of fever. A painful glandular enlargement in the axilla was noted two days after the appearance of the 'pimple' but two days before the onset of pyrexia. On admission, this pimple, which had

SCRUB TYPHUS (TSUTSUGAMUSHI DISEASE)
IN BOMBAY : S. R. SAVOOR, P. DÁS MENON
& S. M. MERCHANT. (P. H. S.) PAGE 753

Photograph of the ulcer on the left axillary fold,
case 3. The hyperæmic areola surrounding the
ulcer can be easily seen.

ulcerated meanwhile, had all but healed. The tonsils were enlarged and the pharynx congested; there was injection of the conjunctival vessels. The tongue was clear; liver (+) and spleen (++) enlarged. The respiratory and nervous systems were normal. The fever was of the remittent type, ranging between 100°F. and 102°F. On the 17th day, the fever touched normal and became intermittent, ranging between 98.4°F. and 101°F., and finally settled down on the 23rd day.

A maculo-papular rash was noted on the trunk on the 9th day of fever and lasted for one day only.

The leucocyte count of 11,200 on the 8th day fell to 6,100 on the 14th day. The differential count did not show any abnormality. Urine showed a trace of albumin.

The Widal reaction being thrice negative, the blood was submitted for the Weil-Felix reaction. The titre for *Proteus* OXK was 1/2,500 on the 14th day, which later rose to 1/5,000. Treatment was symptomatic.

Animal inoculations.—Four mice were inoculated intraperitoneally with a ground suspension of the blood clot which was thrice washed in saline. Infection resulted in two of them, which were therefore killed on the 19th and 21st day of inoculation. Post mortem revealed (i) approximately 1 c.c. of peritoneal exudate, thick and ropy in character; (ii) an enlarged spleen about five times the normal size; (iii) greyish-white exudate on the surface of the spleen. Smears prepared from the scrapings of the peritoneal surface, stained by the Leishman-Giemsa method, revealed intracellular organisms.

Stained by the Giemsa's method the organisms appeared as short rod-shaped bipolar-staining bacilli. With optimum differentiation they were seen to consist of two polar granules that stained purple and were connected by a pale blue rod. Their most characteristic grouping was that of one or more clusters that lay in greatest concentration close to the nucleus; but occasionally they lay scattered beyond the ruptured cell margin, as though prolific multiplication within the cytoplasm had caused rupture of the cell. Average limits of dimensions may be stated as 0.8 to 2.0 μ in length and 0.3 to 0.5 μ in width. Some variation in length and width was seen, but essential structure was constant. They appeared to be identical with the *Rickettsia orientalis* (*R. tsutsugamushi*) described by Nagayo *et al.* (1931) and Lewthwaite and Savor (1936a) and regarded by them as the causal organism of the tsutsugamushi disease (scrub typhus).

Laboratory investigations of this 'Naigaum' strain.

Six rabbits were inoculated intraocularly with 0.1 c.c. of a 1/10 dilution of the peritoneal exudate. Iridocyclitis resulted in the inoculated eye of each rabbit, the evolution of signs did not

differ from those observed with Malayan strains of tsutsugamushi similarly inoculated. Six weeks later, these rabbits were re-inoculated (in the unused eye), two with the 'Ceylon' strain and two with the 'Imphal 8' strains of scrub typhus. The rabbits did not react. Conversely, rabbits convalescent after infection with the 'Ceylon' and 'Imphal 8' strains were immune to the 'Naigaum' strain. Thus the 'Naigaum' strain was immunologically identical with the 'Imphal 8' and 'Ceylon' strains.

Case 2.—A girl, aged 8 years, was admitted into the B. J. Hospital for Children for continuous fever and cough alleged to have been of 15 days' duration. On admission, the conjunctival vessels were seen to be injected. The tonsils were enlarged and there was a slight bronchial catarrh. The alimentary, the nervous and cardiovascular systems were normal. The leucocyte count was normal. There was no enlargement of spleen. Fever was of the intermittent type, ranging between 98.4°F. and 104°F. It came down by lysis on the 25th day. There was neither rash nor complications. None of the glands was enlarged. The Weil-Felix reaction was 1/1,250 OXK on the 18th day and 1/2,500 on the 21st day. Treatment was symptomatic. Animal inoculations were carried out as in the first case, but of necessity as late as the 19th day; a strain was not isolated.

Case 3.—A male, aged 28 years, a cook by profession, was admitted to the G. T. Hospital for headache and continuous fever of seven days' duration. He complained of pain on the left side of the chest and sleeplessness. He gave a history of a 'pimple' on the left anterior axillary fold and painful glandular enlargement four days before he developed the temperature. On admission, a punched-out ulcer was seen, about 3 mm. in diameter, surrounded by a red areola 1 cm. wide (see figure, plate XXXI).

The glands in the left axilla were enlarged, discrete and tender. There was an impaired note on the left base, with poor air entry and fine crepitations. Liver and spleen were not enlarged. The nervous and cardiovascular systems were normal. There was no rash. Fever was remittent in type and lasted for 12 days. There was a secondary rise for two days. Convalescence was rapid.

The ulcer persisted till late in convalescence. The enlargement and tenderness of the lymph glands disappeared with pyrexia. The Weil-Felix reaction was 1/5,000 OXK on the 11th day of fever. Isolation of a strain was not attempted.

Case 4.—A boy, aged 15 years, was admitted to the G. T. Hospital for fever and cough of three days' duration. The patient was dull and appeared to be slightly deaf. The conjunctival vessels were injected. The tongue was dry. Respiratory, cardiovascular and nervous systems were normal. There was marked leucopenia.

The fever was of the remittent type and came down with lysis. The deafness was persistent till convalescence, which was protracted. The Weil-Felix reaction was 1/500 OXK on the 10th day, which rose to 1/1,250 on the 14th day. There was no rash and no ulcer. Attempted isolation of a strain on the 11th day did not succeed.

Commentary

The object of this paper is not so much to give the full clinical account of the four cases of scrub typhus as to prove that cases of scrub typhus can occur within the limits of a metropolitan area. The significance of this observation will be appreciated from the epidemiological remarks given below. Accordingly, only brief case histories are given, and much stress is laid on the isolation of a strain of scrub typhus and its immunological relation to two known strains of scrub typhus.

The studies of Lewthwaite and Savor (1936a, 1936b and 1940) and Lewthwaite *et al.* (1936) on the serology, immunology and epidemiology of scrub typhus and tsutsugamushi disease, once thought to be of separate entities, had shown that though the latter, unlike the former, shows presence of an eschar, the two diseases are identical. Clinical and epidemiological work since carried out by others have confirmed their observations. Two of the four cases (cases 1 and 3) showed an eschar.

Other diagnostic features are pyrexia, rash, lymphadenitis and the Weil-Felix reaction. The rash is not always a constant feature. The lymphadenitis is generalized in scrub typhus in approximately 80 per cent of cases. Such of the cases of scrub typhus which have a dermal lesion, show, in addition, a localized lymphadenitis, often tender, distal to the ulcer. Two of the four cases had lymphadenitis.

In regard to the Weil-Felix reaction, Robinson (1942) had reported that sera from approximately 98 per cent of cases of relapsing fever agglutinated *Proteus* OXK. Savor and Lewthwaite (1941) had shown that in the rabbit, experimental rat-bite fever also gave rise to a Weil-Felix reaction with *Proteus* OXK in high titres. In a personal communication to one of us (S. R. S.), Das Gupta reported that he had obtained this finding in rat-bite fever in man. However, the clinical course of relapsing fever or of rat-bite fever in man is different from that of scrub typhus.

Attempts were made to isolate strains from three out of the four cases; one strain was isolated. Intraperitoneal inoculation of this strain killed the mouse. The post-mortem findings were like those seen in the experimental scrub typhus in the mouse. *R. tsutsugamushi* were demonstrated in the endothelial cells of the peritoneum. Intraocular inoculation of the strain in the rabbit produced an iridocyclitis.

R. tsutsugamushi were demonstrated in the endothelial cells lining the Descemet's membrane. Tests carried out in the rabbit showed a reciprocal cross-immunity with the 'Ceylon' and 'Imphal 8' strains.

All the four patients were residents of Bombay. They came from different parts of the city. Two came from Naigaum, one from Colaba, and the fourth from the Nullbazaar area. They gave a categorical assurance that for a period of one month, prior to the onset of illness, they had never been outside the city limits.

Remarks on epidemiology

How may the known epidemiological data be consistent with the occurrence in a metropolitan area of scrub typhus which has hitherto been considered a disease exclusively of the countryside?

Epidemiological and field observations carried out in Japan, Malaya and Indonesia where the disease had been studied over a period of many years have revealed the following data: (i) The virus of tsutsugamushi had been recovered from many wild rodents: *Microtus monotebelli* in Japan, *Rattus rattus diardii* and *jalorensis* in Malaya and Sumatra. (ii) Certain jungle crows, such as *Centropus javanicus*, known to harbour *Trombicula deliensis*, have been incriminated in the spread of the disease. (iii) The larval forms of a few species of *Trombicula* are the vectors concerned in the transmission of the disease.

The rodent is presumably the reservoir, but its principal rôle may be no more than spreading scrub typhus from an endemic to a non-endemic area. Rats being of migratory habits and liable to transportation from place to place along with food and other commodities, an infected animal may be seen in an area where the disease is not endemic. But in the absence of the vector an infected reservoir is of little danger to man.

Can mites partially fed on an infected animal attack man? In their attempts to transmit scrub typhus by means of bites of larval mites found feeding on wild rats, Lewthwaite and Savor observed that when partially fed mites were interrupted in their feed by gentle mechanical detachment, they refused to 'take' on other animals. In a personal communication Mehta informed one of us (S. R. S.) that he too likewise failed to obtain re-feeding of partially fed mites. To test whether or not there is a tendency for the larval mite to transfer from one host to another consequent on the death of the animal on which it is feeding on at the moment and which may normally be assumed to occur in nature, Kohls *et al.* (1945) 'placed undisturbed colonies of mites from freshly dead rats on dampened soil in battery jars and mite-free rats of the same species confined in the jars and observed daily for a period of 3 days. In no instance were re-attachments observed'. If the tendency of these larval mites, as in the laboratory experiments, is not to transfer from one natural host to

another, it would appear that fully or partially fed mites are of little danger to man.*

It is the unfed but infected vector that is a source of real danger. The nymph and adult forms of *Trombiculae* are vegetable feeders. In their larval stage they attack animals, birds and men. In so much as the virus of tsutsugamushi passes through the egg to the next generation of mites, its infection or its transmission to animal or man takes place only during the larval stage.

The unfed and infected vector can exist only in areas where the ecological conditions are favourable to the development of mites. It may well be that if there are 'mechanical' means of transportation that keeps the unfed larval mites in a starved condition until it gets a host far from its breeding place, it is possible to get sporadic cases of scrub typhus in areas where the environmental conditions are not favourable to mite breeding.

The danger of scrub-typhus infection is therefore in the countryside, in the open grassy terrain, in rural areas amidst coarse vegetation and shrubbery. The name of flood fever in Japan, scrub typhus in Malaya (Fletcher and Lesslar, 1925) and scrub fever (Smithson, 1910), used synonymously with tsutsugamushi, are appropriate in that they indicate very broadly the source or danger zones of infection. Hitherto cases of scrub typhus have never been reported from cities. So much emphasis has been laid on environmental factors that one never expected the disease to occur in city areas. Only familiarity with the disease such few city physicians would have, would lead to its identification. One of us (S. R. S.), who has been studying this disease for several years, did not expect the disease to occur in Bombay. Hence occurrence of cases of scrub typhus in Bombay are of more than ordinary interest to the epidemiologist. Attempts were therefore made to trace the possible source of the infection in the above cases.

Bombay is like any other modern city. The only open spaces that exist are the public parks and playing fields, gardens to residential houses, and vacant building plots. These, though not numerous, exist throughout the various districts of the city where the patients came from. The parks, playing fields, and private gardens to residential houses are all well looked after. It is unlikely that these areas are favourable for mite breeding. Recent field work done under the auspices of the American Typhus Commission in the New Guinea area by Kohls and others suggest that 'well cleared camp sites offer unfavourable environmental conditions for trombiculid mites, and under such conditions

the chances of such mites surviving until opportunity for attacking man is presented are remote'.

Hence, by a process of elimination it would appear that scattered plots of undeveloped land and vacant building sites are sources favourable to the development of mites. These localized empty spaces are uneared for throughout the year. In the hot season, which extends from March till the middle of June, the land is parched with little vegetation in these areas. But after the monsoon rains there is dense growth of native vegetation and of grass. It is during such periods that any semblance of shrubbery is seen. It may well be that during the monsoon and the three or four months following it, these areas form foci of breeding ground of mites. It is well known that during the dry weather larval mites burrow into the soil and come to the surface after rains. From this it would appear that in Bombay, scrub typhus is of seasonal occurrence, as indeed in our cases, extending from the onset of the monsoon in June till about the end of the year. This point will have to be investigated hereafter.* The rainfall in Malaya throughout the year may well be the cause of the distribution of the incidence of the disease throughout the twelve months (Lewthwaite, 1930).

It may be objected that people seldom wander into empty plots of undeveloped land. Three of the four cases were boys. When the monsoon season ceases, in September, and the south-westerly breeze is favourable, kite-flying is a favourite pastime in Bombay. All the three boys admit to having flown kites, though they do not recall having gone into vacant building plots, etc. It is suggested, however, that attempts to retrieve kites or some similar misadventure tempted these boys into the thick vegetation of building sites and of undeveloped land, and exposed them to the attack of mites.

The fourth patient was a cook. He denied ever having gone for months beyond the entirely urban Colaba district of the city, or into the parks, playing fields, or to the shrub areas referred to above. If we postulate that passive mechanical transportation of unfed larval mites is feasible, is it unlikely that the patient may have got the mites on his body at the time of handling vegetables? It may be of fortuitous occurrence, but the eschar on the left axillary fold of the cook is suggestive. According to Gordon (1940), 'persons who handle vegetables, grain, hay and other products, are most endangered'. The vegetables which are marketed in Bombay are grown in the suburbs and in areas well beyond. The authors have

* However, in a recent personal communication, one of us (S. R. S.) was informed that at the Medical Research Council Scrub Typhus Laboratory at Imphal, Assam, it was observed that mites which were detached arbitrarily after a few hours of commencing to feed did re-attach to another test.

* Since writing the above, D. W. Soman, in charge of the Typhus Enquiry at Bombay, recognized 17 cases of scrub typhus during the months of September, October and November 1946, and isolated 7 strains. 'N-serologically positive sample was obtained in any other period during the year'—D. W. Soman (1946).

seen cases of scrub typhus, other than those reported, residing in Bombay suburbs, viz, Bandra, Santa-Cruz, Kalyan, etc. One of us (S. R. S.) has isolated a strain of tsutsugamushi from a patient coming from the Bandra area, which showed a reciprocal cross-immunity with the 'Naigaum' strain isolated in Bombay.

These four cases of scrub typhus indicate that even a metropolitan area such as Bombay is not free from tsutsugamushi disease. We feel almost certain that it is present in the suburbs of the large cities of India, such as Calcutta, Madras, Lahore, etc. Indeed from Alipore, one of the suburbs of Calcutta, Savor and Major M. T. Parker, R.A.M.C., isolated a strain—the 'Calcutta' strain of scrub typhus. In an agricultural country like India, it is to be feared that the importance of scrub typhus has not been properly appreciated. When the data collected by the military personnel during the course of the troop movements in India, Burma and Ceylon regarding the prevalence of scrub typhus becomes available, more will be known about the extent and distribution of the disease, and the parts it plays in the rural economy of India.

The Superintendents of the G. T. Hospital and the B. J. Wadia Hospital for Children are thanked for permission to report on the cases. The photograph was taken by Messrs. R. D. Nayak and R. S. Sawardekar, artists to the Seth G. S. Medical College, Parel, Bombay.

The Indian Medical Gazette Fifty Years Ago

ELEPHANTIASIS

(Reprinted from the *Indian Medical Gazette*, Vol. 32, December 1897, p. 463)

FIFTEEN years or more have elapsed since Manson first demonstrated the causal relationship between elephantiasis and other forms of filarial disease. Since that period experience has so amply confirmed these observations, that it is somewhat startling to find any revival of scepticism regarding this important matter. The fact that such scepticism does exist makes it worth while to draw attention to the subject, and to recapitulate some of the facts, which seem to prove that elephantiasis arises from causes similar to those which produce lymph-scrotum, lymphangiectasis, chyluria, and other forms of filarial disease.

In the first place, there is the well-known fact that these diseases coincide in their geographical distribution. Extremely interesting in this connection is the following fact:—

In a certain limited area of a large town, cases of elephantiasis of the legs are so numerous that persons suffering from the disease may be seen, almost at any moment of the day, walking in the streets. In the heart of the district there is a hospital in which cases either of elephantiasis or other forms of filarial disease may almost always be seen. It is, however, not only in the same district that we find these diseases co-existing but in the same houses. There is, therefore, some factor in the conditions under which certain persons reside that renders them liable to suffer either from elephantiasis or one of the other forms of filarial disease.

Still more striking is the fact that these diseases are not infrequently found to attack the same individual simultaneously. An interesting case of this nature was recorded by Manson, in which elephantiasis of the leg and lymph-scrotum were found to co-exist in the same patient. Moreover, the periodical attacks of fever, from which the patient suffered, were accompanied by simultaneous pains and swelling of both the legs and the scrotum. This case would seem to furnish in itself sufficient evidence of the identity of the diseases. All surgeons, who are in the way of meeting with cases of elephantiasis, are familiar with the fact that elephantiasis of the scrotum, in its early stages, frequently resembles lymph-scrotum in appearance, and is subject to similar discharges of lymph. It is also not an uncommon experience to find 'lymph-scrotum' occurring in the neighbourhood of the cicatrix left after the removal of elephantiasis of the scrotum; and the latter disease has been known to follow the removal of a lymphangiectasis of the lymph-glands of the groin. A third and most forcible argument in favour of the identity of

The vitamin intake in Febrile conditions

The restricted diet associated with febrile illnesses involves a reduced intake of vitamins and minerals at a time when the heightened metabolic rate calls for an increase.

A multiple vitamin and mineral supplement (Complevite) is an essential addition to all such diets.

Supplying the full physiological requirements in this way offers the greatest likelihood of shortening the illness.

COMPLEVITE

The adult daily dose provides:—Vitamin A 4,000 i.u., vitamin B₁ 200 i.u., vitamin C 400 i.u., vitamin D 300 i.u., calcium 153 mg., iron 68 mg., trace minerals 3 p.p.m.

Further particulars concerning Complevite and Fertilol from Martin & Harris Ltd., Mercantile Building, Lall Bazar, Calcutta.

Products of Vitamins Limited, London, England.

FERTIOL

(VITAMIN E and all the other factors of Wheat Germ Oil)

Used in the treatment of habitual abortion, sterility of dietary origin and certain neuro-muscular degenerations.

Fertilol is a highly active natural and stable source of vitamin E and of the other factors of wheat germ oil. Each 5 minim capsule is standardised to contain 3 mg. α -tocopherol.

Wheat germ oil has given better clinical results¹ in some trials and shown properties additional to those of pure α -tocopherol.

CONTUSION OF THENAR MUSCLES

A treatment by means of Elastoplast

CASE HISTORY

An iron worker, aged 26, fell against an iron bar which he struck between the thumb and first finger. When examined on the 6th August there was clinical tenderness of the thenar muscles but x-ray showed no fracture or dislocation.

A one-inch wide Elastoplast Plaster was applied, spica fixation.

A fortnight later, there was slight tenderness and another Elastoplast Plaster was applied.

Fig. 1

On the 10th September the Elastoplast was removed. There was no tenderness or pain on gripping and the patient was discharged.

The details and illustrations are of an actual case. T. J. Smith & Nephew Ltd., are privileged to publish this instance, typical of many in which their products have been used with success in the belief that such authentic records will be of general interest.

Fig. 2

Elastoplast Plasters available are 1" wide \times 1 yd. ($1\frac{3}{4}$ yds. when stretched) and 1" wide \times 3 yds. ($5\frac{6}{8}$ yds. when stretched). Elastoplast, Elastocrepe, Jelonet and Gypsona are products of T. J. Smith & Nephew Ltd., Hull, England.

TO ALL USERS OF
X-RAY & **ELECTRO-MEDICAL**
EQUIPMENT
Here is an important announcement

SALE & SERVICE OF
WATSON
British Made
X-RAY EQUIPMENT

We are pleased to be able to announce that arrangements have been completed with the **GENERAL ELECTRIC CO., (INDIA), LTD.** for the setting up of an efficient organisation for the sale and servicing of Watson X-ray equipment throughout India and Pakistan.

The organisation—which forms the X-ray and electro-medical department of the G.E.C. (India), Ltd.—will be staffed by practical X-ray engineers with long experience in servicing Watson equipment.

Present-day Watson X-ray equipment is recognised to be amongst the finest in the world. Much of its success is due to the development work carried out in the Research Laboratories of the General Electric Co., Ltd., of England, with whom we are closely associated. Information concerning new X-ray equipment for diagnosis and therapy will gladly be forwarded on request.

G.E.C.

THE GENERAL ELECTRIC CO. (INDIA), LTD.
MAGNET HOUSE, CENTRAL AVENUE, CALCUTTA

these diseases is the fact that both are characterized by periodical attacks of fever of a similar type and accompanied by swelling and pain of the affected area of the body, as well as of the lymphatic glands which drain that area.

The only argument, so far as we are aware, that has ever been brought forward against the identity of these diseases is the fact that filarial embryos are rarely found in the blood of patients suffering from elephantiasis. But filarial embryos are not always found in the blood in cases of undoubted filarial disease, such as chyluria; in fact a large proportion of such cases are distinguished by the absence of any hæmatozoa. The absence of embryos from the blood is an indication either that the parent worms are dead, or that the lymphatic channels which they inhabit are completely shut off from communication with the blood stream—nothing more. The pathological conditions which characterize elephantiasis are such that filarial embryos cannot penetrate to the blood stream.

When elephantiasis is fairly established, the locality inhabited by the filariæ is shut off from the rest of the lymphatic channels, so that even if the parent worms be still alive, their offspring cannot find their way into the blood stream.

Hence embryo filariæ are hardly ever seen in the blood in cases of elephantiasis.

That there are a small number of cases of elephantiasis of the limbs that are not of filarial origin is not disputed. Any lesion, which results in complete stagnation of the lymph circulation in a limb, will produce elephantiasis. Numerous cases of elephantiasis have been recorded as occurring in persons, who had resided the whole of their lives in the British Isles, and Hutchinson draws attention to cases of recurring erysipelas associated with elephantiasis and unconnected with filarial disease.

We cannot do better than conclude with the following quotation from Manson: 'If we do not accept the parasitic theory as explaining tropical elephantiasis, then we are obliged to conclude that in the tropics there are two forms of this disease; that they affect the same parts of the body, are found in the same districts, are characterized by the same sort of fever, inflammation of the lymphatics, and skin lesions: that, in fact, they are in every respect identical, and only differ in their ætiology. I think this is so unlikely that few on reflection will maintain it'.

Current Topics, Etc.

Latent Syphilis. Study of One Hundred and Sixty-nine Cases Observed for Ten Years or More

By J. W. JORDON
and
F. A. DOLCE

(From the *Bulletin of Hygiene*, December 1946, Vol. 21, p. 810)

This study comprises 169 patients observed for ten years or more, of whom 100 were well treated and 69 poorly treated or untreated; the former (group II) received 40 or more injections of an arsphenamine and bismuth, the latter (group I) less than 40. Group I included 19 white men, 11 white women, 19 Negro men and 20 Negro women; they were observed for an average period of 13 to 14 years, the longest period being 29 years; they received an average of 5.8 injections of arsenic and 5.5 of bismuth. During the period of observation, serum reactions showed considerable fluctuations, positive reactions often becoming negative and then positive again without treatment.

Twenty-seven of these 69 patients developed complications, of which cardiovascular lesions were by far the commonest; this figure may be unduly high because of the large proportion of Negroes, but the authors estimate that 20 to 25 per cent of poorly treated latent syphilitics may be expected to develop cardiovascular lesions in later life.

Among the 16 patients with negative serological reactions for 4 years, none had certain and three had probable late complications; of the 24 whose reactions varied, two had certain and one probable complications; of the 29 whose sera were consistently strongly positive, 23 had certain complications. These facts suggest that a persistently positive reaction is a bad prognostic sign, whereas a fluctuating reaction or one which reverses carries a good prognosis; the incidence of late complications was 55.5 per cent in those patients who gave a history of primary or secondary syphilis, whereas it was only 39.2 per cent in the whole group: this suggests that the theory that frank early syphilis protects against late complications is not valid.

Group II included 37 white men, 35 white women, 15 Negro men and 13 Negro women: they were observed for an average of 11.3 years, the longest period being 19 years; they received an average of 28.7 injections of arsenic and 78 of heavy metal.

The reactions of these patients fluctuated considerably. From the serological point of view those who received 20 to 29 arsenical injections progressed most favourably, further injection gave no better results and the amount of heavy metal had no appreciable effect on serological outcome. It is suggested that 20 to 29 injections of arsenic and 40 to 60 of bismuth constitute the optimum total dosage and that arsenic is more effective than heavy metal. Only 4 of the 100

patients in group II developed complications, so that it is clear that adequate treatment reduces the hazard of late effects and improves the prognosis.

It is of interest that one patient in group I who had a negative cerebrospinal fluid developed paresis fourteen years later.

Arsenical Dermatitis Successfully Treated with BAL

(Abstracted from the *British Medical Journal*, 26th July, 1947, Vol. II, p. 132)

In a memorandum published in the *British Medical Journal*, 26th July, 1947, p. 132, J. Lawrence Reeve records the following two cases:—

Case 1.—A labourer, aged 27, first attended the V.D. clinic at the Royal Victoria and West Hants Hospital, Bournemouth, had a large ulcer at the base of the glans penis, and dark-ground examination revealed the presence of *Treponema pallidum*. Treatment was started at once with 300,000 units of penicillin twice daily for five days, together with N.A.B. and bismuth. He was given 0.45 grain of N.A.B. twice weekly for four injections, followed by 0.6 grain twice weekly for a further eight injections—a total of 6.6 grains of arsenic. Bismuth 0.2 grain twice weekly was given for six weeks, total 2.4 grains. An erythematous rash with desquamation appeared on the limbs and trunk on the 11th day of commencement of treatment. The patient was given daily intravenous injections of 6 ml. of calcium thiosulphate for 7 days. There was no improvement; he then had oedema of the hands, fissuring of the palms with some exfoliation, and similar fissures at the ankles and on the soles of the feet. There was oozing from all fissures. Then treatment with 2 ml. of BAL (British anti-lewisite) intramuscularly every four hours was started. The next three days he had 2 ml. twice a day and then 2 ml. a day for two days. In less than a month the hands and feet were quite healed and the patient was back at work.

Case 2.—A housewife, aged 26, first attended the V.D. clinic on 18th September, 1946, with a secondary syphilitic rash involving the arms and trunk (Wassermann ++, Kahn +++). There was some dental sepsis, but as she was seven months' pregnant it was thought advisable to prescribe arsenic and bismuth as well as penicillin. She was given 600,000 units of penicillin daily from 25th September to 1st October; three injections of 0.45 grain and five of 0.6 grain of N.A.B. (a total of 4.35 grains of arsenic) and eight injections of 0.2 grain of bismuth between 25th September and 23rd October. On 30th October, erythematous patches with oedema were noticed on the buttocks, and smaller patches were seen at the bends of the elbows. Calcium thiosulphate, 6 ml., was prescribed twice weekly till 15th November. As there was no improvement, BAL was given from 22nd November to

25th November. Owing to her confinement the patient did not attend again until 22nd January, 1947, when no rash was to be seen, and she stated that it had quite disappeared before her confinement on 17th December.

It seems to the writer that BAL may well be the answer to the syphilologist's prayer, for, instead of cases of arsenical dermatitis being in hospital for weeks at a time, they may now be treated as out-patients. The response is most dramatic, as the rash begins to clear as soon as treatment is started.

The Berger-Kahn Test for Syphilis

By J. H. FODDEN

and

E. J. MADDUX

(Abstracted from the *British Medical Journal*, 26th July, 1947, Vol. II, p. 131)

It was found that certain dyes when mixed with a suitable alcoholic heart extract caused, in syphilitic sera, not only the formation of coloured precipitates but also an increase in the sensitivity of the reaction which was directly proportional to the amount of dye present in the antigen. Janus green and Victoria blue were the dyes of choice, as they appeared to be the best sensitizers and in their presence heavy flocculation rapidly occurred. Sera containing amounts of syphilis antibody too small to react with a given antigen without dye showed marked flocculation in the presence of Victoria blue or Janus green. Victoria blue is better, as very fine dispersion of the alcoholic antigen could be obtained with this dye as compared with Janus green.

For the purpose of the investigation the writers carried out in triplicate 970 routine serological test for syphilis.

The standard antigen for the Kahn test as supplied by the Ministry of Health Special Laboratories was used.

A stock antigen (which keeps for at least a year at room temperature) is prepared thus: To 10 parts of standard antigen containing 0.6 per cent of cholesterol and having a titre of 1 + 1.2 add 1 part of tinct. benz. co. B.P. To 10 ml. of this mixture add 17 mg. of Victoria blue 4R (Gurr). The container should be kept well stoppered.

Method of Test

(1) Pipette 1 part of the stock antigen (0.1 ml.) into the bottom of a dry tube. (2) Add 10 parts (1 ml.) of 0.85 per cent sodium chloride solution rapidly to the tube from the pipette. This dispersed antigen is sufficient for at least thirty tests, and can be used at once or during any time on the day of preparation. It should be shaken immediately before use. (3) Place on a prepared glass slide one drop of the serum to be tested and add a drop of equal size

of the dispersed antigen. (4) Mix the drops with a glass rod, rock the slides for two minutes, and read results immediately. (5) The results are read macroscopically, and as a distinct aid to easy reading the slide is held over a sheet of white paper. Positive reactions show large deep blue floccules easily visible in a water-clear fluid. Negatives at two minutes show no flocculation whatever, the mixed drop remaining quite homogeneous and of a sky-blue colour.

The standard Kahn method often showed lower numerical grading, and in the case of weak positives by the other methods some were missed. This was particularly marked when dealing with old treated cases. Difficulty in reading weakly positive standard Kahn tests is overcome in the Berger-Kahn test by the pronounced staining of the floccules which occurs. The strongly positive sera are easily read, as the floccules in this case are very large and absorb the whole of the dye. In the writers' experience, whenever this result was obtained they always noticed that the Wassermann reaction read 2 + or 3 +. The writers wish to emphasize that every one of their positive Wassermann results gave a positive reaction with the Berger-Kahn test.

Comment

The reaction should be read at two minutes, and not four minutes as recommended by Berger, as reading at the latter time yields a high proportion of mixtures showing very faint granularity, which can lead to some confusion.

Berger made no reference to the gradation in size of the blue floccules in assessing the strength of a positive result. It is quite easy to grade positives on the size of particles given by the Berger-Kahn test. We found such gradation in particle size very constant and most helpful.

A. B. R. C.

The Rapid Treatment of Syphilis

(Abstracted from the *Medical Journal of Australia*, 28th June, 1947, Vol. I, p. 791)

A NEW report now comes from the New Mexico Intensive Treatment Centre, where all stages of syphilis except late syphilis of the central nervous system were treated. Five different schedules of rapid treatment have been used over a period of two years. The schemes of treatment employed were as follows: (a) The 'modified Schoch régime', in which a daily injection of 'Mapharsen' was given on six days a week for twenty doses, together with a weekly injection of 200 milligrammes of bismuth subsalicylate. The dose of 'Mapharsen' was 0.6 gramme for adults weighing more than 120 pounds, smaller patients receiving proportionately less. (b) The 'multiple injections—25-day schedule', in which daily injections of

'Mapharsen' were given (on six days a week) for a total of twenty-two injections, the dosage being the same as in the previous method. A dose of 200 milligrammes of bismuth subsalicylate was given on the first day of treatment and repeated with every fifth 'Mapharsen' injection. (c) The administration of penicillin alone by sixty injections of 40,000 units each every three hours, a total of 2,400,000 units in seven and a half days; no follow-up treatments were given. (d) The '8-6-3 schedule'. During an eight-day period eight daily injections of 'Mapharsen' were given, the dosage being as in the previous methods, with three injections of bismuth subsalicylate (on the first, fifth and eighth days), and penicillin in doses of 10,000 units every three hours for sixty injections. (e) The '5-12-3 schedule', during a nine-day period, five injections of 'Mapharsen' were given (on the first, third, fifth, seventh and ninth days), with three injections of bismuth subsalicylate, each of 200 milligrammes (on the first, fifth and ninth days), and seventy-two injections each of 16,667 units of penicillin every three hours to a total of 1,200,000 units. Serious reactions to these schemes of treatment were few. Five cases of arsenical dermatitis occurred, two of which followed the 'multiple injections—25-day schedule' and one each from the other three methods which included arsenic therapy. All patients responded well to local treatment and the use of BAL. One instance of agranulocytosis occurred in a patient receiving the 'multiple injections—25-day treatment'. The most serious reactions were in patients who developed encephalopathy while being treated by the '8-6-3' régime; these patients nearly died, but recovered with no sequelæ after the use of supportive therapy, sedation and BAL.

All five methods were considered effective in rendering patients non-infective in a short time. Under hospital conditions they are regarded as safe for use by medical personnel trained briefly in the relevant techniques and indications, except for the '8-6-3 schedule'. The technique showing the best results by serological standards was the '8-6-3' régime; by the use of this method, 80 per cent of all patients suffering from secondary syphilis were treated with satisfactory results. The '8-6-3' régime is, however, not considered safe, and the '5-12-3' technique, the use of which has not been followed by the same toxic manifestations, is thought to be the most promising method. The least satisfactory results were obtained with the 'modified Schoch' method. The penicillin régime is undoubtedly the safest, but the percentage of unsatisfactory results from its use in these investigations was disappointingly high. For the present, however, arsenic seems indispensable, at least for certain phases of the infection. The most effective attack on syphilis appears to require the combined forces of arsenic, penicillin and bismuth.

A. B. R. C.

Studies of Maternal and Infantile Blood Factor Relationships

By LUCY M. BRYCE
RACHEL JAKOBOWICZ

and

NORMA McARTHUR

(Abstracted from the *Medical Journal of Australia*, Vol. II, No. 7, 17th August, 1946)

ALL blood samples were tested for the Rh factor with a potent standard (anti-Rh₀) serum of appropriate group or absorbed with cells or saliva on glass slides. Samples not agglutinated by this standard serum were retested with an anti-Rh₁ (anti-Rh₀') serum. It is recognized that a few patients classified as Rh-negative by this method may have belonged to subgroup Rh" as no anti-Rh" serum was available at the time when these studies were made.

The total number of women examined at the first visit to the antenatal clinic was 2,230.

The iso-agglutinin titres obtained in pregnant women ranged from 4 to 4,000 with a mean of 107.08 ± 4.68 for anti-A and 46.28 ± 1.52 for anti-B.

Out of 2,230 women the group of 850 mothers and babies may be divided into four sections: (i) Those in whom the major blood group factors (A, B, O) and Rh factors are either the same or compatible. Compatibility comprises a combination of a mother of blood group A, B or AB with a child of blood group O, and an Rh-positive mother with an Rh-negative child. It may be noted that the combination which potentially could stimulate Hr antibodies in the maternal serum is not possible with an Rh-negative child. (ii) Those with incompatible A and B factors, but compatible Rh status. (iii) Those with the same or compatible A and B factors, but incompatible Rh status. (iv) Those with potential incompatibility of both A and B factors and Rh status.

These four sections have been analysed with a view to detecting whether there is a significant difference between them in respect of possible damage to the foetus or the infant. This possible damage has been considered under the headings of stillbirth, premature birth, *icterus gravis*, jaundice of lesser degree, and anaemia. With regard to anaemia, for the purpose of this analysis, we included only cases in which anaemia was detected during the first few post-natal weeks in babies who did not earlier display any of the other manifestations considered possibly attributable to heterospecific pregnancy.

It is noteworthy that in the third and fourth sections, together include all cases of Rh incompatibility, the incidence (28.6 per cent) of abnormalities in the baby is almost double that of the incidence (14.5 per cent) in the first and second sections, in which the Rh status of the mother and that of the child are compatible. The difference is statistically significant. On the other hand, if the first and second sections are compared with each other, the percentage of abnormalities in the first section in which A, B, O factors are compatible is approximately 14 per cent, and in the second section, in which the A, B, O factors are incompatible, it is 17 per cent. This difference is not statistically significant, nor is there any significant difference between the third and fourth sections, in which, however, the numbers may be too small for valid comparison. It is to be noted, however, that while the highest incidence of definite *icterus gravis* occurs in the groups in which Rh status incompatibility exists, the incidence of anaemia is highest in the group in which A, B, O incompatibility is present. While the number of cases of anaemia is not large enough for effective comparison, it is considered possible that this condition either occurring alone or preceded earlier by relatively mild jaundice, may be a more frequent result of A, B, O incompatibility than are the more dramatic and fulminating forms of haemolytic disease, which can usually be correlated with Rh incompatibility.

There are, in the present series, four cases of *icterus gravis* in which Rh incompatibility could not be detected, but in which an A, B, O incompatibility was present. In all of these four cases of *icterus gravis*, and in all cases of anaemia so far detected in this series, the mother's serum titre for the incompatible A and/or B factor was appreciably higher at or after delivery than it had been at the first test during pregnancy; but it must be noted, on the other hand, that there are many cases in which a rise in titre, particularly after delivery, has no apparent deleterious effect on the foetus or infant.

The incidence of 10 cases of *icterus gravis* in 850—that is approximately 1 in 85—is higher than is usually estimated.

In agreement with other workers the writers have found that the titre of Rh-antibodies in the maternal serum bears no relation to the severity of the disease in the child, nor in every case to the number of previous opportunities for stimulation.

All the nine cases of anaemia occurring as the only manifestation of haemolytic disease were found in first, second or third babies, and seven of them were found to be associated with A, B, O incompatibility.

Theoretically, maternal immunization could be brought about by the escape of foetal red cells or by the diffusion of specific soluble substances from the foetal to the maternal circulation.

An investigation, so far comprising 111 cases, has been made of the relationship between fluctuation of iso-agglutinin titre in the maternal serum during pregnancy and foetal incompatibility. In 45 of these 111 cases, mother and child were of compatible blood groups, and in none of these was a rise in agglutinin titre demonstrable eight to ten days after delivery. Eight of these 45 children were tested and seven were found to be secretors. In the remaining 66 cases of this series the child's blood group was incompatible with that of its mother. Of these 66 cases, in 35 a rise occurred in maternal agglutinin titre and in one a fall in blood taken eight to ten days after delivery. Twenty-eight of the children whose mother's serum titre had risen or fallen were found to be secretors. The remaining eight children were not tested. No alteration was detected in the maternal serum titre in 30 of the 66 cases in which incompatibility was present. Fourteen of the children in this group were found to be non-secretors and nine to be secretors, and seven were not tested. It is possible that if more frequent testing of the maternal serum had been practicable a rise in titre would have been detected in more of these cases in which the child was a secretor. Even as they stand, however, the figures suggest a relationship between the secretor state of the child and rise in the corresponding maternal agglutinating titre. They therefore support the contention that iso-immunization is usually brought about by passage of water-soluble group-specific substances across the placenta.

The data elicited from the interviews with 100 each of Rh-positive and Rh-negative women are given in table VIII and illustrated in figure 2. Miscarriages, abortions and stillbirths are all included in this table under the heading of foetal deaths. Among these women it will be seen that the difference between the number of foetal deaths occurring in the Rh-positive and Rh-negative groups.

Analysis of data concerning 1,379 parous women obtained from the recorded histories also shows that while the total incidence of abortions, stillbirths and prematurity (collectively termed accidents) is of a similar order among Rh-positive and Rh-negative women, there is a significantly greater proportion of such accidents in the first pregnancy among both Rh-positive and Rh-negative women than in the second and third. It is interesting to note that in this series there were three Rh-negative women who each had had seven pregnancies all resulting in living children, one who had had eight (all children living), one who had had nine (eight living children), and one who had had fifteen pregnancies and fifteen living children.

The potential danger of accidents of pregnancy arises most frequently in the cases in which Rh-negative women have Rh-positive foetuses. This is inevitable if the mating has been with a homozygous Rh-positive male—that is, in about 38 per cent of all matings. Fifteen per cent of matings will be with Rh-negative men and the remaining 47 per cent with heterozygous Rh-positive men. The latter matings will give even chances of the child's being Rh-positive or Rh-negative. However, the liability to such accidents is much less than these figures would suggest, as approximately only 1 in 50 of all Rh-negative women are readily sensitized by an Rh-positive foetus.

On Complete Removal of the Prostate. A Preliminary Communication

By H. S. SOUTTAR, C.B.E., M.Ch., F.R.C.S.

(Reproduced from the *B.M.J.*, 28th June, 1947, p. 917)

It will be generally agreed that the extravasical approach to the prostate introduced by Millan presents considerable advantages over the older transvesical methods. It enables one to observe every step of the operation in a way which was formerly impossible, bleeding is readily controlled, and the post-operative period is short and easy. Some recent experiences have, however, suggested to me that the operation for prostatic obstruction performed by this route is still capable of substantial development, and although some considerable time must elapse before this can be established it seemed worth while to place these experiences on record.

HISTORY OF A CASE

In operating a short time ago upon a man of 75 with obstruction of some standing I was surprised to find that instead of enucleating an adenoma as I intended I was enucleating the entire prostate, which had become detached from the triangular ligament. Moreover, on drawing the prostate away from the triangular ligament a tube of urethra emerged from that structure as a substantial muscular cylinder four centimetres in length. The only course was to divide this tube close to the prostate, which was then easily excised from the neck of the bladder after division of the ejaculatory ducts. The urethra was sutured to the neck of the bladder, and the latter was then sutured firmly to the triangular ligament, completely obliterating the prostatic cavity. To my great relief the operation was a complete success, the patient, a rather feeble old man, passing water normally on the sixth day.

ANATOMY OF THE PROSTATE

On discussing the case with Prof. Wood Jones he told me that the free urethral tube is a fact of normal anatomy, although it was quite new to me, and I know of no reference to it in any textbook. What was abnormal in my patient was the ease with which the prostate became detached. I have since carried out a

Fig. 1.—Normal anatomy.

Fig. 2.—Ligaments divided; prostate retracted.

number of dissections which fully confirm this view. The normal anatomy is as follows:

The prostate is attached to the back of the pubes by two dense bands of great strength—the pubo-prostatic ligaments. Each of these forms a rounded

tendon three or four millimetres in diameter, separated by a deep recess, the cave of Retzius, into which emerges the dorsal vein of the penis. On dividing these ligaments the prostate is easily shelled out from its bed,

Fig. 3.—Urethra divided; prostate excised.

Fig. 4.—Urethra sutured to bladder.

which is formed in front by the levator prostatae muscles and further back by the dense fascia of Dénonvilliers, which separates the prostate from the rectum. As the prostate is drawn upwards the membranous urethra emerges from the compressor muscles of the triangular ligament as a muscular tube three to four centimetres in length. It is true that a venous plexus is opened up, as this surrounds the prostate, but it does not appear to be of great moment and bleeding from it is easily controlled.

Fig. 5.—Bladder sutured to urogenital diaphragm.

The existence of this urethral tube is obviously of great importance, for it enables us to provide a complete epithelial lining after removal of the prostatic urethra, and would seem to avoid any risk of stricture. It is of course a fragile tube and requires careful handling, but it is substantial enough to allow of accurate suture into the neck of the bladder. It is convenient to proceed as follows:

OPERATIVE PROCEDURE

A No. 12 rubber bougie is passed into the urethra as far as the prostate or into the bladder. The prostate is exposed by a suprapubic incision and drawn upwards so that the pubo-prostatic ligaments are clearly seen. These ligaments are now divided, the bougie providing a guide to protect the urethra, when on drawing the

Fig. 6.—Normal anatomy.

prostate upwards the urethra will emerge from the triangular ligament carrying the bougie. The prostate can now be shelled out from its bed without difficulty; the bougie is withdrawn from it, but remains in the urethra, which is divided at the apex of the prostate. The prostate is turned forward and detached from the bladder after dividing the ejaculatory ducts. The bougie supporting the urethra is passed into the bladder and cut through a puncture in its wall. The urethra

is sutured with fine catgut to the neck of the bladder, which is now securely sutured to the triangular liga-

Fig. 7.—Ligaments divided; prostate retracted.

ment, obliterating the prostatic cavity. The bougie is withdrawn through the bladder so far that it remains as a support for the new junction between the bladder and the urethra. The bladder is drained by a suitable suprapubic tube, into which the end of the bougie may conveniently be fixed. The bougie may be removed in four days and the suprapubic tube as soon as it is certain that the patient can pass water.

COMMENT

The operation described is of course only a development of the brilliant operation devised by Millan, but it may be a development with considerable possibilities. If further experience confirms its practicability it would seem to present certain definite advantages. The prostate is removed as a whole and the technique of its removal is little affected by its precise pathology. Indeed, it might well be applicable to early carcinoma. The cavity left is completely obliterated and later hæmorrhage is unlikely. A complete urethra is provided from the outset and the risk of a stricture is minimized. So far the operation has been carried out in only a few cases, and obviously a wide experience will be required before its value can be assessed. But it would seem to be based on sound anatomical principles, and sufficient success has already been achieved to convince me that it is worthy of an extended trial.

Effect of Oxygen on Malaria (An *in vivo* Study in Ducks)

By R. H. RIGDON

and

NONA B. VARNADOE

(Abstracted from the *Journal of Laboratory and Clinical Medicine*, Vol. 32, No. 1, 1947, p. 57)

A study had been made to determine the effect of increasing the amount of oxygen available to ducks to see the effect upon the course of malaria infections and the results reported.

The authors placed normal ducks and ducks with a severe malarial infection in an oxygen chamber. Control experiments at the atmospheric pressure were also done.

The peak of parasitæmia was reached on the fifth day but the parasitæmia was much higher in those kept in the oxygen chamber than it was in the control group. A progressive decrease occurred in the number of red cells and in the hæmatocrit readings in all ducks regardless of whether they were in the control group or in the oxygen chamber. The red blood cell counts and the hæmatocrit readings of non-malarial birds kept in the oxygen chamber with the infected birds decreased during the first four days following which time they rapidly increased to within the range of normal. Normal ducks used for the controls did not show any significant variation in the red cell count

and hæmatocrit reading during a corresponding interval.

Ducks with a high degree of parasitæmia survived for a much longer time (10 to 18 hours longer) when put into a chamber with a high concentration of oxygen than similarly infected ducks kept at normal atmospheric pressure.

The increased amount of oxygen apparently helps to compensate for the decrease in the amount of hæmoglobin which is present in the highly infected birds. The anæmia results from the rapid destruction of red cells by the plasmodia. The important factor in all types of acute malaria seems to be the rapidity in which the anæmia may develop. The fact that ducks with a severe malarial infection showed immediate improvement, either following a transfusion with duck red cells shown elsewhere or when they are put in the presence of an increased concentration of oxygen in these experiments, would suggest that clinical subjects with acute malaria and symptoms of shock should be given a transfusion and placed in an oxygen chamber at the same time that a plasmodial drug is given.

Experimental and clinical studies elsewhere indicated that shock may occur in severe malarial infections. In the treatment of shock from any cause, all efforts should be directed to improve the circulation of blood through the tissue so that oxygen can be delivered at a higher partial pressure. A 100 per cent concentration of oxygen had been administered to patients for forty-eight hours without any evidence of pulmonary irritation.

There is however nothing in the experimental studies to indicate that oxygen *per se* will cure malaria.

As far as it is known there are no contradictions to the use of transfusions and oxygen in the treatment of a patient with malaria.

Lobectomy Brings Low Mortality

(From the *Journal of the American Medical Association*, Vol. 133, 26th April, 1947, p. 1284)

ALTHOUGH the operation of lobectomy has been performed for many years, its value and the low operative mortality of the procedure may not be fully appreciated. Recently, Meade and his colleagues discussed results of 236 lobectomies performed at the Kennedy General Hospital between November 1943 and May 1946. Lobectomy was performed for bronchiectasis, pulmonary cyst, chronic suppuration, bronchial adenoma, adenomatosis, tuberculosis, neurogenic sarcoma and actinomycosis. Bronchiectasis was by far the most common indication. Only one patient died. This report offers a splendid illustration of the effectiveness and especially of the safety of lobectomy as performed to-day.

Hunger CEdema

By F. A. DENZ

(Abstracted from the *Quarterly Journal of Medicine*, Vol. 16, January 1947, p. 1)

1. TOTAL plasma-proteins are decreased in cEdema cases. Mean values of 5.24 gm. per 100 c.c. of plasma in slight cases, 5.07 in moderate cases, and 4.90 in severe cases were obtained as compared with 7.04 gm. per 100 c.c. for a normal control group. Plasma-albumen values in 14 cEdema cases ranged from 2.58 to 3.81 gm. per 100 c.c. of plasma. The lowered plasma-proteins are believed to result in the accumulation of cEdema that commences with the first lowering of the protein level. The view that there is a critical level of plasma-protein for the production of cEdema is not accepted.

2. Plasma-volumes determined by the Evans blue method give values from 1.74 to 3.30 litres per sq.

metre of body surface. High values were obtained while oedema was present, and where the examination was repeated after loss of oedema the plasma-volume fell to normal. This fall in plasma-volume was associated with hæmoconcentration as shown by a rise in hæmoglobin and plasma-protein. This was taken to indicate that hydræmia occurs in hunger oedema.

3. Four cases of apparently cured oedema were exercised with reappearance of the oedema. Two cases with oedema were exercised while on full diet with persistence of the oedema until the patients were allowed complete rest. Exercise appears to be a potent factor in the production and retention of oedema.

4. Daily plasma-protein determinations on oedema cases showed a diurnal variation which was probably due to variation in the degree of hydration of the blood.

5. The inaccuracy of the clinical assessment of oedema is illustrated by a patient showing minimal oedema who lost 8½ litres of oedema fluid. This case is contrasted with another showing severe oedema, but losing only 2 litres of oedema fluid. It is shown that much excess fluid may be hidden in the deeper connective tissues of the mediastinum and abdomen.

6. The extracellular fluid volumes have been determined by the thiocyanate method and in non-oedematous cases ranged from 20 to 28 per cent of body weight. Extracellular fluid volume is shown to decrease in loss of oedema.

7. Urinary chloride excretion was high during loss of oedema. While as much as 28 gm. of chloride were being lost per diem, the kidney excreted a urine of chloride concentration greater than that of the plasma, with resultant fall of plasma-chloride concentration. During periods of exercise while oedema fluid is collecting, the urinary chloride concentration is less than that of the plasma, indicating chloride retention. These changes are believed to be the result of the tubular activity.

Medicolegal

ABNORMALLY LONG PREGNANCY RAISES NO PRESUMPTION OF INFIDELITY

(Abstracted from the *Journal of the American Medical Association*, Vol. 133, 1st February, 1947, p. 347)

THE husband filed suit for divorce on the ground of adultery, the case being heard in the Supreme Court, special term, Queen's County, New York.

The partners were married on 12th March, 1944. On 24th April, 1944, the plaintiff, an officer of the merchant marine, left the country for duty in the Pacific, returning to the United States, 4th January, 1945. On 14th April, 1945, the defendant gave birth to a child which she claims is the child of the plaintiff. The plaintiff offered no evidence of any misconduct on the defendant's part but asked for a decree solely on the hypothesis that it is impossible for a period of 355 days to elapse between coition and parturition.

A gynaecologist who taught at the Yale Medical School, called as an expert witness by the plaintiff, testified that the accepted period of gestation is 270 days, with the longest authenticated period being 320 days. He admitted that there was a non-authenticated case of 369 days. A physician called by the defendant as an expert testified that the ordinary period of gestation is 280 days, or ten lunar months, but there are instances of 328 days and 344 days.

The physician who attended the defendant during her pregnancy testified that the defendant came to

her on 14th November, 1944, complaining of pain in the right side of the abdomen and said that she had previously had pain in the left side of the abdomen. The defendant informed the physician that her last menses was on 4th October, 1944, and that the last time she had seen her husband was 24th April, 1944. The physician advised her that the birth should take place about the end of January 1945. The defendant immediately wrote to her husband and informed his family as well as her own friends and family. On 5th February, 1945, when she examined the defendant, the physician said she found the head of the fœtus engaged, a position of the head which generally occurs about a month prior to birth. In the light of this testimony, said the court, the birth should have occurred about 5th March, 1945, which would have been 316 days from coition, a not improbable period of gestation. On 19th February, 1945, however, the physician again examined the defendant and, finding no sign of impending birth, recommended that the defendant go into a hospital. The defendant spent three days in a hospital, 28th February, 1st March and 2nd March, during which time she received treatment to induce labour. These treatments were ineffectual, however, and the defendant returned to her home, finally giving birth to a 9 pound child on 14th April, 1945. The physician stated that on every examination of the defendant the fœtus was small.

It thus appears, said the court, that while the duration of pregnancy was 355 days, the head of the fœtus was engaged for at least 68 days, which presents a question as to whether the last forty days were a part of the period of gestation proper or were due to difficulty in delivering the child.

In an English case decided in 1921, there was no evidence of misconduct on the part of the wife except the lapse of time between coition and the birth of the child, which was 331 days. Three leading medical authorities testified that such an interval could not be said to be impossible. Viscount Birkenhead in dismissing the petition said:

In this case the only evidence of adultery is the admittedly abnormal length of pregnancy. No other fact or circumstance has been adduced which in the slightest degree casts any reflection upon the chastity or modesty of the respondent, who has, on oath, denied the alleged adultery. I can only find her guilty if I come to the conclusion that it is impossible, having regard to the present state of medical knowledge and belief, that the petitioner can be the father of the child. The expert evidence renders it manifest that there is no such impossibility. Under these circumstances I accept the evidence of the respondent and find that she had not committed adultery, and accordingly I dismiss the petition.

The New York court said that the presumption of legitimacy is one of the strongest and most persuasive known to the law. Even aside from this presumption, however, having regard to the evidence in this case and the present state of medical knowledge and belief, it cannot be said that it is impossible that the plaintiff is the father of this child. The expert evidence, plus the fact that the head of the fœtus was engaged for 68 days when birth normally occurs within a month after such engagement, 'renders it manifest that there is no such impossibility'. The court accordingly rendered judgment in favour of the defendant and dismissed the complaint.

BLOOD GROUPING TESTS HELD NOT TO BE CONCLUSIVE EVIDENCE OF PATERNITY

(Abstracted from the *Journal of the American Medical Association*, Vol. 133, 15th February, 1947, p. 498)

THE plaintiff, by her guardian *ad litem*, commenced a bastardy proceedings against the defendant for the

purpose of obtaining allowances for medical care, support and attorney's fees. From adverse portions of the judgment, the defendant appealed to the district court of appeal, second district, division two, California.

Prior to the plaintiff's birth, her mother and the defendant entered into a stipulation providing, among other things, that within four months after the birth of the child the plaintiff, the mother and the defendant would all submit themselves to a blood grouping test by certain physicians chosen in accordance with the provisions of the stipulation. The purpose was to determine the paternity of the child, and the stipulation was signed by the plaintiff's guardian *ad litem* and by the defendant. After the plaintiff's birth the tests were made, the physicians, whose qualifications, competence and integrity are not questioned, reporting as follows :—

Examination of the bloods of Charles Chaplin, Joan Berry and Carol Ann Berry give the following results :

	Group	Type
Charles Chaplin	O	MN
Joan Berry	A	N
Carol Ann Berry	B	N

Conclusion reached as the result of these blood grouping tests is that in accordance with the well-accepted laws of heredity, the man, Charles Chaplin, cannot be the father of the child, Carol Ann Berry. The law of heredity which applies here is 'The agglutinogens A and B cannot appear in the blood of a child unless present in the blood of one or both parents'.

Two of the physicians testified at the trial that the report truly represented their findings from the tests made. They and one other physician testified that by reason of said tests defendant was not and could not have been the father of the plaintiff.

Were the blood tests conclusive that defendant was not the father of the plaintiff? The court held that they were not and based its holding on *Arias v. Kalensnikoff*, 10 Calif (2d), 428, 74 p. (2d), 1043, the only reported case in California in which blood tests were used for the purpose of attempting to determine the parentage of a child. In that case the court held that the evidence concerning the blood test 'is expert opinion, because the conclusions reached by the examiner are based upon medical research, and involve questions of chemistry and biology with which a layman is entirely unfamiliar', but that such tests and the evidence thereof are not conclusive because not so declared by the code and further that expert testimony is to be given the weight to which it appears to be justly entitled. Continuing, the district court said, conceding the immutability of the scientific law of blood grouping, which we have no reason to question, the infallibility of the results of blood tests depends upon the skill employed in making them. Errors are reported due to (1) the lack of training of the serologist; (2) the use of commercial serums; (3) the failure to make a countertest. When scientific testimony and evidence as to facts conflict, the jury or the trial court must determine the relative weight of the evidence. The law makes no distinction between expert evidence and that of any other character. The decision in the *Arias* case, concluded the court, has been the subject of discussion and criticism in law reviews and other legal periodicals but not by other courts as far as we have been able to ascertain, and it remains the law of this state until modified or overruled by the court that rendered the opinion. Accordingly, the judgment in favour of the plaintiff was affirmed.

In a specially concurring opinion, one of the Supreme Court judges announced that he concurred in the judgment because of the fact that the court was bound by the decision of the Supreme Court in *Arias v. Kalensnikoff* but added that he believed that the Supreme Court was in error in its determination of that case. In his specially concurring opinion he said that the ascertainment of the factual truth in the

adjudication of any controversy is a consumption devoutly to be wished. Time was when the courts could rely only on human testimony. But modern science brought new aids. The microscope, electricity, x-ray, psychology, psychiatry, chemistry and many other scientific means and instrumentalities have revised the judicial guessing game of the past into an institution approaching accuracy in portraying the truth as to the actual fact where, in the pursuit of which, scientific devices may be applied. The chemical tests for learning the presence of poisons in the blood stream, application of the roentgen ray in defining the fracture of a bone, the use of the microscope in acquiring exact knowledge of the authorship of documents, of the presence of bacteria or of the prevalence of white corpuscles—all argue eloquently for a reliance on scientific devices for truth. If the courts do not utilize methods for acquiring accurate knowledge of pertinent facts, they will neglect the employment of available potent agencies which serve to avoid miscarriages of justice. In conclusion the concurring justice said in the case at bar a widely accepted scientific method of determining parentage was applied. Its results were definite. To reject the new and certain for the old and uncertain does not tend to promote improvement in the administration of justice.

Reviews

PRACTICAL PHYSIOLOGICAL CHEMISTRY.—By Philip B. Hawk, Ph.D., Bernard L. Osor, Ph.D., and William H. Summerson, Ph.D. Twelfth Edition. 1947. J. and A. Churchill Limited, London. Pp. xiv plus 1323 with 329 figures and 5 plates. Price, 50s.

This popular book has reached its twelfth edition, the first edition having been published in 1907. The number of editions that it has passed through is sufficient proof of its usefulness.

The book has been divided into 36 chapters and an appendix. It is indeed a pleasure to read this new volume. The authors have revised the book in a very thorough manner to bring it abreast with the recent advances in physiological chemistry. Many new items have been added and new tests described. The introduction of new sections on the polarigraph, on isotopes, on the Warburg tissue-slice procedure, on metabolic antagonists and antibiotics, on the sulfa drugs, on the electrophoretic fractionation of the plasma proteins, on the composition of foods, etc., has greatly enriched this book. Useful informations have been incorporated on many recently introduced drugs and new illustrations have been added. The appendix has been thoroughly rewritten with important additions. It contains a good deal of information which is of great help to the laboratory worker. One can rely on this book. The get-up is very good.

The authors have to be congratulated for bringing out this up-to-date edition which we recommend unreservedly.

P. D.

EXPERIMENTAL PHYSIOLOGY FOR MEDICAL STUDENTS.—By D. T. Harris, M.D., D.Sc., F.Inst.P. Fourth Edition. 1947. J. and A. Churchill Limited, London. Pp. xi plus 298, with 257 illustrations and plate in colour. Price, 18s.

This ideal book for practical work on physiology consists of 18 chapters besides a good introduction containing a group of exercises for selection of experiments for practical work. The chapters on the circulation, especially, are very valuable as those will

give the students a very good knowledge of the basic subject. Useful experiments have been described on the central nervous system and sense organs. The experiments described will give the students a good insight into the subject of physiology. Many of the exercises are of applied nature and will increase the interest of the students for the study of medicine. The inclusion of chapter XVIII on exercises in experimental pharmacology has increased the usefulness of this book. The diagrams given are simple and adequate. The paper and printing are excellent and the price moderate.

P. D.

PHARMACOLOGY AND THERAPEUTICS.—Originally written by Arthur R. Cushney, M.A., M.D., LL.D., F.R.S. Thirteenth edition thoroughly revised by Arthur Grollman, A.B., Ph.D., M.D., F.R.C.P., and Donald Slaughter, B.S., M.D. J. and A. Churchill Limited, London. 1947. Pp. 868 with 74 illustrations. Cloth price, \$8.50

CUSHNEY's textbook on pharmacology has been an authoritative work on the subject since 1899. Professors C. W. Edmunds and J. A. Gunn prepared the ninth to twelfth editions and the present editors were appointed to prepare the next edition after the death of Professor Edmunds and resignation of Professor Gunn.

The editors have aimed at writing a textbook of pharmacology for students and practitioners of medicine, a compendium of pharmacological knowledge. In recent years pharmacology has progressed extensively in almost all its aspects. This has involved considerable enlargement and revision of the text. The sections on chemotherapy, endocrines and vitamins have been rewritten. The vitamins particularly have been described in fuller detail than is usual in the textbooks of pharmacology. Most of the new remedies of proved therapeutic value have been described. In describing the actions of drugs more stress has been laid on evidences obtained from clinics than on those from laboratories of animal pharmacology. The chemical formulae and structure of the drugs have been extensively given. By wise pruning of discussion and deletion of much of the pharmacology on isolated organs the editors have succeeded in keeping the size of the book convenient in spite of the incorporation of the many newer drugs.

In a book which is so extensively used by students of medicine more precise direction regarding administration of drugs would have been welcome. Granuloma inguinale (p. 162) is not caused by a *Leishmania* organism but by a bacterial parasite of the Friedlander group. A fuller discussion as to the mechanism of absorption of iron is demanded from 'Cushney's' book. Toxic action of mercurial diuretics has not been mentioned. The modern synthetic ointment bases certainly merit a place in a book of this size.

The book will continue to maintain its pre-eminent position as a textbook of pharmacology for students of medicine.

J. C. G.

THE INDIAN PHARMACOPŒIAL LIST, 1946.—Published by the Government of India, Department of Health, New Delhi

The list has been compiled by the Indian Pharmacopœial List Committee under the chairmanship of Colonel Sir Ramnath Chopra appointed by the Drugs Technical Advisory Board with the approval of the Government of India at the instance of the Government in 1944. The preparation of the list was conducted under great stress and pressure as the government fixed only six months or so for the submission of the list in its final form.

In its general plan it follows the practice of the British Pharmacopœia—synonym, Indian name, source and preparation, composition, characters, tests of identity and purity, assay, storage, preparation and dose in metric and English units. In accordance with

the terms of reference the committee have included only those drugs in use in India which although not included in the British Pharmacopœia are of sufficient medicinal value in the list. It also includes Indian substitutes of some of the B.P. drugs which, though they do not conform to the B.P. standard of purity, possess equal medicinal properties. It further includes B.P. drugs of Indian origin which differ in minor points from the B.P. standards. Standards for certain substances used in medical practice of animal and bacterial origin manufactured in India have been described. The committee have opined that the scantiness of reliable and accurate chemical, pharmacological and controlled clinical data made the task of selecting drugs of sufficient medicinal value and describing their tests of purity and identity very difficult. There is bound to be difference of opinion about some of the drugs in the list but that the committee has succeeded so remarkably in compiling such a useful list with all the useful data in such short a time is a matter of great credit to the committee.

We hope that in no distant future an Indian Pharmacopœia will be compiled by the Pharmacopœia Committee.

J. C. G.

RADIUM DOSAGE: THE MANCHESTER SYSTEM.—

Edited by W. J. Meredith, M.Sc., F.Inst.P. 1947. E. and S. Livingstone Limited, Edinburgh. Pp. vii plus 124 with tables. Illustrated. Price, 15s.; postage, 8d. (home)

THIS most valuable book includes and summarizes a number of papers by Dr. Ralston Paterson and his co-workers at the Holt Institute in Manchester. These papers date from 1934 onwards, many of them having been published in the *British Journal of Radiology*. The first papers in this series published by Paterson and Parker pointed out the necessity for an accurate dosage system based on R units. A dosage system was worked out showing distribution of radium needles or containers for application in the form of moulds, or interstitially, the latter form in plane and volume distribution.

A large number of clinical applications are described, and in separate chapters the underlying physical principles are given.

Sets of tables are given at the end of the book from which the actual dosage to any particular lesion can be worked out with considerable accuracy.

The authors are to be congratulated on the lucidity of the text; the whole subject has been simplified in a most gratifying manner. This is a book which should be in the hands of every radiotherapist or surgeon who uses radium.

GYNÆCOLOGY WITH A SECTION ON FEMALE UROLOGY.—By Lawrence R. Wharton, Ph.B., M.D. Second Edition. 1947. W. B. Saunders Company, Philadelphia and London. Pp. xxi plus 1027, with 479 illustrations. Price, 50s.

THIS is a very recent publication of great value to the practitioner and to the student. The book has several new features. The first that strikes one as an innovation is the distribution of the subject-matter in such sections as:—1. Anatomy and supporting structures. 2. Physiology and functional disturbances. In other words—Anatomy and Applied Anatomy, Physiology and Disturbed Physiology have been dealt with side by side. There is a section on 'Childbirth Injuries'—definitely a new approach to the stereotyped description of prolapses and displacements. In section VI—misplacements of the uterus and fistulas have been dealt with. It is not usual for these subjects to be described in the same chapter. The same remark applies to section XIII which deals with endometriosis, sterility, extra-uterine pregnancy and abortion. What is the common factor amongst these subjects is not easy to comprehend. If yet another example was needed of this unusual grouping one can mention section XV which deals with post-operative care and normal hygiene of healthy women. Female urology has been

dealt with extensively. This really comes under genito-urinary surgery—though not strictly coming under the domain of gynaecology. In fact, chapter LXI is dealt with in obstetrics and most of the other chapters contain subject-matter for a textbook in surgery. This is a special feature of the book and will be appreciated by a practising gynaecologist who may not always have a treatise on surgery available for ready reference.

The subject-matter has been dealt with extensively. In the preface to the second edition the author says 'Significant changes and additions have been made . . . where physiologic or chemotherapeutic problems are under discussion . . .'

'Likewise I have always tried to present both sides of controversial questions'. This the author has done very completely and faithfully.

The text is profusely illustrated. The paper, the printing and the general get-up of the book are in keeping with the renowned publishers.

We have nothing but praise for this book. Practitioners and students of advanced courses of study will all derive considerable benefit from it. Though not a textbook, schools and colleges should keep it in their libraries.

M. S.

THE CIRCULATION IN THE FŒTUS (A SYNOPSIS FOR STUDENTS).—By K. J. Franklin, D.M., F.R.C.P., A. E. Barclay, O.B.E., D.M., F.R.C.P., F.F.R., F.A.C.R., and M. M. L. Prichard, M.A. Blackwell Scientific Publications, Oxford. Pp. iv plus 28. Illustrated. Price, 2s. 6d. Available from Messrs. Macmillan and Company, Limited, London.

The circulation in the foetus, by Kenneth J. Franklin and others, is a useful book for those who are interested in the development and physiology of the foetus and the new-born.

It gives the first-hand information of the research that is carried on in this very difficult but interesting system of the human body. The illustrations are clear and give an otherwise impossible to obtain visual experience of the circulation.

The book is small and well got up and makes easy reading. Researches of this kind only can advance the science of human physiology both before and after birth.

M. S.

THE CHILD BEARING YEARS.—By C. Scott Russell, M.A., F.R.C.S., M.R.C.O.G. 1947. Blackwell Scientific Publications, Oxford. Pp. vii plus 88, with 11 figures. Price, 7s. 6d.

This book written for the benefit of the general public is a small but comprehensive one. It gives information that will be useful for women from their girlhood till the end of the child-bearing years. So a large number of the population will be able to benefit from it.

The book deals both with normal and abnormal conditions. As it covers a large number of subjects, details in many places are not given. Any one interested in a specific subject should be able to get it from the references quoted in the book. The illustrations should help in understanding the physiology at different periods of a woman's life.

The book is handy, print is bold and neat and makes easy reading.

M. S.

THE BIRTH OF A CHILD : OBSTETRIC PROCEDURE IN NORMAL CHILD-BIRTH FOR THOSE WHO ATTEND WOMEN IN LABOUR.—By G. D. Read, M.A., M.D. 1947. William Heinemann (Medical Books) Limited, London. Pp. viii plus 89. Price, 5s.

This book written by the well-known author of the *Revelation of Child-birth*, Dr. Grantly Dick Read, is a very illuminating one. All those who are interested

in obstetrics, specially in the preventive obstetrics, will benefit immensely by this newer light on physiological labour.

Dr. Read's experience and his conviction of a painless labour is shown in the clear decisive way he has represented his view-point. The relationship between pain, fear and tension is very convincing. The part the correct psychology of the attendant can play in a successful painless labour is well explained. He is conscious of the time one has to spend and the trouble one has to take if we want to make the woman forget about the teaching of the past and convince her about the advantages of the present method of thinking.

The size of the book and the good print tempt one to read it. It gives many new ideas for those who are in touch with expectant mothers, and women in labour can practise the teaching in the book and help to obtain a painless happy termination of their pregnancy.

M. S.

ALLERGY IN THEORY AND PRACTICE.—By Robert A. Cooke, M.D., Sc.D., F.A.C.P. W. B. Saunders Company Limited, Philadelphia and London. Pp. 572, Illustrated. Price, 40s.

This book is the work of a pioneer and with the author are associated thirteen collaborators. It is based on the programme of post-graduate instruction in allergy sponsored by the American College of Physicians.

The immunological principles underlying allergy are explained lucidly. Practical details of procedures are ample and include serological subtleties like removal of complement without damaging a weak antibody in the serum.

Chapters on the disorders of the respiratory system are particularly arresting and cover nearly a quarter of the book. The description of Lupus Erythematosus Disseminatus is brief but informative and includes an unusual case beginning with asthma in a child. From this description, however, two queries arise : (1) Is the genito-urinary system 'normal' at all when there are present in the urine a trace of albumin and hyaline cases (p. 318)? (2) Is a disease to be regarded as 'potentially always fatal' if a case has been under observation for twenty-four years (p. 320)?

The book abounds in references. There are long lists of them after every one of the thirty-two chapters and an appendix. Each reference gives the title of the communication or of the book.

The paper, printing and binding are good; only one printing error (p. xi, para 3, line 1) has attracted the reviewer's attention.

All interested in immunology and allergy will do well to have this book in their bookcase.

S. D. S. G.

MATERIA MEDICA FOR NURSES.—By A. M. Crawford, M.D., F.R.F.P.S.G. Sixth Edition. 1947. H. K. Lewis and Company, Limited, London. Pp. vi plus 160. Price, 5s. 6d.

MATERIA MEDICA is a subject most nurses find very interesting and this 6th edition of *Materia Medica for Nurses* is a clearly set out and easily understood textbook. It is up to date with sections on sulphonamides, basal narcotics and penicillin, etc. Any nurse in training or qualified would do well to have this very excellent manual by her always as the author suggests in his preface to the first edition.

Convalescence

The building up of the system after illness, especially when anaemia and emaciation are present is definitely aided by the tonic — reconstructive action of Waterbury's Compound. This preparation presents products obtained by the enzymatic action of pancreatic ferments on cod liver oil, livers and spleens, malt extract and hypophosphites in a palatable form suited to the most fastidious palate. Waterbury's Compound improves the appetite and strengthens the digestive functions.

ATERBURY'S COMPOUND

In Pruritus Ani, Anal Fissure, Neuritis, Lumbago, Etc.

Proctocaine (procaine, 1.5; butyl-*p*-amino-benzoate, 6; benzyl alcohol, 5; vegetable oil to 100) is a non-toxic local anæsthetic with immediate effect which may last 28 days. It prevents all reflex movement during the critical period after operations such as those for piles and for anal fissure. It is valuable in pruritus ani, anal fissure, anal spasm, minor rectal operations, hæmorrhoidectomy and the pain afterwards, fibrositis (muscular rheumatism, including lumbago), sciatica, trigeminal neuralgia, eye pain, and crushed limbs.

organs and their functions. The second part of the book covers a wide field and deals with the principles of nutrition, the constituents of food, their uses in the human body, composition of foodstuffs, balanced diet, cooking, etc., all presented in a lucid style so as to make the subject intelligible to an average person. He will find that it is possible to obtain sufficient nutrition from the common foodstuffs that are still available to us, and what is equally important, he may be stimulated to take more interest in increased food production in which we are behind many other countries. The book is based on common sense, is easy to read and should prove useful to busy practitioners too. We would suggest that in the next edition some assorted menus may be given as examples of balanced diet; this may arouse further interest in the subject. One criticism we wish to make is that the author is inclined to put too much emphasis on the value of fasting in diseases. Fasting has undoubtedly its uses, is often overdone and it should have been made clear that prolonged fasting may lead to consequences more serious than the disease itself.

R. N. C.

CLINICAL EXAMINATION OF THE NERVOUS SYSTEM.—By G. H. Monrad-Krohn, M.D. (Oslo), F.R.C.P. (Lond.). Eighth Edition. 1947. H. K. Lewis and Co., London. Pp. xx plus 380 with 126 illustrations. Price, 16s. net

In this little book which is 'not intended to be a book on the diagnosis of nervous disorders', medical men will find much useful information obtained by clinical methods slightly different from those usually found in English medical literature. The author does not agree with the student reading a book before studying cases. One does not agree with the author.

The chapter on the intelligence quotient is not very instructive.

A significant advance is the angiography of the brain. Its utility, however, has been questioned.

The get-up could be better. The price is reasonable.

S. D. S. G.

MEMORANDA ON MEDICAL DISEASES IN TROPICAL AND SUB-TROPICAL AREAS. Eighth Edition. 1946. His Majesty's Stationery Office, London. Pp. 396 with 76 figures and 37 plates. Price, 7s. 6d. net

As memoranda it is an excellent publication. One admired it as a lieutenant and one recommended it to other lieutenants as a lieutenant-colonel. A military medical officer should not be without it. A medical man in civil practice and employment keen on acquainting himself with recent advances in tropical medicine, such as are applicable to daily routines, cannot do better than to obtain a copy. In its 396 pages (including the index) he will find a wealth of information probably not to be found in any other volume of this size. Instances are paludrine, *Plasmodium ovale*, homologous serum jaundice, vector of the jungle yellow fever and anti-rabic serum prophylaxis (anti-rabies is a better term).

As a complete textbook on tropical medicine it should not be judged. It would be better to let the word 'Memoranda' appear again on the binding in the next edition, as it appears on the title page now.

In the memoranda the essential has been separated from the non-essential, truly soldier-wise, for the benefit of the medical man who is already interested in the subject.

An excellent publication.

S. D. S. G.

NUTRITIONAL DISORDERS OF THE NERVOUS SYSTEM.—By John D. Spillane, E. and S. Livingstone Ltd., Edinburgh. Pp. 280. Price, 20s.

Among laboratory workers on nutrition there are many enthusiasts—mostly biochemists—and a few cynics—mostly clinicians. The clinician author of this

monograph holds the scales even between them for the benefit of the reader. The latter will find presented to him in a readable form a critical review of the vitamin-B complex, and up-to-date developments in the morbid anatomy of neurology in general with emphasis on encephalopathy, subacute combined degeneration of the cord, polyneuritis and beri-beri.

The scales are held so even that often the reader wonders if the cynics (or even the enthusiasts) are not right after all.

An appendix of 54 pages gives a record of the author's own cases. There are several pages of references and two indexes, author's and general.

Some accounts are rather spread out more than is necessary. On pages 57 and 58 Kagawas is allowed four consecutive paragraphs. Then there are some obscurities: (1) What exactly is the difference between experimental degeneration of the cord in animals and the sub-acute combined degeneration in man—p. 107? (2) What is meant by 75 lentils per week—p. 179? (3) 'Thirty-five pellagrins, 50 per cent of whom were insane'—p. 38?—There are minor flaws. General conclusions are informative.

The book can be recommended to all interested generally in neurology and particularly in tropical neurology which differs markedly from what one learns from European textbooks on medicine.

The paper, printing and binding are excellent. No printer's errors attract attention. The price is reasonable.

S. D. S. G.

PRACTICAL POINTS IN PENICILLIN TREATMENT.

—By G. E. Beaumont, D.M. (Oxon.), F.R.C.P. (Lond.), and K. N. V. Palmer, M.B. (Cantab.), M.R.C.P. (Lond.). Second Edition. 1947. J. and A. Churchill Limited, London. Pp. 18. Price, 1s. 6d.

This is the second edition of a pamphlet issued last year and reviewed in this journal. New matter covering a page and a half has been introduced.

Two doses of 250,000 units of penicillin in water, one in the morning and one in the evening, have also been recommended, instead of the 3-hourly administration. The rest of the account appears to be the same.

The two categories of diseases, one in which the antibiotic is indicated and the other in which it is not, are given again. Anthrax has not yet been included in the first. It is not included in the second either.

A useful publication.

S. D. S. G.

MENTAL HEALTH.—By John H. Ewen. Edward Arnold and Co., London. Pp. 270. Price, 12s. 6d.

This book gives a concise account of the salient features of mental illness as a whole in an easy narrative. It is written not only for medical students and practitioners but also for those who are interested in sociology, education, child welfare and delinquencies of all sorts.

Under etiology the views of Freud, Jung, Kempf and Adler are compared and contrasted lucidly and amply, in the psychogenic theory of mental disorders. The normal and abnormal solutions of the conflict are discussed.

The bodily causes are not ignored though their inadequacy is pointed out: Drugs are rather indicative of mental instability than causative; auto-intoxication and focal sepsis have been over-rated in the past; and bodily diseases and exhaustions may act as precipitating causes.

The symptomatology conjures up moving pictures: Let the dreamer walk about and act like one awakened and we have the clinical picture of dementia praecox (schizophrenia).

The treatment mentions all up-to-date measures, including the electrical convulsion treatment and narco-analysis. Details of some measures are also available.

The get-up is excellent and price reasonable.

Abstracts from Reports

ANNUAL REPORT OF THE BENGAL BRANCH OF THE BRITISH EMPIRE LEPROSY RELIEF ASSOCIATION FOR THE YEAR 1946

THE main activities of the Bengal Branch consist in carrying out surveys, doing leprosy propaganda, training medical officers in the diagnosis and treatment of leprosy, giving lecture-demonstrations in leprosy to the senior students of the medical institutions of the Province, and inspecting leprosy clinics run by the district boards, etc.

The Bengal Government set up a Committee to report on the future organization of anti-leprosy work in Bengal, with the Director of Public Health as Chairman and Dr. Dharmendra as Secretary. The Committee considered the existing leprosy problem and anti-leprosy work in the Province, and made recommendations for the improvement and the extension of these activities. A summary of the recommendations of the Committee is given below :—

1. The Government should accept the principle that the control of leprosy in the Province is its direct responsibility.

2. For the purpose of anti-leprosy work, the Province of Bengal should be divided into twelve units: (i) Midnapore; (ii) Bankura; (iii) Burdwan and Hooghly; (iv) Birbhum; (v) Calcutta and Howrah; (vi) Murshidabad and Nadia; (vii) 24 Parganas, Jessore and Khulna; (viii) Rajshahi, Malda, Dinajpur, Bogra and Pabna; (ix) Rangpur, Darjeeling and Jalpaiguri; (x) Dacca, Faridpur; (xi) Mymensingh; and (xii) Noakbali, Tippera and Chittagong Hill Tracts.

3. A senior officer of the status of Deputy Director of Public Health should be attached to the Directorate of Public Health, for anti-leprosy work. This officer, who may be designated as Provincial Leprosy Officer, or by some other name, should direct, supervise and co-ordinate the whole leprosy work in the Province. The Provincial Leprosy Officer should be assisted by a District Leprosy Officer in each unit, and a District Leprosy Officer should have under him the necessary number of Assistant Leprosy Officers and Field Assistants.

4. There should be established at least one leprosy institution for infective cases in each unit, with an accommodation for 500 to 1,000 patients. In some units, for example Bankura, Midnapore and Birbhum, there will be needed more than one institution. One of these institutions should play a leading part in teaching and research in the Province.

5. The other activities in the units include an increase in the number of leprosy clinics, organization of village isolation centres, provision for making leprosy surveys, special homes for children, leprosy asylums for crippled and derelict cases, etc.

6. In places where there are no leprosy clinics, the treatment of leprosy should be made available at the Government and District Board hospitals and dispensaries. In addition, the mobile dispensaries in the Province should include in their scope the treatment of persons suffering from leprosy.

7. Leprosy patients, if needing temporary hospitalization for diseases other than leprosy, or acute complications of leprosy, should be admitted into general hospitals, infective cases into infectious wards, and non-infective cases into general wards.

8. The present arrangement whereby teaching in leprosy in the medical institutions is done by the Bengal Branch of the British Empire Leprosy Relief Association, should continue till proper arrangements are made for the teaching to be done by a regular member of the staff with experience and training in leprosy.

The present arrangement whereby post-graduate teaching is done at the Leprosy Department of the School of Tropical Medicine, Calcutta, should continue till the proposed Provincial Leprosarium can undertake it efficiently.

The proposed Provincial Leprosarium should also arrange for the training of non-medical personnel required in anti-leprosy work, e.g. health visitors, nurses and social workers.

9. The existing legal powers for the control of leprosy are not of much practical value, and it is essential that a fresh comprehensive act should be enacted, incorporating the existing and the projected legislation. An indication has been given in this report of the lines on which this legislation should be drafted.

10. Research into the treatment and control of leprosy in an important anti-leprosy activity, and should be given due attention at the proposed Provincial Leprosarium.

11. Anti-leprosy activities in the Province will be successful only if backed by educated and strong public opinion. For this purpose there is a great need for publicity on right lines. The present activities in this direction should be greatly extended, and modern methods of publicity should be utilized.

12. In addition to the medical and public health problems, leprosy creates important social and economic problems. For the success of anti-leprosy work, it is essential that due attention be paid to the solution of these problems. In addition to the provision made for crippled and derelict cases of leprosy, and the children of infective parents, there should be provision to help the needy dependants of the patients, and the able-bodied non-infective patients who may find themselves in difficulty. For the last mentioned purpose, it is desirable to have a special colony for the able-bodied non-infective cases of leprosy, specially cases discharged from the leprosy institutions.

13. Even with the expansion of anti-leprosy work of the Government to the fullest extent, there will be need and scope for work by voluntary and popular organizations. It is recommended that the Government should stimulate and help such voluntary organizations.

14. A start should be made with the appointment of a Provincial Leprosy Officer. Gradually, Leprosy Officers in the units should be appointed starting with the districts affected most, i.e. Bankura, Midnapore, Birbhum and Burdwan. Of the proposed leprosy institutions, a start should be made with at least 4, the Provincial Leprosarium near Calcutta, 1 each for Bankura and Midnapore, and 1 for the Dacca Division. The aim should be to complete the programme outlined in this report in the next 10 years, at the expiry of which the progress of the work should be reviewed and further programme outlined.

The Bengal Government has accepted the report and has already appointed an Assistant Director of Public Health for Leprosy. Two leprosy institutions with provisions for 500 cases each are expected to start working shortly.

Between the years 1932-37, Dr. B. N. Ghosh, Leprosy Officer of the Bengal Branch, British Empire Leprosy Relief Association, carried out leprosy surveys amongst beggars, school students, members of the Police Force, and workers of certain industrial concerns in Calcutta. He examined 3,000 beggars and detected 376 cases of leprosy, an incidence of over 12 per cent. Amongst the 25,000 students of High English Schools, he detected 109 cases of leprosy, an incidence of 0.4 per cent. In 13,000 students of Primary Schools, 135 cases were found, giving an incidence of 1 per cent. In over 5,000 members of the Calcutta Police, 47 cases of leprosy were detected, giving an incidence of 0.92 per cent. In over 9,000 workers of three industrial concerns, 150 cases of leprosy were found, giving an incidence of 1.65 per cent. It may be roughly said that the incidence of the disease in Calcutta as a whole is about 0.5 per cent.

The two clinics run by the Premananda Leper Dispensaries deal with over 2,000 persons annually, including cases amongst both the general population and the beggars of the city. Their report for the year 1945 shows that during the year a total number of 2,436 cases were treated from amongst the general public. Of this 1,172 were 'new' cases registered during the year. Of the 'new' cases, 864 are reported to have come from inside the city, and the remaining from outside the city.

During the 10 years 1936-45 over 8,000 permanent residents of Calcutta have attended the Premananda Leper Clinics and the Leprosy Clinic of the School of Tropical Medicine, for diagnosis and treatment of leprosy. An analysis of these persons according to the wards in Calcutta is given.

Correspondence

AN UNUSUAL CASE OF SUPPRESSION OF URINE

SIR,—Reference to above article published in the *I.M.G.*, August 1947, p. 472.

It is usually understood by the term 'suppression of urine' as the failure of the kidneys to secrete urine. The case under report is one of retention of urine, i.e. the failure of a full bladder to empty itself. Can you kindly clarify the position with regard to usage of these terms?

Yours truly,

B. S. RAMAMURTHI, M.S.
F.R.C.S. (Edin.).

43, HARRIS ROAD,
MADRAS.

[It is regretted that the above correction escaped notice.—EDITOR, *I.M.G.*]

PARKINSONISM IN TYPHOID FEVER

SIR,—With reference to the report in your journal of March 1947 of a case of typhoid fever, complicated by Parkinsonism, I wish to draw your attention to the following points:—

To me, the case looks one of typhoid with signs of meningeal irritation, the points in favour of the latter being

1. Muscular rigidity,
2. Positive Kernig's and Brudzinski's signs, and
3. C.S.F. findings, namely increased pressure, increased proteins, i.e. 1.2 per cent, complete absence of sugar and the presence of a few monocytes.

The cause of meningeal irritation is not quite obvious here. It cannot be the simple case of meningism, as there is a definite increase in the C.S.F. proteins, complete absence of sugar, and the presence of some cellular reaction though the clinical course of the case very much favours this diagnosis. In view of the otitis media or mastoiditis complicating the case, we have to think of: (1) Septic meningitis which is ruled out in this case by the absence of a marked polymorphonuclear cell reaction and growth in culture; (2) 'Serous' meningitis which is difficult to exclude in this case (granting the existence of such a pathological entity).

Though mentioned as a rather rare complication and as being attended with grave prognosis, typhoid meningitis has got to be thought of. The issue could have been settled if only the C.S.F. has been collected straight into ox-bile medium and cultured for *Eberthella typhosa*.

The total absence of sugar in the C.S.F. militates against a diagnosis of encephalitis the aid of which the author invokes in this connection. I wish the author had been a little more clear about the nature of the inflammation in question.

In this connection, I do not think the report of a similar case from the Government General Hospital,

Madras, will be out of place. K., about 25 years old, was admitted in the Enteric Ward under Dr. A. Sreenivasan, M.R.C.P. (London), Honorary Physician, for continuous fever of one week's duration. On admission the patient was very toxic and delirious. His temperature was 101°F., pulse 90 per minute, regular with good volume and tension. His tongue was coated all over except in the tip and edges. There was no distension of the abdomen or palpable liver or spleen. The respiratory and cardio-vascular systems were normal. He had almost cadaveric rigidity of the whole body musculature and it was somewhat of the 'cogwheel' type, Kernig's and Brudzinski's signs were positive. There were fine tremors in both the hands and they were present even during sleep. They were not of the 'intention' variety. The knee and ankle jerks were slightly exaggerated and the plantar response was flexor on both sides. Both the pupils were normal in size, regular, equal, reacted to light and convergence.

Investigations:—

Urine: Nil abnormal.

Blood: No malarial parasite detected in a smear.

Total W.B.C. count 10,800 per c.mm.

Polymorphs 76 per cent, lymphocytes 21 per cent, monocytes 3 per cent.

Lumbar puncture revealed clear fluid, not under tension. Queckenstedt's sign was positive. There were no cells in the fluid and there was no growth in culture (culture for enteric group was unfortunately not put up due to oversight). Total proteins 60 mgm. per cent. Globulin present, sugar 50 mgm. per cent, calorides 600 mgm. per cent. The lumbar puncture was repeated 2 days later for getting the C.S.F. for culture for enteric group. As ill luck would have it, the fluid was blood-stained due to trauma. VIDAL REACTION: Agglutination with *B. typhosus* 1 in 200 positive and with *B. paratyphoid A* and *B* negative. BLOOD CULTURE: *E. typhosus* was isolated.

The patient was put on a simple diaphoretic mixture with tincture stramonium 45 minims per day. On the 5th day of the treatment tincture stramonium was stopped, as there was no clinical improvement. The temperature touched normal on the 8th day of admission. The patient's general condition improved and along with it the rigidity and tremors also. The patient was able to answer questions quite well. The rigidity and tremors were totally absent on the 14th day after admission.

This case is very much akin to the one in question, except for the presence of tremors. Therefore, I again feel the same way here also. Tremors are not uncommon in cases of typhoid fever with meningeal irritation. The rapid and complete recovery, lowering of the C.S.F. chlorides, absence of growth in culture and absence of cellular reaction strongly favour the diagnosis of meningism in this case, the only point against this diagnosis being a slight increase in the C.S.F. proteins with presence of globulin.

I tender my grateful thanks to Dr. A. Sreenivasan, M.R.C.P. (London), for kindly going through this communication and also the Superintendent, General Hospital, and the Surgeon-General with the Government of Madras, for granting me permission to report the case from the Government General Hospital, Madras.

K. BHASKARAN,
M.B., B.S.

GOVERNMENT GENERAL HOSPITAL,
MADRAS.

SPECIFIC FOR ORIENTAL SORE (DERMAL LEISHMANIASIS)

SIR,—After many baffling efforts with injections and surgical interference I found local application of 1.5 per cent sodium antimony tartrate solution in gauze with daily renewal completely successful, satisfying all the conditions of a specific. Striking on the toxicity that is 1.5 per cent was the crucial thing, tipping the balance in favour of cells without irritation. Cases with heavy secondary infections were washed with 1 in 1,000 aqueous

acridavine lotion before application of gauze soaked in 1.5 per cent sodium antimony tartrate solution.

Yours sincerely,
N. Z. KHAN, M.B.
(MAJOR, I.M.S.-ex).

58B, PARK STREET,
P. O. CIRCUS,
CALCUTTA,
24th December, 1947.

[Sodium antimony tartrate and tartar emetic have been used from 1 to 4 per cent ointment for the treatment of oriental sore with considerable success. Some years ago a report was published from Delhi about this in this journal.

This letter would be useful if accompanied by convincing clinical data.—P. S. G.]

Any Questions

PENICILLIN IN WAX AND OIL

SIR,—Penicillin G in wax and oil according to Romansky formula contains 4.8 per cent wax. It liquefies at about 114°F. My questions are the following:—

1. Is the wax solid at body temperature when injected intramuscularly?
2. How the wax is absorbed from the muscle?
3. If not absorbed, can foreign body reaction or septic cellulitis in a devitalized patient be produced sooner or later?

Yours truly,
P. GHOSAL.

7, BHUT NATH HALDER
LANE, SIBPUR, HOWRAH.

1. Penicillin-oil-beeswax suspension ('P.O.B.') is sufficiently fluid at blood heat and the penicillin can be distributed uniformly by thorough shaking at that temperature.

2. Absorption of wax in the 'P.O.B.', if at all, is very slow.

3. The portion of wax not absorbed is encapsuled; the chance of septic cellulitis at the site of injection is, however, very remote unless the injection is repeated at the same site, and organisms permitted to enter through the skin puncture. There is no evidence to suggest that the local tissues get devitalized as a result of the wax forming a depot at the site of injection.

SMALLPOX WITH MALARIA

SIR,—Is it judicious to administer quinine to patients who, having attacks of malaria fever, are down with smallpox?

Is there any contra-indication of its (quinine) giving intramuscularly, 10 grains per dose, one or two injections

on the 1st or 2nd day of the onset of the disease, i.e. before coming out of the rash, if malaria is suspected?

Yours faithfully,
S. C. CHAKRABARTI, L.M.F.

M. O., NEPAL GOVT.
RAILWAY, BIRGUNJ,
RAXAUL P. O.

[Yes.

No contra-indication is known. But why intramuscularly and not by mouth?—J. C. G.]

VACCINATION AGAINST SMALLPOX

SIR,—In March 1947, a local vernacular paper reported that "several famous British doctors" had earnestly requested the Indian people and the Provincial Governments to eschew vaccination against smallpox, altogether, for the practice had done 'incalculable harm' to the British people. These doctors appealed to all concerned not to repeat the mistake made elsewhere and recommended the perusal of 'The Vaccination Problem' by one J. B. Swan.

Recently again (i.e. in the last week of December), an article has appeared in the vernacular press claiming that the practice of vaccination is 'unscientific, unnecessary and dangerous'.

At about the same time, during Conference Week in Bombay, a local paper there published the following letter—

'Doctor's attention

It is reported that nearly 740 delegates from India and Pakistan are meeting in Bombay for the All-India Medical Conference. Here is something to which the attention of all these Indian doctors is earnestly invited. British doctors have recently addressed a petition to the Legislative Assemblies of all the Provinces in India. An extract from that letter follows:—

"We, in England, after suffering bitterly for more than a century from the failure and the evil effects of vaccination, have, as the result of a hard struggle against prejudice, selfishness and the greed of vested interests, at last succeeded in freeing ourselves from the compulsory imposition of this practice and we now desire that our fellowmen in India shall also be free. . . . In this matter we feel we have a particular moral responsibility towards India, because it was the British Government in India who introduced vaccination into that country. Convinced that its introduction was a mistake, as has been amply proved by results, we now wish to take this opportunity to write you without wasting a hundred . . . did, to abolish compulsory vaccination in India. You will thus bring your country into line not only with England but also with other European countries, some of the states of North America and with Australia and New Zealand. Vaccination does not protect from smallpox, nor prevent deaths from the disease. Vaccination is a frequent cause of ill health and even of death. The real causes of smallpox are poverty, insanitary conditions and wrong feeding. In view of these facts we ask the Government to repeal the compulsory vaccination laws and to transfer the money and effort now less than wasted on vaccination and revaccination, to the increased support of national schemes of sanitary and social reform which alone can lead, not only to the abolition of smallpox but to the ultimate abolition of all the grosser forms of Zymotic disease. . . ."

—SCRUTATOR.

RANCHHODLAL DISPENSARY,
PANCHKUWA, AHMEDABAD,
COLABA.
6th January, 1948.

Yours faithfully,
K. A. SHAH.

[Such propaganda against vaccination for smallpox have appeared from time to time. They however produce no facts which would make them worthy of serious attention.—R. B. L.]

Service Notes

APPOINTMENTS AND TRANSFERS

THE following officers of the late I.M.S. were appointed by the Secretary of State to the I.M.S. (Civil) with effect from the dates noted against their names :—

Sind

Major E. M. Wallace. Dated 11th July, 1946.

Punjab

Major S. G. O'Neill. Dated 7th October, 1946.

Orissa

Lieutenant-Colonel B. N. Hajra. Dated 10th November, 1946.

The following officers are permanently transferred to the late I.M.S. (Civil) with effect from the dates noted against their names :—

Ministry of External Affairs and Commonwealth Relations and States

Major C. H. Bliss. Dated 14th February, 1947.

Major G. R. C. Palmer. Dated 13th March, 1947.

Ministry of Health

Major N. Jungalwalla. Dated 8th August, 1946.

Lieutenant-Colonel T. B. Pahlajani. Dated 1st January, 1947.

Lieutenant-Colonel W. T. Taylor. Dated 1st January, 1947.

Major B. A. Porritt. Dated 1st January, 1947.

Major H. B. Wright. Dated 1st January, 1947.

Major G. H. K. Niazi. Dated 1st January, 1947.

Sind

Major S. A. Hassan. Dated 22nd May, 1947.

Bengal

Major C. H. Dhala. Dated 22nd February, 1947.

Punjab

Major L. U. Kam. Dated 3rd February, 1947.

Major B. H. Sayeed. Dated 18th April, 1947.

Bihar

Major R. B. Davis. Dated 18th June, 1947.

Major A. S. Sen is appointed Assistant Director-General of Health Services (Stores) temporarily for 1 year with effect from the 2nd January, 1948.

LEAVE

Lieutenant-Colonel W. T. Taylor, lately Additional Deputy Director-General, Indian Medical Service (Stores), is granted combined leave preparatory to retirement for a period of 2 years and 4 months, viz. leave on average pay for 8 months and half-average pay for the balance, with effect from the 6th April, 1947.

Captain A. S. L. Narasimham. Dated 23rd September, 1946.

Captain M. G. S. Narayanan. Dated 17th October, 1946.

Captain V. K. Prabhu. Dated 28th October, 1946.

Captain Mohd. Iqbal. Dated 3rd November, 1946.

Captain O. K. D. Kesavan. Dated 3rd January, 1947.

Captain D. Krishnamurti. Dated 11th August, 1947.

Publishers' Notice

SCIENTIFIC Articles and Notes of interest to the profession in India are solicited. Contributors of Original Articles are entitled to receive 25 reprints gratis; additional reprints can be obtained on payment. No reprints will be supplied unless contributors ask for them at the time of submitting their manuscripts.

The preparation of reprints entails rearranging the type, so that there is often a delay of a month or more, after the publication of the *Gazette*, before the reprints are ready. If reprints are not received within two months of publication of the *Gazette*, contributors should write to the Publishers.

Papers and articles forwarded for publication are understood to be offered to *The Indian Medical Gazette* alone, and any breach of this rule will be followed by non-publication. When any such article appears in *The Indian Medical Gazette*, the copyright automatically becomes the joint property of the author or authors and of the publishers.

Communications on Editorial Matters, Articles, Letters and Books for Review should be addressed to THE EDITOR, *The Indian Medical Gazette*, c/o The Calcutta School of Tropical Medicine, Central Avenue, Calcutta.

Communications for the Publishers relating to Subscriptions and Advertisements should be addressed to THE PUBLISHERS, *The Indian Medical Gazette*, P. O. Box No. 54, Calcutta.

Annual Subscription to '*The Indian Medical Gazette*', Rs. 16 including postage, in India. Rs. 19-8 including postage, abroad. Single copies Re. 1-8 each. Back numbers (if available) for the previous year Rs. 2-8 each, and all other back numbers Rs. 5 each.

The Editors of *The Indian Medical Gazette* cannot advise correspondents with regard to prescriptions, diagnosis, etc., nor can they recommend individual practitioners by name, as any such action would constitute a breach of professional etiquette.
